7 of these patients had received physiotherapy totalling 35 weeks' inpatient and 56 weeks' outpatient treatment

All this staggering waste of professional time and public money was not merely useless to these patients, but actively harmful to them in that it confirmed original fears that they had some serious organic di In many cases it probably made them ther inaccessible to psychotherapy and condemned to a of invalidism

I suggest that this also is a tragic issue I s that while both these types of medical error are tr " the great tragedy " lies in the lack of that bala psychosomatic approach which would make a do as ashamed of missing a psychogenic disorder as he is of missing an organic one

London W 1

ALAN MCGLASH

MASKED EPILEPSY

SIR,—I have closely followed the arguments in rel to Dr Wallis's paper of Jan 8 If one agrees that in the leg, cyclical vomiting, headaches, pyrexia, abdominal pain are fairly common manifestation epilepsy, how far does this help in the treatment ? these cases the forerunners of Hallhuber's autono dystonias,[1] or the "*Manager-Krankheiten*" of the generation ?

I agree with Dr O'Neill (April 2) and his tension the These cases need more than phenobarbitone Bu exploration of the child's mental state and his envi ment must take too long and there are too few psy therapists I look forward to controlled research hypnotherapy Tension appears to be rapidly destro and the child is defended against himself As Bram says[2] " He becomes more in control of his organism."

London, W 1

GORDON AMBROS

SANATORIA

SIR,—I read Dr Edwards's letter last week interest While agreeing to a large extent with wha says, I think there is one factor he has not mention namely, that it is quite possible that in the near f patients will refuse to go to sanatoria many miles d from their homes

As regards teaching tuberculous patients " to with their disease," I would say that diabetic pat learn to live with their disease very satisfactorily wi having to go to special institutions for the pu Nevertheless, I quite agree that there is still a plac sanatoria in the treatment of tuberculosis, provided are near the centres of population that they serve.

Hastings

A W ANDERSO

THE DIFFICULT APPENDIX

SIR,—Every young general practitioner should the article by Mr Kerr in your issue of April 9, w reveals the many difficulties in such a common diso and older readers may be consoled over their failures, either in not operating soon enough or in rem ing a normal appendix Two of my own cases may th some light on our difficulties

One hot summer a 7 year old boy suffered from indig and diarrhœa He was still playing with his friends be he had no fever, pain, or vomiting, till sent home by an mother because he was incontinent of liquid fæces He put to bed by his doctor, who was told about generous of unripe apples Bismuth was prescribed Three days la though not complaining of any pain, he was admitted to pital suspected of salmonella infection (leucopenia splenomegaly, and diarrhœa) In a couple of days he se to improve He had neither fever nor pain, but a leucocy developed A surgeon concluded that there was no sur cause, and that the condition was probably paraty That night the boy collapsed with upper abdominal pain rigidity, black vomit, and meteorism A perforation suspected and the abdomen was opened, but a gangre rocæcal appendix and an abdomen full of pus was found boy died three hours later

[1] Hallhuber, M. J *Ars Medici, Liestal*, 1953, 43, 462
[2] Bramwell, J M Hypnotism. London, 1930

6-year-old girl complained of colic and vomiting Her perature was slightly elevated No typical muscular nce could be found in the abdomen but by palpating ply in the cæcal region some resistance was noted The endix was removed but it was only slightly red No hological examination was made. Her general condition riorated with continuous vomiting meteorism, and r When I first saw her the child was seriously ill with ched nose acetonuria, and leucocytosis (23 000 per c.mm h shift to the left and toxic granulations) X ray examina of the chest showed that the diaphragm was high moved poorly but there was no other abnormality An avenous drip of glucose-saline solution followed by plasma ed time for arguments to be considered in favour of ning the abdomen Within two hours the child underwent arvellous change; no vomiting no fever less meteorism. view was that this was a case of cyclic vomiting with tonæmia. Within a week the child was discharged fectly fit

Hilversum. D P R KEIZER.

POLIOMYELITIS VACCINES

ir,—The Salk anti poliomyelitis vaccine is prepared n monkey tissue cultures Is it certain that injection this preparation will not produce rhesus antibodies en injected into susceptible human subjects, most ecially those already sensitised ?

estminster School of Medicine
London, S W 1 J G HUMBLE

RUPTURE OF LAPAROTOMY WOUNDS

ir,—In reading Mr Standeven's article of March 12 l the subsequent correspondence I have been struck the lack of reference to what I believe to be a most ortant feature I have re sutured over 30 burst domens and in all cases I have noticed the firm erence of part of the prolapsed bowel or omentum the edges of the peritoneum and the subcutaneous ues. Surely this suggests that some part of the peritoneum has given way at an early stage Small gut or ntum protrudes and lies just deep to the skin itoneal fluid escapes and (I believe) delays healing the superficial layers When the skin stitches are oved the whole wound disrupts and more bowel may n prolapse

r Standeven and Mr Walsh (March 26) rightly s the significance of the serous discharge In my erience this always indicates an impending rupture ach cases inspection and percussion may demonstrate t small bowel lies just below the skin

believe that the most important layer of the ominal wall is the peritoneum Unfortunately it is the akest If the patient is straining at the time of its ure the peritoneum may split at right angles to line of suture In several cases I have found the ure line to be intact but bowel escaping just lateral it

doubt if the incidence of dehiscence of laparotomy unds is in any way influenced by such general factors anæmia or protein or vitamin deficiency—or even al sepsis. If the peritoneum stays intact there will no burst abdomen I feel therefore that Mr andeven s distinction between early and late ruptures an artificial one If the skin stitches are left in till te the skin edges will probably hold The later a rst abdomen occurs the more difficult it is to separate it of the bowel from the subcutaneous tissues

In my own experience I have found that :

(1) Transverse or oblique incisions are less likely to rupture an vertical ones because the pull of the abdominal muscles es not tend to separate the peritoneal edges

(2) The abdominal wall must be relaxed until peritoneal sure is complete

(3) Nylon is unreliable

(4) Short ends of knots must be left long and the gap between stitches kept short

(5) The peritoneum is less likely to split if a horizontal mattress suture is used

The London Hospital, E 1 A J WALTON

SIR,—Like other correspondents, I found catgut and monofilament nylon unsafe in suturing the rectus sheath Interrupted thread and silk was secure but tedious to insert For three years now I have been using continuous braided nylon (Finlayson's *no 6 green*) It is pleasant to use and so far safe Although there have been some infected wounds it has only once been necessary to remove the suture

Braided nylon has more elasticity than monofilament nylon so should be less likely to cause the tight feeling in the wound mentioned by Mr Oldham (April 16) This *sensation* has been *mentioned* by *only* one patient but has not been asked for specifically so may well be more common Certainly the knots are unobtrusive

London W 1 A. M DICKINS

HYPOGLYCÆMIC EFFECT OF DIMERCAPROL

SIR,—Concerning the preliminary communication by Dr Butterfield in your issue of March 5 the papers on sulphur and diabetes mellitus published by Prof Andreu Urra and myself from the medical clinic of the University of Seville are perhaps unknown in Britain These papers were based on a series of experiments which are the subject of my thesis on the problems of sulphur and uric acid in diabetes mellitus[1] Professor Urra and I have also published another paper on sulphur and the metabolism of glucosides in diabetes mellitus.[2] In these investigations low levels of glutathione were usually found in diabetic blood and experimentally alloxan diabetes was prevented by giving preparations of sulphur We treated diabetics with dimercaprol and found only a slight tendency to reinforce the action of insulin and hyperglycæmia and glycosuria improved

Seville MIGUEL RIOS MOZO

BURNS FROM ELECTRIC BLANKETS

Mr F Grisley B.SC managing director of the Warm Glow Co Ltd , writes :

In your issue of April 2 Dr Neville Davis reports an accident with an electric blanket To avoid risk of accidents the manufacturers normally instruct the user to switch off the blanket before getting into bed but people often disregard this advice Alternatively a waterproof sheet may be used between the blanket and the sleeper This also may be disregarded, or a worn or pervious sheet used with disastrous results. The use of an earth as suggested by Dr Davis, is impracticable and even dangerous for the blanket should be an earth free appliance with no exposed metal parts.

In 1948 my company introduced a plastic-covered waterproof element into all our blankets. This not only prevents danger from bed wetting, but it also enables the whole blanket to be immersed for laundering The plastic covering used is stable and flexible, and lasts indefinitely This particular kind of accident therefore need never occur

PLASTIC APPLIANCES MOULDED DIRECT TO PATIENT

Mr R A E. Walker secretary of the National Research Development Corporation writes

In his article of April 23 Dr Brennan refers in a footnote to patent application no 16668/51 It may not be clear to your readers that this application relates to the proposals communicated to us by Dr J T Scales of the Institute of Orthopædics Royal National Orthopædic Hospital Stanmore for the preparation of composite material of Polythene (polyethylene) and Moltopren (polyurethane) and the moulding of surgical splints therefrom by application to plaster casts or directly to the patient The patent rights in Dr Scales's invention have been assigned to the Corporation for exploitation in accordance with the Development of Inventions Act 1948 Application may be made to the Corporation for further particulars.

Obituary

EGBERT COLEBY MORLAND

M B, B Sc. Lond, M D. Berne, F R C P, F R C S
EDITOR OF THE LANCET, 1937-44

In the development of a journal a few men and women play outstanding parts The influence of Dr Morland's original mind and new points of view was apparent from the time he joined the staff of *The Lancet* in 1915, and it continues through those he taught

In few ways an ordinary man, he brought to his main task a knowledge and experience as unusual as it was useful

He was born on Sept 3, 1874, the fifth son of Charles Coleby Morland, J P, of Croydon, and his wife Jane Fryer The Morlands and the Fryers were Quakers from the North of England, and the Croydon family was both brilliant and unconventional Egbert, a clever but uneasy boy, was sent to the Whitgift Grammar School and then to Bootham, the Friends' school at York A taste for science was confirmed by a period at Owens College, which also gave him a lifelong bond with Manchester He took his B SC with first-class honours in zoology, and went on to St Bartholomew's Hospital with a senior scholarship At Barts he won the Matthews Duncan prize and was vice president of the Abernethian Society, and after taking the London M B in 1898, with the gold medal in physiology and honours in anatomy and organic chemistry, he became successively ophthalmic house-surgeon and house physician at his own hospital, and house-physician at Wolverhampton General Hospital His next appointment, in 1901, was at Great Ormond Street, and it was then that the natural sequence of his career was rudely broken He developed tuberculosis

Like many another medical victim of this disease, he presently found himself making it his special study The first fruit of this new interest was an essay on the design of sanatoria, entered for an international competition held in 1902 before the King Edward VII Sanatorium was built at Midhurst There were 180 competitors, and with the aid of his architect brother Morland gained third prize for his plans, which were published in the first issue of *The Lancet* for 1903 The new phase in his life was soon established, for after living for a while in Switzerland to recover his health he decided to remain and make his home in the mountains In 1903 he married Mary Windsor Latchmore, a woman of zest and character who helped him devotedly till her death in 1948, and when he had taken the Swiss Federal Diploma they settled at Arosa, where he practised in three languages and from 1907 to 1914 directed the Villa Gentiana, an English sanatorium In 1905 he was writing in these columns, with W R Huggard, on the action of yeast in tuberculosis and its influence on the opsonic index, and his M D thesis at Berne in 1907 was on *opsonins—a subject then in the bacteriological forefront* From the German he translated Turban's *Diagnosis of Tuberculosis of the Lung* and Bandelier and Roepke's *Tuberculosis in Diagnosis and Treatment* In 1913 he produced a small book, written with Clive Rivière, on *Tuberculin Treatment*, and a paper on technique of artificial pneumothorax

This phase was ended by the outbreak of war, and next began almost by chance Now some 40 years he left Switzerland to join in the Society of Fr relief work on the Marne Before doing so, however, had displayed his journalistic talent by abstracting *The Lancet* a statement by Paul Eltzbacher on food supply of the German people, and when twenty-column contribution arrived one day ju the journal was going to press, the editor had paid compliment of holding back the week's issue until it be included When Morland returned to London the Marne and called at the old *Lancet* office at the co of Bedford Street and the Strand, Sprigge wa difficulties because Gerald Horner, then *assistant ed* was serving in the R.A M C, so he said to Mo "why not stay and help?" And Morland sta for 29 years

At this point one might follow the precedent of Hebrew biographer who referring his readers to the of the Chronicles of the King Israel and Judah But though bound volumes of *The La* since 1915 contain most of acts of Morland, and would been very different without what he did himself is inextrica mingled with what other peo did In an effort to analyse influence it has been truly that he found the journal hum but left it human, but perh his greatest effect on our colu was one of refreshment He this effect because he was *artist* and (to the end of unexpectedly long life) a petually surprising person

The artist enables people to familiar things anew, and land had just this faculty angle of vision always seemed be a little different, and, th *this often embarrassed and* s times alienated his acquainta it helped him to be not only an animating journ but an exceptionally valuable member of our profess for to look at things at a new angle is often hig instructive He also had the catholic curiosity of investigator and was ready to be thrilled by any fr thought or fact—though he might lose interest quickly When he wanted to do so, he could absorb body of knowledge very thoroughly, and he rememb a great deal about a great many diverse subjects, fr mathematics to midwives, from infant feeding to European flora, but he had little intellectual taste generalisation, and tended to look at one thing at a ti "on its merits" Hence, as an artist, he preferred small canvas to the large one, and he enjoyed paint detail But whether the canvas was large or small, would avoid monotony by an engaging touch inconsequence in the composition

If this is not the portrait of a creative thinker, it nevertheless the portrait of a born journalist, born make others think Moreover, in this delicate and of exhausted man—the "old poitrinaire" as he cal himself—the mental liveliness was matched and ma profitable by an astonishing capacity for work, day day out, year in year out Skimming, as it seem through the millions of words that poured into th office, he could quickly detect what was new and intere

Morland, when he wanted, could write so catalytic a letter as to draw a contribution from the most unreactive of experts, and even his routine communications were carefully written in a personal way—often in fact by hand But it cannot be said that even through the post he wholly satisfied everybody, for ordinary people often prefer ordinary letters, and few besides harassed editors know how correspondence may improve if allowed to "mature" Those who went to *The Lancet* oracle with a question must be prepared for an oracular reply, which left the "onus" (to use another of Morland's favourite words) on the person receiving it The following, for example, is his answer to a long letter from a doctor who wanted to know about the copyright regulations governing the reproduction of *Lancet* material in foreign broadcasts

Dear L,

I am glad to hear you are helping the British Council to let South Americans know what British medicine is doing We do our own bit too I don't feel I can give you any general guidance on copyright in the air But you would find the Golden Rule applicable and between ourselves the Hippocratic Oath is binding

With kind regards, Sincerely Yours,

EGBERT MORLAND

Copyright was one of the subjects that did not interest him

Even his colleagues seldom had their questions answered directly or comprehensively But when his mental processes seemed to be at their most devious and detached the probable reason was that he was not yet ready with his decision, which he would give in his own time and his own way It was partly because he was so puzzling that he was so fine a teacher, and, whether amusing or infuriating, his enigmatic instructions somehow extracted from his juniors the same kind of effort that he himself put into *The Lancet*

Nor did this taste for the oracular prevent his being energetically practical in other fields when something within his compass needed to be done Hence in his spare time (which did not exist) he did solid work in many useful causes, and in various ways he was of service to the Queen Alexandra Sanatorium at Davos, to the Enham (now Enham Alamein) Village Centre for Disabled Ex Servicemen, to the Medical Defence Union, to the Society for the Relief of Widows and Orphans of Medical Men, and to Sibford School, of which he was a governor But, though a good speaker, he seldom appeared on platforms or at the meetings or dinners of medical societies Disliking public occasions, he was inclined to think that an editor should be a back-room boy, neither seen nor heard except through his journal, and invisible especially to callers None the less he was a sociable person, and never more happy perhaps than in the Athenaeum, which likes a proportion of its members to have their eccentricities He was happy, too, in the fellowships conferred on him by the Royal College of Surgeons in 1936 and the Royal College of Physicians in 1941, though both colleges probably wanted to withdraw their honours when they saw that he described himself (whether to save space or out of modesty) as FRCP&S

When Morland succeeded to the editorship in 1937 he was already 62, and two years later, when war broke out and the decision was reached to move the journal out of London, he was tempted to resign his sisyphean task But, as it turned out, the move to Aylesbury proved a tonic Settled cosily in a flat above the tiny office in Temple Street, he abandoned even the convention of office hours and did most of his downstairs work after supper when his juniors had gone home Freed from the social obligations of his chair, and disguised from former friends by a beard and a dilapidated mackintosh, he took an eager interest in the war-time life of the small market town, and spent more of his time in reflection and reading—though even now he never finished a preferring the random sample With a senior's less of inhibitions, he was finding it easier to show abundant kindness of heart and concern for oth but to keep the balance he showed also more of sharpness of his tongue When directed towards rather than individuals, this asperity was gre enjoyed, and it is pleasant to find in our files his de comment on a rather pompous declaration in distinguished signatories defended the rights and of the citizen Underneath, in his small, neat, decor hand, Morland has written

* I'd rather be in prison with my friends th
free with that lot. Ed. L.

It was sad, in a way, that he should not take com of his journal until his most active years were for he never got full credit for his achievements, these were different from what they might otherwise been But possibly *The Lancet* did not lose the for in his more impetuous moments he often nee someone to tell him to think again Moreover, tho he could rule both by love and by fear, he was not a commander he was a prophet or priest rather th king—an impish prophet but in direct line from the Testament During the war he was already an old with the defects of his high qualities becoming apparent, and it was inevitable that in his cour Aylesbury the executive responsibility should dev more and more on his lieutenants—as once it devolved from Sprigge to him So the honou burden was partly transferred to younger shoulders, when *The Lancet* returned in 1944 to London Mor retired into private life—with a characteristic valedic greeting to his readers

At first at Aylesbury, and afterwards in an old house beside the ancient Friends' meeting hous Wooldale in Yorkshire, he adjusted himself yet aga new circumstances He had given much thought to age—its disabilities and possibilities—and had been one of the first to see the need for a con movement for old people's welfare, comparable complementary to the movement for infant welfare developed during and after the previous world war 1945 he expressed his ideas in a charmingly Morlan pamphlet called *Putting Them on the Map*, written Buckinghamshire committee of which he was instiga member "We must search out the old people in hidey-holes," he said, "and find for ourselves whe they are content with their lot, whether it is a lot which they should be content, and if not what we sh do to amend it" Himself, he well understood the of continuing to be active, and as lately as 1951 he w the biography of a pioneer midwife, entitled *Alice and Stork* He had the advantage of being one of those wh pleasures are of the mind, and for some years of retirement he was also fortunate in his keen enjoym of gardening and walking, and in the companionship his wife But each in turn was taken from him, eventually almost all the power of sight By refinement of age, and its distresses, his face bec less that of a prophet than a saint—a rôle to which had never aspired One of his chief hopes, he said that he might continue to amuse those around him.

He died at York on April 26, in his 81st year, even to the last his mind, though wayward, reta the ardent quality that so often made him seem youngest, though maybe also the oldest, of his comp Throughout his life he belonged to the present and future rather than the past, and many who knew as well as many who did not, have cause to be grat for his disturbing, enlivening, and enlightening spirit

WILLIAM BURRIDGE

D.M. Oxfd

Dr William Burridge formerly professor of physiology l principal of the King George's Medical College and n of the faculty of medicine at Lucknow University d in hospital at Dartford, Kent, on April 21, at the of 69 He was the author of *Excitability a Cardiac dy* (1932) *A New Physiology of Sensation* (1932) *New Physiological Psychology* (1933) and many short les in various journals.

T B writes 'Like his fellow Cornishman mphry Davy, and his pupil Faraday Dr Burridge de important discoveries through brilliantly original eriments using very cheap and simple apparatus book *Excitability* describing his experiments on frog's heart is a medical classic, and this study the beating heart's responses to stimulation enabled to correlate similarities in nervous action and con ous sensation to deduce rhythmical activity in brain l spinal cord neurones and in sensory end-organs and elaborate many logical consequences of assuming ythm in neurones. The fact of rhythm in cerebral rones has since been independently confirmed by er workers some of his predictions remain to be ved by experiment.

"So far Dr Burridge's work has not received the eral acclaim it deserves. We owe to him the new d revolutionary concept of responsiveness as distinct m excitability, a new method of research in pharma ogy, giving new and surprising information on the ltiple actions of some drugs and their quite different ects in large and small doses and a new physiological chology harmonising experiment, sensuous experience d deductive reason and well in advance of any previous ory of sensation and of thinking process.

His own explanation of the opposition that his work d theories met was the power of an orthodox primary umption to blind fully organised minds to any new th that contradicted teaching elaborated from the mary falsely generalised preconception His Puck ing the Doctors (*Medicus* December 1952) gives a l statement of his defence and repays reading

PATRICK KERR DIXON

M.D Dubl. F.R.C.S.I

Dr Patrick Dixon who died on April 21 at Lusaka rthern Rhodesia, had spent nearly thirty strenuous and enturous years as a medical missionary in the Belgian ngo.

e was born in 1898, the son of the late Andrew on, professor of anatomy and dean of the school of ic at Trinity College Dublin Patrick's studies Trinity College were interrupted by the 1914–18 and he was mentioned in despatches for services h the Royal Garrison Artillery in France In 1918 returned to Dublin to graduate in 1922 in science, h first-class honours in mathematics and experimental ence. Two years later he graduated M.B with honours. In 1926 he joined the Garenganze Evangelical Mission the Belgian Congo

For the next twenty five years, despite the effects of ere injuries sustained when he was mauled by a lion, he ved the people of the Luapula Valley with devotion the course of his work he saw the suffering caused by choma and in 1929 he visited India to study this ease under Sir Henry Holland. His published work ls with his experience of its treatment in Central Africa. e hospital which he founded at Chibambo became a ntre for the treatment of eye diseases. In recognition of services he was decorated by the King of the Belgians. In 1952 ill health forced him to leave the Luapula alley, and for a time he was medical officer at Nkana he In 1953 he joined the staff of the Government frican Hospital at Lusaka He also taught at the frican Medical School

A colleague writes: 'Pat Dixon was an eager tireless l devoted worker, content to make do with the most agre equipment yet keeping himself up to date in the dical world and always looking forward In this he as a true disciple of the great Dr Livingstone who had rsed the same country fifty years before Like him o, Dixon bore to his dying day the marks of the lion's unch in his left humerus. He will long be remembered on the divide between Congo and the Zambezi watersheds'

His first wife, Miss Olive Arthur died in 1927 In 1934 he married Miss I H Russell who survives him with a *daughter of his second marriage*

KENNETH BENSON BELLWOOD

O.B.E., B.A, M.B Camb., F.R.C.S.

Dr Bellwood consultant surgeon to the ear nose and throat department of Bedford General Hospital, died at his home on April 17 at the age of 64

He was born in Middlesbrough and was educated at Coatham School, Redcar He was a scholar of Pembroke College, Cambridge, where he took the natural sciences tripos in 1912, and a Shuter scholar at St. Bartholomew's Hospital qualifying in 1914 During the 1914–18 war he was appointed O.B.E. for outstanding service in the Royal Navy In 1917 he took his M.B Soon after he returned to civilian work he entered general practice in partnership with the late W H Miller in Bedford and also specialised in diseases of the ear, nose, and throat. In 1921 he obtained the F.R.C.S. When in 1930 he was appointed E.N.T surgeon to the Bedford County Hospital he laid the foundation of the present successful large and busy E.N.T department at the Bedford General Hospital Despite ill health which first showed itself in 1940, he worked indefatigably, and he was appointed consultant surgeon to the department when the hospital was taken over by the National Health Service in 1948

G A M writes: 'Dr Bellwood as he is called by all in Bedford was loved for his quiet modesty and great kindness to all his patients The greatest sorrow will be felt by the patients he looked after as a general practitioner He loved the hills, and was a great walker in his day Even when he could no longer climb he always went north to his beloved Yorkshire for his holidays'

In 1921 Dr Bellwood married Florence Violet Cooper, who survives him with two daughters

---

Notes and News

HEALTH EDUCATION

At the seminar for public health workers organised by the Central Council for Health Education of Great Britain and held in London from April 19 to 23, delegates attended from 21 countries Dr W Emrys Davies, education officer to the council, said that people do not listen to instruction unless they feel that the subject matter is relevant to their own problems and way of life Hence the first task of the health educator is to assess the basic human needs common to all, in any country, whatever the conditions or climate The second is to establish an atmosphere in which discussion can flourish, and experiments have shown that the discussion group can achieve what its members could not achieve singly The group leader is therefore a more effective person than the lecturer talking to an audience and isolated from his hearers by natural barriers of platform position, shyness, and absence of communication of ideas between members of the audience Dr John Burton, medical director of the council, described the use of case histories which command interest from members of a group and which recall to many experiences that can be used as a basis for discussion Mr W Sellers, film adviser to the Colonial Office, said that in dealing with illiterate people one must evolve three dimensional visual aids which come within the range of their everyday experience Diseases have to be classified in relation to their causes and source—e g, insect infections, airborne and water borne diseases In Nigeria a film van has proved a big attraction because people will comprehend a moving picture when the still one makes no impression

UNDERGRADUATE TEACHING IN LONDON

The difficulties of undergraduate teaching hospitals arising from the shift of population from the centre of London are mentioned by Colonel J J Astor, chairman of the board of governors of the Middlesex Hospital, in the hospital's statistical report for 1954 At the Middlesex the bed occupancy rate is over 90%, and the pressure on the outpatient department is as great as ever, but "there is a tendency for clinics and wards to be deprived of various types of case which are valuable for undergraduate teaching Patients suffering from these conditions are now for the most part being treated at hospitals in the peripheral areas, and in consequence medical students of today are not seeing the cross section of illnesses which was available for their predecessors when this was still a residential area" As an interim measure the Middlesex has arranged with the Luton and Dunstable Hospital for some of the patients on that hospital's waiting list, with their consent, to be transferred to the Middlesex for treatment, and this scheme is working well

"THREE MEN"[1]

Miss Jean Evans, a writer who has turned her talent to presenting the case histories of three living men, describes her book in a sub title as "an experiment in the biography of emotion" Johnny Rocco began life as a rejected child who was often delinquent, but who has finally made a precarious social adjustment William Miller, too, was often delinquent till he became blind, he recovered his sight but (perhaps finding the responsibilities of sight too heavy) became delinquent—and blind—again. Martin Beardson is a tormented homosexual She tells their stories with sympathetic insight, but without interpreting the psychological mechanisms at work. It was inevitable that she should select, from the vast quantity of material she has amassed in the course of her long and friendly association with these men, which facts and which letters and conversations to report, but she has a biographer's skill in choosing what is relevant, and the reader is confidently aware that the picture is true, distorted neither by compassion nor censure Prof G W Allport, professor of psychology in Harvard University, notes in an introduction how valuable he has found the book in the teaching of students Because Miss Evans has avoided imposing her own interpretations, students are stirred to ask questions, and hence to discover much about some common forms of mental sickness. "The first requirement in good teaching," as Professor Allport says, "is to excite greedy curiosity" These cases, he finds, do exactly that

University of Liverpool

At a recent examination for the diploma in tropical med and hygiene the following were successful

P B Acharya, A A Akiwumi, S H Bokhari E J M A Jafri Prakong Kecharanantana N H Khan T J Ma J I Maxwell, H Medina P A Y Narayanan, Margaret C Bridget O'Keeffe, A V Rao, J B Roy, G Singh, S

Dr J B Roy has been awarded the Milne medal in medicine, and Dr J I Maxwell the Warrington Yorke in tropical hygiene

Royal College of Physicians of London

At a comitia held on April 28, with Sir Russell Brain, president, in the chair, the following were elected to fellowship

J F LANDRETH Christchurch New Zealand, J L FRA London J H HALLIDAY, Sydney, R I MACDONALD, To F E PILKINGTON, South Brent, Devon, R L WAT London, A C STEVENSON, Belfast, H A TREBLE, Cant J C RICHARDSON Toronto, J F LOUTIT, Harwell, T E Newcastle upon Tyne, R B KERR, Vancouver, R N TATT Leeds, A C DORNHORST London, W S SUTTON Live B G PARSONS SMITH, London F H SCADDING, London, A LEIGH London, H V MORGAN Khartoum, L D W S Glasgow, D A WILLIAMS, Cardiff, C F HAWKINS Birmin R D TONKIN, London, H P WILLIAMS Coventry, A WILLIAMS Kampala, J R ELLIS London R A JONES Cambs, E K CRUICKSHANK, St. Andrew, Jamaica, G MACDONALD, London, B G MAEGRAITH, Liverpool, W KARUNARATNE, Colombo

The following were elected to the fellowship under by 39b, which provides for the election of non members "w have distinguished themselves in any branch of the sc or practice of medicine"

I DE B DALY F R.S, Cambridge, K G V NYLIN, Stock W G PENFIELD, O M, F R S, Montreal, G F STRONG Vanco

The following, having satisfied the censors' board, elected to the membership

stitute of Cardiology, London

Dr. Lawson McDonald has been appointed assistant rector of the institute

Dr McDonald who is a graduate of the University of Cambridge lified from the Middlesex Hospital London, in 1942 After ding house-appointments there he served in the R.N.V.R. m 1943 to 1946 From 1946 to 1948 he held various appoint nts at the National Heart Hospital and the Institute of Cardio y. In 1948 he returned to the Middlesex Hospital as medical strar and in 1949 took the M.R.C.P Later he was appointed stant to the professor of medicine at the Middlesex Hospital, d visited Stockholm in connection with research into peripheral cular disorders He graduated M.D in 1952 He was awarded Rockefeller travelling fellowship for 1952–53 and during its tenure worked in Boston His publications include papers on peripheral cular disease ischæmic heart disease and mitral valve disease th special reference to the pulmonary circulation and to surgery the mitral valve

mmonwealth Health and Tuberculosis Conference

Mr Iain Macleod the Minister of Health will open this nference at the Royal Festival Hall London, on June 21 ther speakers will include Dr Johannes Holm (W.H.O) r P V Benjamin (India) Prof Etienne Bernard (France) r Walsh McDermott (U.S.A) Dr E Ross (Canada) r H G Trimble (U.S.A) Prof Arvid Wallgren (Sweden) r Geoffrey Marshall Dr George Day and Dr Honor Smith. urther particulars may be had from the National Association r the Prevention of Tuberculosis, Tavistock House North ondon, W.C 1

eview of Byssinosis Benefit

The Minister of Pensions and National Insurance has ked the Industrial Injuries Advisory Council to review the rovision made for byssinosis under the National Insurance Industrial Injuries) Acts. This review is being undertaken r the council by their industrial diseases subcommittee The chairman of the subcommittee is Sir Arnold Plant and e members include Prof R E. Lane F.R.C.P

Regulations made under the Industrial Injuries Acts at present rovide insurance cover against the disease for people who have een employed at some time since July 5 1948 and for at least wenty years in all, "in any occupation in any room where any rocess up to and including the carding process is performed in actories in which the spinning or manipulation of raw or waste tton is carried on." Benefit is not however, available unless the erson concerned has died from byssinosis or his disablement from e disease is assessed at not less than 50% and is likely to be ermanent These conditions were imposed because of the difficulty f distinguishing byssinosis from bronchitis and emphysema of non-occupational origin.

Persons and organisations are invited to submit written vidence to the secretary of the council 10 John Adam Street London W C.2 not later than June 6

Institute of Hospital Administrators

The annual conference of this institute will be held at Caxton Hall Westminster S W 1 from May 12 to 14 The principal subject chosen for discussion is Group Administration.

British Association of Physical Medicine

At a meeting held on April 23 the following officers were elected for 1955–56 :

President Lord Horder vice president Dr W S Tegner; hon. treasurer Dr A C. Boyle hon secretary Dr G O Storey; hon editor Dr H A Burt

The Medical Sickness Society

On April 26 a reception was held by the Medical Sickness Annuity and Life Assurance Society Ltd. to mark the opening of their new offices at 8 Cavendish Square London, W 1 The guests were received by the chairman, Mr R. McNeill Love

Royal Statistical Society

Study Circle on Medical Statistics—The annual general meeting of this circle will be held on Tuesday May 31, at 5 45 P.M. at the Westminster Medical School, Horseferry Road S W 1 Afterwards Dr P Armitage Dr John Knowelden, and Dr R F Wrighton will read short papers on Controlled Trials in Medical Research

Shortage of Dentists

The Interdepartmental committee under the chairmanship of Sir Arnold McNair, which has been set up by the Minister of Health and the Secretary of State for Scotland to ascertain the reasons for the lack of candidates for training as dentists, has held its first meeting and is ready to receive evidence Persons or organisations wishing to give evidence should in the first instance communicate in writing with the secretary of the committee, Mr T C. L. Nicole at the Ministry of Health Savile Row London, W 1

Food Hygiene Advisory Council

On May 2 Mr Heathcoat Amory the Minister of Agriculture Fisheries and Food announced that 11 members of this council are to represent the public 3 the trades, and 3 the workers in the trades. Lord Strong is to be chairman and other members include Mr S W Barnes, secretary to the governors of King's College Hospital Sir Harry Sinderson, F.R.C.P.E director for Sussex of the St John Ambulance Association, and Mrs. James Tweed, chairman of the house committee of St James's Hospital Balham.

Dr Stott Commemoration Fund

This fund has been started as a tribute to the work of Dr L B Stott who until his retirement owing to ill health last December spent 33 years as medical officer at Papworth Village Settlement. In view of his interest in children it is proposed to use the fund for prizes or grants for children at Papworth Village or school and/or a shelter in their playing field

Contributions should be sent to F E Redman secretary of the fund St Peter's Hostel Papworth Everard Cambridge

Hæmophilia Society

The annual general meeting of this society on April 24 was attended by 60 members and a number of doctors interested in hæmophilia Sir Lionel Whitby F.R.C.P was re-elected president and Dr R G Macfarlane was invited to become a vice president Reports on the work of groups in the South of Scotland Manchester Newcastle Sussex and Middlesex were received During the past year the society had sponsored the formation of similar societies in Australia France Holland, and Switzerland. Its address is 94 Southwark Bridge Road London, S E.1

Hospitals in Eire

The second of three sanatoria which the government of Eire is building was opened at Blanchardstown co Dublin by Mr T F O Higgins, the minister of health on April 22 The west regional sanatorium at Merlin Park Galway was opened in 1952 and the southern regional sanatorium will be opened next month The hospital at Blanchardstown will be known as the James Connolly Memorial Regional Sanatorium It has cost £$1^1/_4$ million, and it will accommodate 520 patients

It is laid out in seven 40 bed pulmonary blocks a 40 bed isolation and infective children's block four 30-bed non-pulmonary blocks (including orthopædic) and a three-storey hospital and treatment centre with operating theatres and X ray and physiotherapy departments with 80 beds The group of buildings on the 240-acre site also includes a nurses home for 100 nurses and houses and flats for the medical staff

International Society of Criminology

The third congress of this society will be held at Bedford College, London, from Sept 12 to 18, under the presidency of Dr Denis Carroll Further details may be had from the organising secretary, Mr H O Cox, 28, Weymouth Street, W 1

Indian Medical Services Dinner Club

The annual dinner of this club will be held at the East India and Sports Club Ltd , St James's Square, London, S W 1, on Friday, June 10, at 7 30 P M Tickets may be had from the secretary of the club, Medical Board Room, Commonwealth Relations Office, Matthew Parker Street, S W 1

Food Microbiology and Public Health

During its summer conference and annual meeting in Cambridge the Society for Applied Bacteriology will hold a symposium on this subject on July 4 and 5 This is open to non members, and further particulars may be had from Mr G Sykes, the hon secretary, Boots Pure Drug Co , Ltd , Microbiology Division, Nottingham

Kashmir Medical Congress

Arrangements are being made for a party from this country to attend a medical congress in Kashmir next November The approximate cost of £298 per person will include return air fare from London and travelling and living expenses in India Further details may be had from Dr R U Hingorani, 128, Harley Street, London, W 1

International Association of Gerontology

The fourth congress of this association will be held in It early in September, 1957

Vitamin E Congress

This international congress will be held in Venice Sept 5 to 8 at the Cini Foundation on the Island of Giorgio Maggiore Further details may be had from secretary, Prof Emilio Raverdino, Via Pietro Verri 4, Mi

National Insurance Benefits Abroad

People otherwise entitled to National Insurance retirem pensions, widows' benefits, or guardian's allowance will able to draw their benefit in any country in the world if d regulations submitted to the National Insurance Advis Committee are approved At present these benefits be paid to people resident abroad only if they are living in Commonwealth or in the Republic of Ireland

---

The British Standards Institution have published a new stand (B S 2606) specifying requirements for flexible lead rubber g for X ray workers Copies of this standard may be obtained f the institution's sales branch, 2, Park Street, London, W 1, p 2*s* 6*d*

CORRIGENDUM *Hydrocortisone in Lesions of Soft Tissue*—In article by Dr Crisp and Dr Hume Kendall (March 5) the for of hydrocortisone was wrongly given The positions of the -O and - CO CH₂OH groups attached to the 17 carbon atom sh be reversed

GICAL MEDICINE UNIVERSITY COLLEGE HOSPITAL, LONDON

om the South East Metropolitan Regional Neurosurgical Centre

In the latter part of 1949 working with Dr Ström sen at the Runwell Hospital, one of us (G C K) was le to introduce to this country the operation of orbital dercutting devised by Scoville in 1948 In 10 patients o had not benefited from leucotomy the operation ve results which in Dr Ström Olsen s opinion, justified extension to cases of neurotic tension in which Scoville d claimed success

During 1950 orbital leucotomy was used in association th Dr Ström Olsen and Dr Bierer and since 1951 ore than 50 such cases have been operated on at the uth East Metropolitan Regional Neurosurgical Centre the Brook Hospital Blackheath Elsewhere other difications of the original leucotomy have been per med, and Sargant (1953) has drawn attention to their ue He recommended their use in "intractable ychosomatic states in anxiety hysteria and in anxiety d depressive states in obsessional personalities " and pointed out that other forms of treatment notably chotherapy might succeed after operation though y had failed before.

The results obtained by our modified orbital operation peared so encouraging as to warrant a closer analysis the patients psychological condition and we have refore collaborated in this interim report The only vious English survey of orbital leucotomy is that of and Lewin (1953) of 20 cases operated on chiefly the late Sir Hugh Cairns at Oxford

Our review covers a consecutive series of 59 patients rred by various psychiatrists, usually because they such anxiety or depression that life was a misery being asked by letter to attend for follow up 4 did not ly and remain untraced 3 others had undergone cotomy previously and were therefore excluded from survey Of the remaining 52 40 were British and Polish and all save 4 had been ill for more than two rs—several of them for more than ten years

Basis of Surgical Treatment of Mental Disorder

(G C K)

The surgical treatment of mental disorder began with e injection of alcohol into the frontal lobes and has dually developed into localised anatomico physio ical investigation yielding fresh information about the chanisms of emotion and the intellectual activities the frontal regions. Our knowledge of these matters mains imperfect and the investigation continues.

The effects of the full standard leucotomy dividing central core of white matter within the frontal lobe wed that it was preferable to limit a leucotomy incision the lower segment particularly to the lower and ier fibres within the frontal lobe so as to maintain the cessary reduction in emotional tone while minimising associated intellectual deficit

Precise electrocoagulation of the dorsomedial nucleus the thalamus (Spiegel and Wycis 1949) has shown that all the effects of leucotomy may be produced by a lesion strictly localised to one area of the brain from which the afferent connections proceed to the frontal cortex

Our knowledge has been increased by experiments on individual projection pathways either by excision of limited cortical areas (cingulate superior convexity and orbital) by topectomy, and by undercutting similar areas leaving the cortex intact but severing the afferent and efferent fibres passing to and from the selected zones All these methods are intended to modify emotional behaviour while minimising concomitant damage to personality and intellect

Many of these later modifications of technique were developed because of our appreciation of the importance *of the thalamocortical connections.* Le Gros Clark and Boggon (1933) and Le Gros Clark (1948) have shown that a large part of the frontal cortex is an afferent projection area for the dorsomedial nucleus of the thalamus, comparable with the projection areas of the visual and auditory areas of the cortex, there being a well-defined point to point projection of fibres in which the anteroposterior axis of the dorsomedial nucleus projects in serial order on to the anteroposterior axis of the frontal lobe, to the cingulate superior convexity and orbital surfaces Since the dorsomedial nucleus of the thalamus is essentially a relay station for the transmission of impulses originating in the hypothalamus, the frontal cortex seems to act in part at least as the projection area for fibres concerned with hypothalamic activity and of obvious importance in emotional integration The later developments of surgical technique have concentrated on interrupting certain of these connections alone while leaving the remainder of the frontal cortex undisturbed

Preceding accompanying and giving impetus to these surgical assaults there has been a gradual change in our conception of the nature of intellectual and emotional activity No longer is intellectual function regarded as purely cognitive dependent upon the perfect function of the cerebral cortex working in isolation, and independent of any influence ascending from the basal areas of the hippocampus and hypothalamus, which are concerned in autonomic and emotional activity in the affective sphere It has come to be realised that the function of the cortex may be profoundly disturbed by stimuli ascending from the basal areas of the brain

> Dana (1921) and Cannon (1927) suggested that emotion resulted from the action and reaction of the diencephalon and the cerebral cortex the diencephalon, having received sensory impulses associated with emotion would discharge upwards to the cerebral cortex impulses which gave rise to emotional experience or subjective feeling at the same time as it would discharge downwards the motor impulses which produced emotional behaviour
>
> Nathan (1931) held that emotion and personality were localised in the region of the third ventricle and traced the development of this theory from the work of earlier observers.
>
> Alford (1933) thought that emotion and consciousness were particularly disturbed by basal lesions in the left cerebral hemisphere

Papez (1937) pointed to the ensemble formed by the hypothalamus gyrus cinguli, hippocampus and their various connections, and regarded these as the probable anatomical substratum of the emotions. In elaborating this theory he displayed the wide connections that exist between the thalamus hippocampus and hypothalamus and between the thalamus gyrus cinguli, and frontal cortex In discussing the hippocampus he pointed to the absence of evidence of olfactory function in this area, and drew attention to the facts that in rabies the Negri bodies are most abundant in the large ganglion cells of the hippocampus, and the patient shows intense emotion and hyperæsthesia to all forms of stimuli with the result that all stimuli provoke fear sometimes mingled with rage

In Papez's view somatic (including visceral) impulses entering the circuits of these basal areas may obtain emotional colour and finally reach the cortical level as "a stream of feeling" modifying the function of the cortical regions This theory suggests that the pathways connecting the thalamus to the orbital cortex and other regions of the frontal lobe contain the afferent projection systems for emotion, and it is noteworthy that each of the cortical areas receiving such pathways gives rise to efferent fibres passing towards the hypothalamus which could constitute the pathways for emotional reaction As Le Gros Clark (1952) has stated

> "It has come to be realised that intellectual and emotional processes are so intimately interlocked in any form of mental activity that *it is not possible to separate them even as* arbitrary categories Intellectual processes are only capable of normal expression if they are activated and directed by the driving power of emotional processes, The cerebral cortex *may be structurally intact but its function can be grossly* deranged if it is thrown out of gear with those more primitive parts of the brain which provide neural bases of emotional reaction"

In extending the surgical treatment of mental disorder to the sphere of the neurotic and psychoneurotic it is to the relief of an abnormal emotional charge disturbing the function of intelligence that the treatment appears to be most directly applied We seek a method which will produce the greatest modification of emotional tension without associated injury to intellectual pathways

Scoville (1949) has described the techniques for undercutting each of the three cortical areas—cingulate, superior convexity, and orbital—to which fibres radiate from the thalamus That the orbital technique is the most likely to lower neurotic tension without causing a serious intellectual deficit is suggested by the observations of Rylander (1939) which indicate that lesions of either the orbital or the inferior aspect of the frontal lobes produce changes in emotional tone rather than in intellectual or psychomotor activity Rylander (1952) in particular has shown by psychometric studies that lesions on the superolateral aspect of the frontal lobe are more likely to produce intellectual disturbances Experimental evidence also shows that stimulation of the orbital areas produces autonomic responses, and ablation of those areas tranquillity or loss of fear

Scoville's techniques were fully described and illustrated at the International Congress of Psychosurgery held at Lisbon in 1948, and subsequently published (Scoville 1949) Scoville states that he aims to undercut the entire orbital surface, including the prechiasmatic area, *isolating the entire cortex* over the orbital plate as far back as the level of the anterior clinoid process on the inner side, and as far laterally as the junction of grey and white matter on the lateral aspects of the lobe We have deliberately modified this method, omitting the lateral portion of the cut and confining the incision to a narrow arc about 2 5 cm wide passing back on the inner aspect of the lobe to a point directly beneath the anter horn of the ventricle at a depth of 5 5–6 0 cm from t frontal pole (fig 1) This modification was introdu to produce further evidence of the importance of t ventromesial fibres within the frontal lobe and to av damage to the hippocampal relays in the lateral portio of the lobe

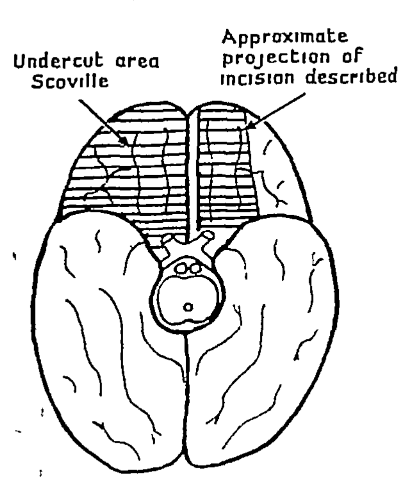

Fig 1—Approximate site and extent of incision in Scoville's (1949) undercutting operation and com[illegible] those of incision used in present

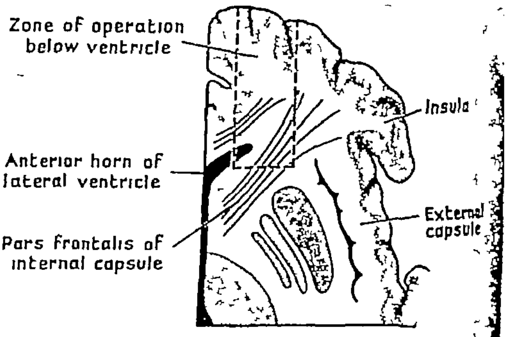
Electrocoagulation within the dorsomedial nucleu the thalamus (Spiegel et al 1947) produced benefic effects chiefly in the emotional sphere These res are by no means solely *attributable to the connect* between the dorsomedial nucleus and the frontal p jection areas (probably hypothalamic connections involved as well), but they do indicate that any signific fibres concerned in emotion and passing to the orb cortex must arise from the inner and lower area of lobe and hence could be divided close to their origin that point

Le Gros Clark (1948), discussing the afferent pathw from the thalamus, states that projection is well def between certain groups of cells in the dorsomedial nucl *and the frontal cortex, fibres proceeding to cortical* ar 8–12 approximately in order from the caudolateral part of th *dorsomedial nucleus to the anteromedial part of the* cort

Meyer et al (1947) concluded that it is the pars ma cellularis *of the nucleus that projects on* to areas 11 and in the orbital frontal cortex All the fibres projected to th orbital cortex spread thereto from the posteromedial asp of the lobe, and it is this area that has to be cut at the *of concentration* of the fibres below the pars frontalis of internal capsule rather than the outlying parts of the matter towards the inferior frontal convolution (fig 2)



Zone of operation below ventricle
Insula
Anterior horn of lateral ventricle
External capsule
Pars frontalis of internal capsule

Fig 2—Transverse section through right frontal lobe seen from ***Interrupted line shows zone of operation lying at deeper le ventricle.***

Lesions in the lateral aspect of the inferior surface of *frontal* lobes may interrupt fibres passing to the tem pole and hippocampus Efferent association tracts arise area 47 of the frontal lobe (area orbitalis agranularis) running as the uncinate fasciculus, pass lateral to the ext capsule and radiate to area 38 in the pole of the temp lobe Degeneration has been observed near to or in this fasc by Meyer et al (1947) in post-leucotomy specimens T fibres form part of a hippocampal circuit involving hip campus, fornix, hypothalamus, thalamus, *orbital* co uncinate fasciculus, temporal pole, temporo ammonic tr hippocampus, less well recognised than the well known cir hippocampus, fornix, mamillary body, thalamus, gyrus ci hippocampus Positive evidence on the function of th circuits is lacking

It has been suggested that neuronal activity could maintained in a steady state between these circuits e long periods, forming a reservoir or background for emoti expression Certainly bilateral disturbance of *these* cir seems to be undesirable

Klüver and Bucy (1939) reported changes in emoti behaviour in monkeys after excision of the temporal lo Hypersexuality has been observed after *bilateral* div these circuits Serious results have followed ablation of posterior orbital *regions in* monkeys (Ward and McCu 1947) with loss of social conscience

Hence, although it has been suggested that tion of the uncinate fasciculus is more importan refrontal leu otomy than sec on of the thalmocortical fibres, xcept where the im is relief of sceral pain, we emained unconvinced of the dvisability of this ep and decided eliberately to void these lateral nd posterior pects of the lobe nd so to avoid he possibility of ntroducing undeirable character hanges which ave sometimes en observed in e case of penetrating wounds in at area of the rain

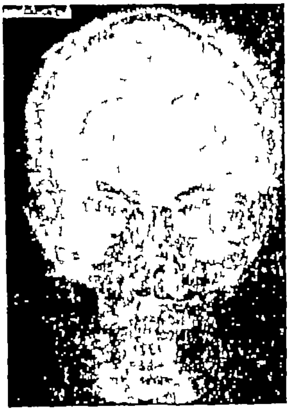


Fig 3—Position of trephine circles for orbital leucotomy

Operation

(G C K)

A transverse scalp incision concealed within the hair e is used the anterior flap being reflected forwards to pose the frontal bones as far down as the level of e orbital margins. A flap of pericranium corresponding to the exposed area is similarly reflected for ards after mobilisation of the fascia from the line of the mporal crest on each side thus exposing the frontal nes Bilateral trephined circles 3 75 cm in diameter e now fashioned at a point above the level of the frontal nuses and extending to within 1 cm of the midline on ch side (fig 3) The bone-dust thus formed is collected r later use The exposed dura is incised transversely the lower third of the exposed area (fig 4) and stay tures are inserted The frontal pole is raised from the or of the anterior fossa to determine the level of the terior clinoid process and a transverse incision 2 5 cm. le is made in the cortex hæmostasis is secured and e incision is deepened to the white matter Spatula rceps are inserted into the cortical incision and the hite matter is gradually divided with a fine suction be at the junction of grey and white matter above the bital plate on each side the incision being kept parallel the orbital roof as far back as the level of the tip of e ventricle the spatula blades being used as retractors. ould the tip of the ventricle appear in the line of the cision it is raised with the upper blade of the spatula, nd the incision is deepened to a total depth of 5 5–6 0 m beneath the ventricular tip at which level it is idened transversely to 3 0–3 5 cm The incision is actically bloodless, but occasionally bleeding points are seen towards the inner aspect of the incision near the grey matter the bleeding is easily arrested by pressure or by electrocoagulation The dura is now closed with silk sutures and the bone discs are replaced and moulded into position with a paste made from the bone dust The pericranium is brought back into position over the bone discs to conceal any minor surface irregularity, and the wound is sutured in layers

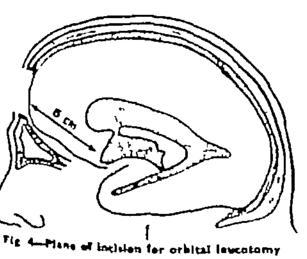

Fig 4—Plane of incision for orbital leucotomy

The postoperative course is smoother than that of a patient who has undergone major leucotomy Incontinence is hardly ever observed There is always a period of drowsiness for the first twenty four hours, and occasionally confusion for the first two or three days, but most patients are fully oriented on the day following operation Within four or five days they can be allowed out of bed, by which time the relief of tension is already apparent The mortality of this operation is obviously low so far more than 75 consecutive operations have been performed without any death

Psychiatric Survey

(R F T)

The survey included: (1) cases seen by me only after operation, and (2) cases seen before and after operation

1 Previous records were studied in detail and compared with the patients present state Since usually no formal or comparable assessment had been made by the psychiatrist who originally referred them it was not easy to be sure that comparisons were reliable; but, to get as much uniformity as possible the tables of symptoms prepared (see below) were sent back to all these psychiatrists for their comments. In most cases, but not all the psychiatrists had seen their own patients again after operation.

2 These patients were seen immediately before the operation, soon after it and some weeks after it The changes were naturally easier to assess but here also the psychiatrists who had originally referred the patients were asked to comment on the opinions formed Among these patients were 12 Poles who were reviewed in the same way by Dr G Bram of Mabledon Park Owing to language difficulties it was impossible for me to make any adequate assessment in these cases but the criteria had been agreed with Dr Bram

TABLE I—EFFECT OF OPERATION ON SYMPTOMS

Symptom	No of patients with symptoms before operation	Results after operation			
		Much better	Better	Unchanged	Worse
Depression	3[illegible]	[illegible]	8	2	
Anxiety	37	19	11	3	1
Severe insomnia	8	4	4		
Headache	8	[illegible]	5	1	
"Blackouts"	2	2			
Gross lack of confidence	1[illegible]	[illegible]	8		
Lack of interest	18	8	9	1	
Obsessions	13	5	[illegible]	[illegible]	
Phobias	4	2	1	1	
Impaired memory	7	[illegible]			5
Impaired concentration	8	1	4		3
Loss of weight	7	7			
Ideas of reference	6	[illegible]	1	3	

The general results were classified as follows:

A	Markedly improved	23	
B	Some improvement	21	(of whom some are apparently still improving)
C	Unchanged	7	(of whom 3 had shown temporary improvement)
D	Somewhat worse	0	
E	Markedly worse	1	

The various symptoms recorded before operation are listed in table I together with the change after the operation

Besides these symptoms certain others were recorded before operation: rosacea (1), cleared menorrhagia (1) improved; frigidity (3) improved in 2, but persisted in 1 hysteria (3) persisted; palpitations (2) persisted and pruritus (2) cleared up

Table I shows that a great improvement was obtained as regards depression, anxiety and loss of weight many patients' interest in their surroundings was restored, and their confidence re established, and, although most of the patients expressed themselves as having some way to go yet, they had also some confidence that they would go this way The effects on failure of *concentration* and of memory were less good, and these symptoms were in several cases made worse This does not refer to the immediate postoperative period of a week or two, when some impairment of concentration and memory was expected (but passed), *but to several months later* Nevertheless these symptoms did not appear to cause any great anxiety in the patient No deterioration in personality was evident to me or to any referring psychiatrist in any of those in category A, B, or C

RELATION OF PROGNOSIS TO VARIOUS FACTORS

Previous Personality —Table II shows the cases grouped into various personality types and separated according to their grade of improvement The only conclusion which it seems legitimate to draw here is that hysterical personalities, like hysterical symptoms, offer less ground for hope

TABLE II—RELATION OF PERSONALITY TO PROGRESS

Type	No of cases	Category			
		A	B	C	E
Dependent	14	8	5	1	0
Cycloid	4	4	0	0	0
Obsessional	11	2	6	3	0
Hysterical	5	1	2	2	0
Schizoid	13	6	5	1	1
Psychopathic personality	1	0	1	0	0
Not psychopathic	4	2	2	0	0

Ætiology and Diagnosis —The nature and severity of *the psychological factors which had precipitated the* illness were investigated but the onset was so long ago that the history given cannot be very reliable In most cases, however, some emotional stress had either caused or precipitated a breakdown Classification being a matter on which psychiatrists notoriously disagree, the symptoms listed in table II and the diagnoses listed in table III may be regarded here with some reserve The 52 cases had, however, been labelled, under the existing nomenclature, and these have been tabulated against their progress *It was clear that many* cases showed a combination of anxiety with depression, or with obsessional features as table I shows

TABLE III—*RELATION OF DIAGNOSIS TO PROGRESS*

Diagnosis	Category			
	A	B	C	E
Reactive depression	5	5		
Endogenous depression	2			
Anxiety state	8	2	1	
Obsessional state	2	6	3	
Hysteria	1	2	2	
Schizophrenic state	5	5	1	1
Psychopathic personality		1		

Previous Treatment —These patients had mostly been selected, as noted above, because they had not responded permanently to treatment, but some had previously made temporary progress under electroconvulsion therapy (E C T), and it may be of interest to record the relationship here (table IV), for it is sometimes held *that temporary* relief from E C T is an indication for operation It seems fair to conclude that the response to E C T gives no indication of what the response to orbital leucotomy is likely to be

Length of History —So far as the records could be obtained, the grades of recovery were grouped against the d of the illness (table V) Of the category C patients 2 were hysterics, this is at least as likely a rea as the length of history for their lack of improvem Though it appears that marked improvement is m likely in *shorter cases*, *some improvement* may expected from even the longest

TABLE IV—RELATION OF PREVIOUS E C T TO PROGRESS

—	Category			
	A	B	C	E
Previous benefit from E C T	8	7	1	1
No previous benefit from E C T	8	9	3	
Not previously treated with E C T	7	5	3	

Age —The correlation between age and progre given in table VI and does not seem to be significant

NEED FOR SUBSEQUENT PSYCHOTHERAPY

Some of the patients improved so much as to need further treatment, others, notably in categories B a C, made less or temporary improvement and appeared benefit from psychotherapy where it was available. was notable, however, that *some patients relapsed* wh treatment was lacking (for reasons which reflected discredit on anyone), and this point should always considered by the psychiatrist when the patients retu to his care after discharge from hospital.

MAINTENANCE OF IMPROVEMENT

The patients were necessarily seen at different peri after their operation, and observations made on th rate of progress and its maintenance, or of relapse, can readily be analysed The following facts may, how be of interest

TABLE V—RELATION OF DURATION OF ILLNESS TO PROG

Duration (years)	Category			
	A	B	C	E
Up to 5	15	7	2	1
5–10	7	6	1	0
More than 10	1	8	4	0

(1) *Some improvement was recorded in most* pat within three days after the operation, but 1 patient did *improve until seven months afterwards*

(2) This improvement went on steadily for several we in most patients, and for months in some

(3) Several patients benefited from postoperative psy therapy whereas previously they had been inaccessible

(4) Nearly all those seen more than a year after operation had remained well since the end of that *year*

(5) Several patients graded as C (unchanged) had impro but subsequently relapsed

Illustrative Cases

Case 1 —(Reported by Dr JOSHUA BIERER)

A woman, aged 42, when first seen in 1950, complained depression, inability to travel, constant fatigue, dyspe palpitations on effort, pains in various parts of the bo gastric disturbances, loss of appetite and weight, constipat insomnia, suicidal thoughts, and anxiety about illnesses as tuberculosis and insanity She seemed to be under gr emotional strain She answered questions readily b appeared to have difficulty over her memory and concen

TABLE VI—RELATION OF AGE TO PROGRESS

Age (years)	Category			
	A	B	C	E
20–30	5	3		
30–40	3	7	3	
40–50	4	5	2	1
50–60	8	4		
Over 60	3	2	2	

ion. There were however no signs of hallucination, elusions, or feelings of unreality or depersonalisation

Past History.—She had nearly died of pneumonia at the e of 9 and had had a duodenal ulcer while still at school. er appendix was removed at 20

Family History.—Her father died at 55 of cerebral hæmor age, when the patient was aged 17 but the mother lived til 1952 Mother was a very possessive dictatorial woman brother a year older than the patient, to whom she was eatly attached was killed in a motor accident before her arriage

Childhood.—She had always been shy timid and reserved ut quite normal apart from that. She was so shy that she ed to hide the fact that she was using the lavatory Felt eful in her first school but felt happier when she changed r school at the age of 15

Sexual History.—Menstruation started at the age of 17 xual relations with her husband caused pain and horror ding to frigidity Infrequent throughout marriage, and ost ceased after birth of second child

Clinical Assessment.—This patient looked younger than her e; her periods started late and her mother suppressed all evelopment towards independence. The patient sought to nd her independence in her married life but was too immature o take any responsibility *She expected pleasant feelings*, ection, love, and security but instead she experienced rror and insecurity her husband being financially unreliable aving been used to complete dependence and having xpected freedom from what she experienced as slavery she lt cornered. This caused such tension most of the time that en the security of nursing home specialists, and large doses f barbiturates did not bring her any relief Electroplexy nd prolonged narcosis, like any form of psychotherapy ought her only a very temporary relief Life to her her amily and her doctors became unbearable

Progress.—She postponed the operation twice because elations advised her against it in the end she agreed, and rbital leucotomy was performed in May, 1951 She was sent r six weeks convalescence; she hated the place she was nt to the food, and the company She returned to work in r home rather too soon, according to her own statement

Effects.—This emotionally and otherwise immature patient ho showed marked depressive, hysterical and hypo- ondriacal symptoms of long standing who underwent and used others unbearable suffering was completely relieved y the operation and enabled to live a normal life again his was achieved with so little personality change that it d not interfere with her life Two years after the operation he described her state as 'a wonderful feeling' She had no mplaints, except sometimes slight nervous depression. All r tension has gone she can run her house and travel any here (which she could not do before) She enjoys going to the atre though she does not get the same thrill out of it

Case 2.—(Reported by Dr G BRAM)

A woman, aged 40 was admitted to Mabledon Park Hospital n June 27 1951 with delusional ideas of persecution pression and *emotional instability*

History.—Apparently she was in good health until August 44 when she was wounded by a shell splinter in the right rietal occipital region She was unconscious for several urs. For four months after being wounded she had left ded paresis, and later she developed pain in the left shoulder d arm which did not respond to any analgesics.

Course of Illness.—On admission in 1951 she was apathetic nd depressed and expressed delusional ideas of persecution; he said that the pain in her left shoulder and arm was caused y some electric currents used against her by unknown eople Three weeks after admission she refused to eat nd had to be artificially fed She had twelve electroconvul ions with very good response She became symptom free nd the pain in the left shoulder and arm completely subsided. he remained well for five months and then relapsed displaying he same symptoms as before A further course of E C T was iven but without any improvement

Orbital leucotomy was done in October 1952

Effects.—The patient made remarkable progress and was ischarged in full remission four months later (the pain in he arm was no longer present) When she was readmitted for a few days in September 1953 for review it was found that he had fully maintained her remission She can look after rself and do part time work The pain in her left arm had ever returned.

Case 3.—(Reported by Dr M WATSON and R F T)

A woman was first seen in 1952, at the age of 55 She had had depression since June 1949 fluctuating in intensity It had improved somewhat with E C T (but this produced so much panic that it was stopped) and with œstrogens and dexamphetamine but she had always soon relapsed. She had a demanding and sick husband and a daughter with disseminated sclerosis One suicidal attempt Her depression was associated with guilt indecision and feelings of emptiness in her head some paranoid ideas; short occasional hypomanic phases with gross extravagance

Past History.—Subtotal hysterectomy at the age of 42 No menopausal symptoms Left mastectomy at 43 for carcinoma.

Family History and Childhood.—Apparently happy relationships with no relevant incidents. Husband a war pensioner now unreasonable and doing no work Five daughters.

Orbital leucotomy in March, 1952

Effects.—Much improved twenty five days after operation and steady *progress until seen eighteen months later* except for two interludes—a gross obstructive jaundice in July 1952 and a short phase of laziness and aggressiveness in December, 1952 The jaundice was completely painless and a secondary carcinoma was suspected but it cleared up in three weeks and was apparently an infective hepatitis In November 1953 she had no complaints, being cheerful and placid, but not unduly so She was quite rational, coöperative, and capable of coping with the domestic stress which still persisted She regarded the change in herself as wonderful

Conclusions

The criteria used to select these patients had not been carefully defined beforehand, but clearly most of them had severe anxiety or severe depression They had long records of illness and misery (misery which affected their families too) no previous psychotherapy had been of avail E C T had given little relief, and surgery was their last hope In these circumstances a high percentage of success would scarcely be looked for

This being so the success of the operation seems remarkable 23 out of 52 were markedly better, 21 somewhat better and only 7 unchanged Only 1 was worse in general, and though a few had greater difficulty in concentration or memory even these regarded themselves as better and happier A deterioration of personality was recorded in only 1 case

Though no sweeping conclusions can be drawn in an interim report on so small a series, these results suggest that orbital leucotomy should be seriously considered in long-standing severe anxiety states and depressions which do not respond to psychotherapy

It is not yet possible to say which patients will benefit most. Previous response to E C T offers no guide to prognosis nor does age The results seem more hopeful if the duration has been less, as might be expected Cases with hysterical symptoms do not seem to be suitable for the operation

All cases should be reviewed by their original psychiatrist after the operation Some patients need further psychotherapy and will benefit from it even if they did not before

We are much indebted to our neurosurgical colleague Mr G Northcroft for preparing the accompanying diagrams We would like to express our gratitude to all the psychiatrists in this region who recommended patients, supplied information and checked the assessment made later; and in particular we wish to thank Dr Bierer and Dr Bram for more detailed assessment and for permission to publish in detail the findings in cases 1 and 2

UNDERCUTTING OF ORBITAL CORTEX IN CHRONIC NEUROTIC AND PSYCHOTIC TENSION STATES

R Strom-Olsen
M D Wales, B Sc, D P M
PHYSICIAN SUPERINTENDENT

D W C Northfield
M S Lond, F R C S
NEUROSURGEON

RUNWELL HOSPITAL, WICKFORD, ESSEX

The risk of personality defects has deterred many from applying leucotomy in chronic neurotic and other tension states (Strom-Olsen 1946) The patient with a well-preserved personality is likely to show greater loss than one with a simple and shallow personality (Ström-Olsen and Tow 1949), and, though standard leucotomy can be justified for a chronic disturbed psychotic who usually shows much deterioration, it is in our opinion inadvisable for the person with an intractable neurosis A different operation was therefore required for cases of chronic anxiety, obsessional neurosis, and hypochondriasis, and for some cases of paranoid psychosis and chronic depression which do not respond to electroconvulsion therapy (E C T) or other treatment

TABLE I—CATEGORY A

Case no	Diagnosis	Duration of illness before operation (yr)	Length of follow up after operation	Result
1	Chronic anxiety state	5	4 yr	Recovered
2	Chronic hypochondriasis	15	3¼ yr	Recovered
3	Chronic anxiety state	8	2¾ yr	Improved
4	Chronic hypochondriasis	11	2¾ yr	Improved
5	Psychopathic personality and drug addiction	8	2½ yr	Improved
6	Paranoid schizophrenia	5	2 yr	Recovered
7	Chronic hypochondriasis	20	2 yr	Improved
8	Chronic anxiety state	4	2 yr	Recovered
9	Chronic endogenous depression	3½	1¾ yr	Recovered
10	Paraphrenia	5	1¾ yr	Improved
11	Chronic anxiety state and depersonalisation	3½	1 yr	Recovered
12	Chronic melancholia	10	5½ mos	Not improved, died
13	Chronic depression	3	5 mos	Recovered

The method of selective cortical undercutting devised by Scoville (1949) was adopted at Runwell Hospital in January, 1950 Mr Geoffrey Knight, then neurosurgeon to the hospital, was the first to perform the operation in this country, and he operated on the first 9 cases, which are not included in the present series

In view of the experience of Scoville (1949) and Rylander (1951) the selective undercutting operation has been restricted to the orbital cortex We have no experience of undercutting either the cingulate area or the superior convexity of the frontal lobe

Material

The series consists of 27 patients operated on January, 1951 They fall into two categories (and II)

A. Patients with well preserved personalities who suffe from long standing tension states, depression, or other e tional distress which had completely incapacitated th Each had received other forms of treatment without perma beneficial results

B Chronic disturbed psychotics, usually schizophre who already showed considerable deterioration and in w the aim was a nursing improvement rather than a cure

Serious postoperative defects would be discerned rea in the first group, but less readily in the second

Of the 27 patients 8 were men and 19 women 3 m and 10 women in category A, and 5 men and 9 wome category B Their ages ranged from 23 to 61 years, being between 23 and 40, and 10 between 41 and 61

Operation

The operations have been carried out under gen anæsthesia and along the lines described by Sco (1949) and by Tow and Lewin (1953)

It has not been found necessary to use a trephine la than 1¼ in in diameter, and this size is much easier to mani late than a larger one The trephine is placed so as to br the edge of the opening in the skull as close as possible to th orbital roof, and about 1 cm either side of the middle line. I some cases the frontal sinus has been traversed, when th has happened, the mucosa of the sinus has been tur inwards towards the nasal duct, and the mouth of the cavit lightly packed immediately with 'Gelfoam' liberally po dered with penicillin and sulphathiazole, any separ portion of mucosa attached to the disc of bone has b entirely removed, and the overhanging lip of bone (for the detached posterior wall of the sinus) has been nib from the disc In such cases prophylactic penicillin is g for five days after the operation, and no complication followed the opening of the frontal sinus

During the closure of the wound the discs are suture place, and the crevice which surrounds the replaced dis filled with bone dust, this prevents the unsightly defor which may become apparent some months after the opera when the scar tissue contracts and reveals a circular groo the site of each trephination

Provided the trephine openings are low in the frontal the tip of the frontal pole will be exposed after incisi dura mater, and the lightest degree of retraction will e one to elevate the frontal pole so as to bring the optic n into view at the point where it enters the optic foramen, on each side to measure its depth from the anterior surfa the pole This is the depth to which the "cut" shoul

TABLE II—CATEGORY B

Case no	Diagnosis	Duration of illness before operation (yr)	Length of follow up after operation	Result
14	Paranoid schizophrenia	6	2¾ yr	Improved
15	Paranoid schizophrenia	7½	2¾ yr	Improved
16	Paranoid schizophrenia	9	3¾ yr	Improved
17	Chronic schizophrenia	10	2½ yr	Not improved, died of intercurrent disease
18	Paranoid schizophrenia	3½	2¾ yr	Not improved, subsequently had standard leucotomy
19	Paranoid schizophrenia	36	2¾ yr	Improved
20	Catatonic schizophrenia	17	2¾ yr	Not improved
21	Paranoid schizophrenia	4½	2½ yr	Improved
22	Hebephrenic schizophrenia	3½	2½ yr	Not improved
23	Chronic paraphrenia	8½	2¼ yr	Improved
24	Schizophrenia	7	1¾ yr	Recovered
25	Catatonic schizophrenia	6	1¾ yr	Improved slightly
26	Catatonic schizophrenia	4	1¼ yr	Unchanged
27	Paranoid schizophrenia	15	10 mos	Improved

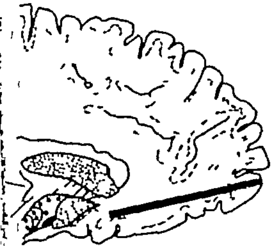
le and should not be transgressed If necessary the ımal arachnoid can be broken and cerebrospinal fluid oved by suction to gain extra room. The brain is now wed to resume its normal position and a suitable site on frontal pole is chosen for the cortical incision which runs nsversely for the full diameter of the opening in the bone l approximately parallel to the roof of the orbit The cise position of the incision depends on that of veins l on the cortical pattern large veins should be avoided if sible, and an incision through the summit of a gyrus avoids ll arteries hidden in sulci The obliteration of a large vein y give rise to local congestion, making the operation more icult. The cut is now made into the brain in a plane allel to the orbital surface of the frontal lobe and about m. under it. The correct direction is repeatedly verified by oving the spatula or other instrument used for the dissec n, and reorientating oneself in relation to the roof of the it. As the cut is deepened a narrow retractor is held so as maintain the orbital surface of the brain against the orbit en the required depth has been reached (centimetre rkings on the retractor are a great help) the cut is gradually tended medially until one estimates that the middle line been nearly reached, and then laterally until increased stance indicates that the lateral cranial wall is being proached.

Hæmorrhage in the depths of the cavity is controlled by common neurosurgical methods, which are used until gentle irrigation reveals that hæmostasis is satisfactory The under surface of the frontal lobe is now re-examined to make sure that no unsuspected hæmorrhage has taken place on the outside of the brain the dura mater is approximated with silk and covered with a piece of gelfoam



1—Sagittal view of brain 1 cm. lateral to line showing usual position of lesion in rbital undercutting: IC, internal capsule; thalamus. (Tracing from myelin-stained ction.)

It is essential that anæsthesia should be induced and maintained expertly so as to avoid all cerebral congestion due to ous obstruction, cyanosis or retention of carbon dioxide he brain bulges when the dura mater is opened one should it for this to subside, checking for possible defects in the ministration of the anæsthetic in these circumstances it is er to postpone operation than to attempt undercutting

he position of the head is important; if it is moderately ended the weight of the brain causes the frontal lobe to fall ay slightly from the roofs of the orbits, thus reducing the ee of retraction necessary

Orbital undercutting is a delicate operation which nnot be performed hurriedly It demands a much gher standard of technical skill and attention to detail an does leucotomy, and should never be undertaken ithout the full panoply of neurosurgical assistance and paratus Inspection of the specimen (figs 1–3) has phasised the narrowness of the margin between the sterior part of the orbital cortex and the inferior pect of the anterior extremity of the caudate nucleus t this depth deviation from the correct plane must early be very easy and damage in either direction or at o great a depth may lead to fatal consequences.

Results

Category A.—Of the 13 patients in this category 7 ave recovered 5 have improved and 1 has shown no hange Of the 12 recovered or improved 9 have been ischarged from hospital 7 of them are living normally home and working for the first time in many years; he remaining 2 are free from symptoms and are steadily mproving but have not yet fully adapted to the stresses of life outside hospital These patients have experienced marked subjective relief of their emotional tension, distress or aggressive tendencies, according to the diagnosis Experience has shown that improvement in social adaptation may continue up to two years after discharge

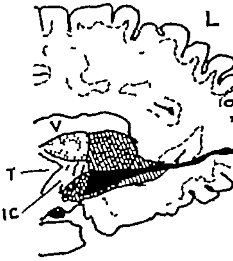


Fig. 2—Comparable (same scale) sagittal view of brain of case 12: IC internal capsule; T thalamus; V ventricle; black complete loss of tissue; hatched partial loss of tissue. (Tracing of fixed brain.)

Category B.—As was to be expected the results in this category are less favourable Only 1 has shown a social recovery but improvement has been evident in 8 of whom 4 have been discharged to their homes. This improvement has been greatest in patients who suffered distress because of hallucinations or displayed impulsive and violent behaviour However, our experience leads us to believe that undercutting of the orbital cortex is insufficient for the more severe schizophrenics because one such patient had afterwards to undergo a standard leucotomy Of the 4 chronic psychotics who were discharged 1 schizophrenic made a social recovery and has started working for the first time for many years, 2 have been relieved of their psychotic symptoms (1 is working full time and supporting her family, and the other lives a fairly normal existence and does some housework) the 4th patient, a young schizophrenic was discharged against advice and has not shown any improvement.

In both categories those patients remaining in hospital who were classified as improving have had considerable relief They are now nursed in better wards and can enjoy more freedom within the hospital

Postoperative Complications

There were no cases of clinically recognisable cerebral hæmorrhage following the operation Patient 5 in category A had epileptiform fits on the second day after the undercutting but has had none since Patients 2 and 8 in category A developed complete loss of the sense of smell, presumably through injury of the olfactory bulb tract or cortex. Patient 20 in category B had hyperpyrexia and coma for forty-eight hours but made an uneventful recovery

Incontinence of urine so distressing in many post leucotomy cases, is occasionally met with during the first

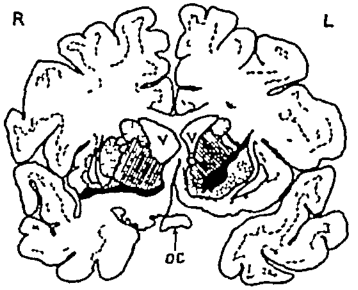

Fig 3—Coronal view of brain of case 12 at level of optic chiasma: OC optic chiasma; V ventricle; black, complete loss of tissue; hatched partial loss of tissue. (Tracing of fixed brain.)

week or two following orbital undercutting but has never persisted Except in patient 12 in category A, there were no serious or permanent postoperative complications This is in marked contrast to the standard leucotomy

Postoperative Personality Changes

The 27 patients have been thoroughly investigated for postoperative personality change, and the 24 who proved coöperative have also undergone psychometric tests by Dr Graham Foulds The 13 discharged patients have been followed up in detail at regular intervals, and not only have the relatives and the patients been interviewed, but in all cases the homes have been visited by one of our psychiatric social workers and sometimes also by one of us Special importance was attached to statements by relatives, not only on the improvement they noticed in the mental picture but also particularly on the development of undesirable symptoms In this respect the difference between the present patients and those who have undergone standard leucotomy is very striking Except patient 12, none of those in category A has shown any serious personality defect The same is true of the chronic psychotic patients, category B, though here it became less easy to distinguish between deterioration of the personality due to the psychosis and deterioration due to the operation Compared with changes seen after standard (or medial) leucotomy, there have certainly been no serious or unpleasant psychological or behavioural sequelæ There is, in our opinion, a quantitative rather than a qualitative difference There is some loss of spontaneity, which tends, however, to lessen as the months go by Some patients complain of an abnormal tiredness for the first few months Although abnormal emotional tension is eased, there is little blunting of affect—certainly never to the point of apathy For the first few weeks there is a tendency to emotional facility, with at times outbursts of laughter for little apparent reason, but this symptom has always subsided In the social sphere the recovered patients are able to work efficiently and enjoy their pleasures, contrasting vividly with post-leucotomy patients 2 of the chronic psychotic patients appeared to develop increased sexual drive However, in one of these cases there was evidence of eroticism before the undercutting It may well be that inhibition diminished

24 patients were tested psychologically four weeks after operation and 12 were tested again six to twelve months after operation The tests included Mill Hill vocabulary scale, progressive matrices, porteus mazes, thematic apperception test, Rorschach test, and Wechsler Bellevue test The outstanding features of the results so far obtained is their constancy and the absence of any sign of intellectual deterioration On the credit side are improvements in appetite, sleep, and sociability , thus patient 5 in category A, who had for years been habituated to amylobarbitone, could take little food, and was in danger of dying from starvation, quickly regained her appetite, put on weight, and could do without night sedation

Complications due to too Posterior Cut

Case 12 in category A—that of a woman of 54, with ten years' melancholia—demonstrates the danger of a lesion extending too posteriorly

After her undercutting operation in May, 1954, she was extremely drowsy for an abnormally long time She had to be fed and was incontinent She showed complete apathy, had a mask like expression, and developed signs of bilateral pyramidal damage and parkinsonism , she could not walk or stand The blood protein picture showed an absolute increase of globulin (total serum protein 6 3 g per 100 ml , albumin 2 2 g , globulin 4 1 g , albumin/globulin ratio 0 54) Within the globulin fraction the α_1 component showed a significant increase over the normal values The blood levels of urea, sodium potassium, calcium, magnesium, and chlorides were all normal, as was the CO_2 combining power The most striking feature, however, was intractable trophic ulcers both shoulders, the outer edges of both feet, the sacrum buttocks, the trochanters, the big toe joints, both heels, left external malleolus, the left fifth toe, and the left Some muscles and tendons had been eroded right thro and even the great trochanter had been eroded The ul were severely infected

In spite of intensive treatment the patient gradually deteriorated, lost weight, and eventually died, five and a h months after operation, from pneumonia, septic absc and cachexia At necropsy (Dr J A N Corsellis) the brain weighed 930 g , on both sides the surgical lesion had extended through the head of the caudate nucleus, the putamen the related segment of the internal capsule (solid black in fig 2 and 3) The area of partial damage however (as shown b hatching) appeared to be secondary and due to interference with the blood supply

In this case, it will be noted, the brain was abnormally small, and this may well explain why the section w carried too far back from the frontal pole Similar cases of severe trophic disturbances have been described following leucotomy where the cut has been made mo posteriorly than normally (McLardy 1950)

Illustrative Case-reports

Case 1 —A man, aged 34, was admitted to Runwell Hospital because of anxiety with nervous vomiting, which began during convalescence from pulmonary tuberculosis in September, 1950, and was causing physical deterioration He had alw been a nervous and sensitive person and had had bronch asthma since the age of 9 In 1946 he was discovered to ha pulmonary tuberculosis and received sanatorium treatm until October, 1949 Severe anxiety symptoms began when began to get up from a course of rest in bed. He felt afraid leaving his bed, had a sensation of "nervous tension in solar plexus," and would vomit, at first when anyth untoward happened, and then after meals regularly two three times a day He was preoccupied with the idea that tuberculosis would break out again at any time, and att of asthma, which had been rare while he was in the sanator began to recur frequently

When admitted he had already lost 21 lb Psychother and sedation failed to produce any improvement Sho after admission the tuberculosis was found to be active more, and he was treated by chemotherapy He bec increasingly anxious and vomited so much that it was im sible to continue giving him *p* aminosalicylic acid, and dietary intake was quite inadequate It was decided orbital undercutting, while his general condition rem good enough to permit the operation, was the only treat open, and the operation was performed under general an thesia in January, 1951

Progress After Operation —With continued chemother recovery from operation was uneventful After a week the patient appeared more calm, did not complain spontaneously of his fears, and took his diet well, though he denied improvement when questioned There was a gradual over all improvement in his anxiety symptoms during the following months except for two transient re-exacerbations of fear and vomiting eight and ten weeks after operation, which did not interf with the steady improvement in his pulmonary condition Eighteen months after the operation he was ambulant, longer afraid of exertion, optimistic about the future, making plans for a return to normal life He was still slightly anxious about meals, and feared a return of vomiting Unfortunately a series of upper respiratory tract infections delayed his discharge from hospital for some months, but he continued to gain confidence and was fit for discharge twenty two months after operation. There was no return of the vomiting, and he was eventually sent to a tuberculosis rehabilitation unit, where he started work as a welfare officer, driving his car about without any symptoms of fear or anxiety

Follow up —When seen nearly three years after the opera tion he had been disabled through an attack of asthma but was now well and was going back to his job He admitted that he was vastly improved and could do his work as far as his chest condition would allow him He was cheerful and there was no evidence of tension His parents stated that they could not see any detrimental traits following the operation.

Case 2 —A woman, aged 59, who had had two previous admissions to Runwell Hospital, was admitted for the th e in November 1951 The history of her neurosis went k for at least fifteen years and she was almost completely apacitated. She had depression anxiety and agitated pochondriasis She was given various forms of treatment luding E.C.T with no improvement She spent most of time in bed and, when at home could barely help with any usework, at times having to crawl about on her hands and ees.

On admission she was tense agitated and hypochondriacal th severe insomnia severe pains in the abdomen and head akness of the legs palpitations and pains in the chest e was preoccupied with her symptoms to the exclusion of ything else She swayed about, wringing her hands and oaning, continually asking for sleeping-drugs to ease her he symptoms had gradually got worse during the three or ur years before admission but were essentially the same as ough rather less severe than when she was first seen at the tpatient clinic in 1937 Bilateral undercutting of the orbital rtex was performed on Dec 24 1951

Progress After Operation.—For the first four days she was mewhat drowsy and was unaware that she had had an opera ion. Ten days afterwards she was placid and cheerful, with o agitation. She no longer spoke in a whining voice and nd-wringing was absent She could smile and laugh and id she felt much better There was no incontinence but she s rather slow in eating her food During the following two onths she steadily improved and in March, 1952 she was scharged symptom free

Follow-up —She has been visited in her home several times nce and her son also has been interviewed. When last seen ree and a quarter years after operation she was doing all her oking and housework. Whereas previously she never got up ntil 12 or 1 o clock, she was now up by 7 A.M She went out wo or three times a week and had taken up her hobbies again. he said: "There is a vast improvement in me I can now eep without drugs, I am not a bit depressed all those readful sensations are gone She read good books and had o difficulty in concentration Physically she was stronger and ad put on some weight

Case 6.—A woman, aged 38 at the time of operation had d paranoid schizophrenia for four years, during which she d been admitted three times to hospital At first her illness s characterised predominantly by apathy withdrawal and accessibility She had auditory hallucinations and delusions a persecutory nature—e g that she was always being atched by radio and television and that someone else came to the house to usurp her place whenever she went to bed went out. She believed that her husband was unfaithful her and she was frigid towards him and she lost interest in r children. She was disconnected in conversation and owed thought blockage Eighteen months before operation e began to be aggressive and attacked her husband and e nurses. She became increasingly violent and impulsive pparently in response to hallucinations. Orbital under tting was performed there was excessive bleeding at peration, and generalised epileptiform convulsions came on at evening She was incontinent for six days but after this nvalescence was smooth

Progress After Operation —A week after operation she was ill extremely apathetic but was coöperative and denied ving hallucinations. After a month she was showing more terest in her surroundings, attending occupational therapy lping with light duties on the ward and keeping herself esentable She remained coöperative and well conducted nd conversed freely There was no tension and no evidence f hallucinations nor did she voice any delusions. She went ome three months after operation and was discharged after further five weeks. At home she took up her duties in the ouse and looked after her children, and relations with her usband became satisfactory

Follow up —Seen about twenty-one months after the operaion she remained very well She was contented and there was o evidence of tension or hostility or of delusions or hallu inations; these had petered out Marital relations with er husband had become perfectly normal. She was now oing most of the housework cooking and cleaning though he did not often go shopping She had become affectionate towards her husband and children. She did not tend to lie n bed in the morning but made an early start with her housework. The husband remarked that the only thing he noticed wrong was that she could *not plan things well sometimes* showing lack of foresight but apart from that he regarded her as perfectly normal.

Case 8 —A woman aged 34 had had a chronic anxiety state with panic attacks for four years Depression and anxiety had been developing since early 1949 before which she had had a well integrated personality and held responsible executive posts She improved somewhat at first and left hospital in July 1950 only to be readmitted in April 1951, with an exacerbation of anxiety and panic attacks She was now extremely tense and trembly showing tachycardia and complaining of pains in the chest weakness of the legs and loss of energy and self-confidence In spite of sedation and psychotherapy she did not improve She had slight myxœdema following a thyroidectomy, but this was kept well under control with small doses of thyroid. For the next two years she continued in more or less the same condition. She was often lacrimose easily upset and complaining of constant fears No physical treatment improved her condition She was restless, irritable and at times excitable and she continually complained of tiredness. She underwent an orbital undercutting operation in April 1953

Progress After Operation —Immediately afterwards she was completely relaxed and at ease There was no evidence of depression and the crying bouts ceased She was amnesic for the operation She continued to make good progress and four months after the operation she was discharged and went to live with a friend who knew her very well.

Follow-up —She has been seen on numerous occasions and her social recovery has been maintained for the past two years Unfortunately she has severe purulent sinusitis which gives rise to headaches and muzziness At times she is anxious about her health but this appears to be a normal reaction Her friend is extremely pleased with the result The patient looks much better physically She can do her shopping though she cannot do her work. She still complains of tiredness and lethargy but she mixes much more socially with other people and remains quite free from neurotic symptoms.

Case 9 —A woman aged 50 began to have chronic melancholia at the menopause three and a half years before operation Her previous personality was over-conscientious and rather obsessional Five months after cessation of her periods she was admitted to the hospital under certificate after a suicidal attempt with aspirin She was depressed and expressed numerous delusions of guilt—e.g that she was contaminating all those around her and that she was the source of all the cancer tuberculosis, and blindness in the world. She had auditory hallucinations and heard people accusing her of sexual misdemeanour At this time she was experiencing menopausal vasomotor symptoms. Although she responded well to convulsion therapy she relapsed within a few months and after the third course of treatment the remission lasted only ten weeks. Recurrence of depression was accompanied by retardation; she lost all interest in life and in her relatives felt that all contact with other people was wicked and refused her food At the time of orbital undercutting she had been continually depressed for ten months

Progress After Operation —A week after operation she showed clear improvement. She was only mildly depressed showed affection for her relatives and took her diet with little persuasion Improvement continued and melancholic symptoms gradually faded out Two months later she was cheerful and active, eager to help with work on the ward and sociable and she liked to attend all the social functions in the hospital though she still occasionally expressed self accusatory delusions. She left hospital on trial and was discharged five months after operation.

Follow up —She has been seen regularly at home where she lives with her sister and as an outpatient during the year that has elapsed since her discharge and has remained quite well She shows no depression or delusions is active neat and tidy (still having a keen regard for cleanliness and orderliness) and feels capable of doing her share of household duties and shopping She likes to go out a good deal and enjoys radio and television though she finds her interest in reading somewhat diminished. Her sense of smell is absent since the operation. She looks considerably younger and smarter than before

Case 11 —A woman, aged 29 had had severe anxiety symptoms with depersonalisation for two and a half years before operation Her illness began suddenly after a minor bicycle accident in which she was not injured She was anxious and afraid to leave the house and to stay in the house by herself and she could not believe in the reality of [illegible] ment or in her own reality She could not do [illegible] and was continually preoccupied with her symptoms She was admitted to other hospitals on three occasions before her admission to Runwell Hospital and had received various courses of treatment, including E C T and insulin therapy, without relief from her symptoms Observation for nearly a year before operation showed her to be continually complaining of the symptoms and importuning for reassurance about her unreal feelings "Am I alive, or am I dead? Is it today? When will things look real?" She said she could not think of anything else or enjoy any activity There were periods of agitation when she was unable to sleep, and she took little interest in her appearance

Progress After Operation —After operation she was no longer agitated, slept without sedation, and was free from feelings of unreality, she kept herself well occupied with ward work and occupational therapy, and took full advantage of social facilities She conversed freely and easily, laughed, and enjoyed herself She was discharged six weeks after operation and at once took up her management of the home and her old interests

Follow up —She and her husband were seen separately three and a half months after discharge She had put on weight, previously having been thin and undernourished She looked considerably younger Her husband said there was a dramatic improvement There was no agitation or depression She was looking after her home very well and getting up early She no longer presented any symptoms of depersonalisation and had not once asked for reassurance She found that her housework was not quite enough and would like more to do She had normal initiative She enjoyed such entertainments as cinema, radio, and dancing, and there was no evidence of impairment of drive or concentration At times she complained of tiredness, but this in no way interfered with her activities She has now obtained employment and is working full time

Case 13 —A dock labourer, aged 31, had depression with paranoid delusions for three and a half years before the operation Previously he had enjoyed excellent health except for an accident at the age of 30, when he fell 60 feet, fracturing his spine and wrist, without persisting disability At the onset of his mental symptoms he would return from work morose and disgruntled and would sit brooding for hours Shortly after this he expressed paranoid ideas about his work-fellows, became increasingly agitated, depressed, and sleepless, and believed that men were surrounding the house, talking about him, and trying to get in at him This culminated in his admission to hospital after attempting suicide by cutting his throat

On admission he was tense, depressed, and retarded, with little spontaneous activity, and showed a tremor of his hands and lips He said that his work mates had "put the pressure" on him, had called him a "wrong 'un" and a "copper's nark." He heard a voice in his head repeating "He is insane, he is insane" and other derogatory remarks He said he had been forced to protect himself and on one occasion had attacked a work-fellow with a knife He had also been drinking heavily for some months He was full of remorse for his wrong doings and felt that he was unworthy of his family

Response to E C T was good, and he left hospital and returned to work after eight weeks, but he soon began to drink again, and later became depressed and was readmitted, having been home for six months after a second suicidal attempt Further courses of E C T produced only temporary improvement, and he remained in hospital in a depressed and deluded state Orbital undercutting was performed three years after his original admission, and at this time he had been continually depressed for a year

Progress After Operation —After operation tension was still present at times, but he was not depressed. During the two postoperative months before his return home he gradually lost his tension, and was happy and friendly with the other patients whom he had previously believed were talking about him

Follow up —Four months after operation he remained well and entirely free from psychotic symptoms, depression, and tension and appeared placid and contented He looked after himself well spontaneously, occupied himself with jobs about the house, reading, and going for walks Immediately on discharge he was eager to start work again He was advised to take it easy for a while, but there is no doubt that he is now fit to do a full day's work

Discussion

Scoville (1949), who devised the first undercutting operations as opposed to topectomies and gyrectomies, suggested three sites for the operation according to the nature of the disorder (1) the superior convexity of the frontal cortex corresponding to Brodmann's areas 9 and 10; (2) the medial frontal cortex cingulate area, and (3) the orbital cortex areas 11 and 13 Scoville regards the undercutting of the orbital cortex as the ideal operation for the relief of chronic neuroses and milder mood disturbances, because of the almost complete absence of personality changes Our best results are in just these conditions—i e, chronic anxiety states and chronic depressions—but some of the patients with a paranoid psychosis who had much tension or suspiciousness also benefited greatly from the operation On the other hand, in severe psychotics the operation may be found insufficient quantitatively As mentioned above, case 5, in category B, had subsequently to undergo a standard leucotomy

In such an unpredictable field as neuro anatomy, especially in the present state of our knowledge, a discussion on correlation between clinical findings and operative lesions, examined post mortem, is not likely to be very profitable Much more material from recorded cases will have to be examined It may be of interest, however, to note that, according to Fulton (1951), the hypothalamus projects to the cerebral cortex by way of two main groups of thalamic nuclei, the anterior and the dorsomedial nuclei As regards the dorsomedial nucleus, the most medial portion is that which receives neural messages from the hypothalamus, and this projects to the orbital surface, especially the anterior part and the frontal pole (Le Gros Clark 1948, Le Gros Clark and Meyer 1950) The lateral part of the dorsomedial nucleus sends fibres to the convexity of the frontal lobe Neurophysiologists suggest that this tract provides an essential relay mechanism through which the activities of the hypothalamus can immediately influence those of the higher functional levels of the cerebral cortex Interruption of the pathway between the magnacellular portion of the dorsomedial nucleus and the orbital cortex may diminish to a very large extent the number of impulses influencing "consciousness," and in this way, it has been argued, provide relief from a state of tension

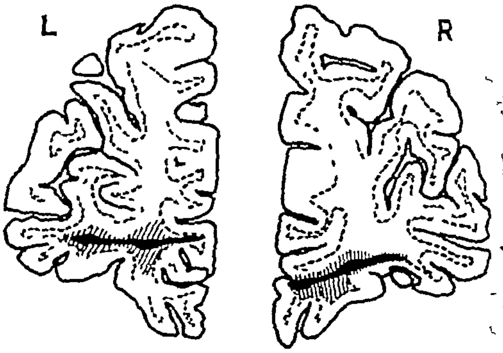

Fig 4—Coronal section 3 cm posterior to frontal pole (case 17): black, complete loss of tissue, hatched, partial loss of tissue (Traced from myelin-stained section)

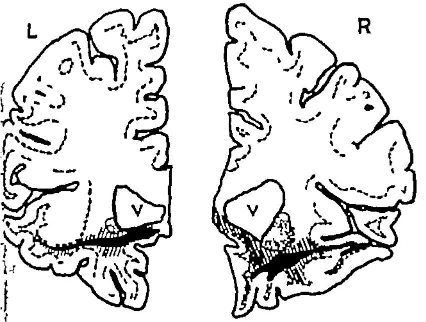
In this connection the following neuro anatomical observations are of importance Patient 17, in category B, a woman of 26 with long standing paranoid schizophrenia and much deterioration, who was operated on 8 October, 1951, died of intercurrent disease (carcinoma of the ovary) two and a half years later We are indebted to Dr Corsellis for the following report

"At the frontal pole on both sides there was a horizontal slit-shaped cavity 2 0 cm × 3 0 mm, which first penetrated the polar cortex and then opened out into the white matter deep to the orbital surface On both sides, at a coronal level 3 0 cm. behind the frontal pole (fig 4), the medial two-thirds of the orbital cortex had been undercut, although on the left



g. 5—Coronal section 4 cm. posterior to frontal pole (case 17): V ventricle; black complete loss of tissue; hatched partial loss of tissue. (Tracing from myelin-stained section.)

e the lesion was slightly more dorsally placed The widest onal extent of the undercutting was at a level 4·0 cm from e pole (fig 5) when the entire width was affected Posterior this level the lesions rapidly narrowed and they died out ntral to the most anterior limits of the heads of the caudate cleus—i.e., 5·0–5·5 cm. from the frontal pole (fig 6)

Histologically the cavities were encircled by a narrow ge of demyelination always less than a few millimetres deep part from the entry wounds the frontal cortex was not preciably affected and the only other changes were condary ones related to the primary lesions. These included lateral degeneration of a small segment of the internal psule and of the medial part of the dorsomedial nucleus of e thalamus.

Although this case, from a clinical point of view is a d example because the patient was already grossly teriorated when operated on the neuro anatomical anges are of great interest because they seem to confirm at at least part of the tracts carrying visceral impulses m the hypothalamus via the thalamus had been ered The results of a more detailed investigation of e brain by Dr Corsellis will appear elsewhere No hard d fast conclusion can of course, be drawn from this gle specimen; but continued study along these lines specimens become available will further our progress wards a more definitive method of relieving mental order by operation

Summary

The results in 27 patients who have undergone bilateral dercutting of the orbital cortex are described

The patients were divided clinically into two groups: with well preserved personalities, of whom 7 were ronic neurotics (category A) and 14 who were deteriorated psychotics (category B) In category A 9 patients were afterwards discharged, of whom 7 were regarded as recovered and 2 as improved In category B 4 patients were discharged, of whom 1 was a social recovery 2 were improved and 1 was not improved

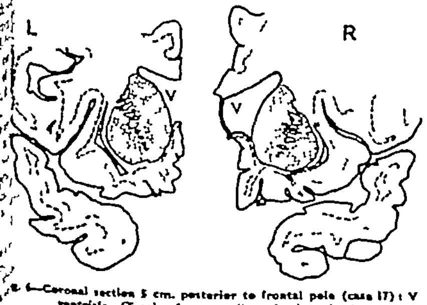
Of the remaining 3 in category A 2 improved in category B 5 did not improve and 1 of these subsequently underwent a standard leucotomy

There was no immediate postoperative death, but 1 patient with an abnormally small brain, in whom the cut had been carried too posteriorly died from extensive trophic ulceration five and a half months after operation

The postoperative personality changes have been negligible or very slight and have never reached the disturbing proportions seen after standard or medial leucotomy

The absence of serious personality defects and other complications after undercutting of the orbital cortex renders this operation preferable to standard leucotomy in chronic and apparently intractable neurosis or depression

This operation is also to be recommended in well preserved psychotics who exhibit tension and psychomotor unrest due to delusions and hallucinations



g. 6—Coronal section 5 cm. posterior to frontal pole (case 17): V ventricle. (Tracing from myelin-stained section.)

Our thanks are due to Dr J A. N Corsellis, neuropathologist to Runwell Hospital for neuropathological reports and to Dr Graham Foulds, senior psychologist to the hospital, for psychological investigations We are also greatly indebted to Dr S Wiseberg registrar at the hospital for assistance in the preparation of case histories and follow up interviews

This report describes thrush œsophagitis in two new born infants in whom a disorder of swallowing led to aspiration pneumonia Treatment with hydroxystilbamidine not previously used in this condition was effective.

Case reports

Case 1—A girl aged 17 days and weighing 6 lb 6 oz (birth weight 6 lb) was admitted on July 24 1954 with a 24 hour history of vomiting and refusal of feeds.

Her general condition was fair A white membrane from which *Candida albicans* was isolated covered the tongue and buccal mucous membrane The vomiting and refusal of feeds suggested spread of the thrush to the œsophagus Treatment with gentian violet (1% paint to the mouth, and 0 01% 4 ml three times daily to swallow) was started

During the next 3 days reluctance to feed and occasional vomiting persisted, and her general condition remained unchanged Then, on July 28, she developed bronchopneumonia, confirmed by radiography Despite a course of sulphadimidine her condition deteriorated further during the next 48 hours The oral thrush persisted, and a profuse viscid discharge now poured from nose and mouth On July 30 a course of penicillin, previously avoided because of the thrush, was started, but the downhill course continued, and it seemed that the infant had not much longer to live At this stage vomiting, inability to swallow either food or the secretions from the nose and mouth, and repeated attacks of cyanosis despite oxygen therapy were the outstanding features The pulse rate was 180 and respirations were 80 per min Feeds had to be given by œsophageal tube passed through the mouth, because the nostrils were blocked by œdema and secretions Frequent sucking out of the nose, mouth, and pharynx was necessary to save the infant from suffocation On July 31 the house physician noted in the case records "I fear the worst"

On Aug 1 sulphadimidine, penicillin, gentian violet, and œsophageal feeds were discontinued, and an intravenous infusion was started At 10 P M the first dose of hydroxystilbamidine was given 15 mg (5 mg per kg body weight) dissolved in 0 75 ml of water was injected slowly into the rubber tubing above the drip chamber This dose was repeated 12-hourly Next morning she had improved remarkably, her respiration was slower (64 per min) and less laboured, and her pulse rate had fallen to 140 That night, however, she had a further attack of cyanosis This led us to start a course of streptomycin in addition to the hydroxystilbamidine, because it was impossible to decide whether there was a true thrush pneumonia or a bacterial aspiration pneumonia secondary to the thrush œsophagitis and stomatitis The latter diagnosis was supported in retrospect by the isolation of a coagulase positive *Staphylococcus aureus*, sensitive to streptomycin but insensitive to penicillin, from a blood culture taken on Aug 1

During the next week the baby improved steadily The nasal discharge and obstruction cleared within 24 hours of starting treatment with hydroxystilbamidine, the oral thrush membrane disappeared rapidly, no further *C albicans* was isolated, and radiography on Aug 6 showed decreased pulmonary involvement Because of this improvement and also because signs of thrombophlebitis had appeared, intravenous fluids and hydroxystilbamidine were stopped after a 6 day course, and oral feeds were begun again She took small amounts well, but, as the feeds were increased, she again started to cough and splutter, and on Aug 8 she had an attack of cyanosis On Aug 11 fluoroscopy showed bilateral basal collapse as well as incoördination of swallowing, which caused much iodised oil to enter the tracheobronchial tree Œsophageal feeding was recommenced and again she improved, though fluoroscopy on Aug 20 showed persistence of the incoördination

On Aug 26 feeding by teat was attempted once more, and this time there was no spluttering or choking Further progress was very satisfactory The baby was discharged on Sept 19, and when she was last seen on Nov 22 her condition was excellent, she had gained 4 lb and a chest radiograph was normal

Case 2 —A boy, aged 24 hours, was admitted on Oct 19, 1954 Pregnancy and delivery normal Birth weight 7 lb A few hours after birth a generalised petechial rash had appeared.

His condition was good, and there were no other abnormal signs A blood-count showed 56,000 platelets per c mm and 6000 leucocytes (1140 polymorphs) per c mm The discovery of thrombagglutinins (Stefanini and Dameshek 1953) and leukagglutinins (Dausset et al 1954) in the sera of the infant and of his mother explained the purpura and granulocytopenia

No fresh petechiæ appeared after admission, although the platelet-count on Oct 23 was only 32,000 per c.mm On Oct 25, however, he had purulent conjunctivitis of the right eye, omphalitis, septic blisters on the face, and oral thrush Oral and conjunctival swabs grew *C albicans* A *Staph aureus*, sensitive to aureomycin but insensitive to penicillin, was also isolated from the conjunctiva The septic skin lesions, conjunctivitis, and omphalitis cleared rapidly with a 6-day course of aureomycin 20 mg 6 hourly The thrush stomatitis was t[illegible] gentian violet paint Occasional vomiting suggested spread of the thrush to the œsophagus, so the baby was also given gentian-violet to swallow

Even after aureomycin had been discontinued on Nov 1, the thrush spread further until the tongue and oral mucosa were completely covered, and on Nov 2 *C albicans* was isolated from stomach washings A blood count on Nov 3 showed 7400 polymorphs per c.mm but still only 135,000 platelets per c mm His condition gradually deteriorated

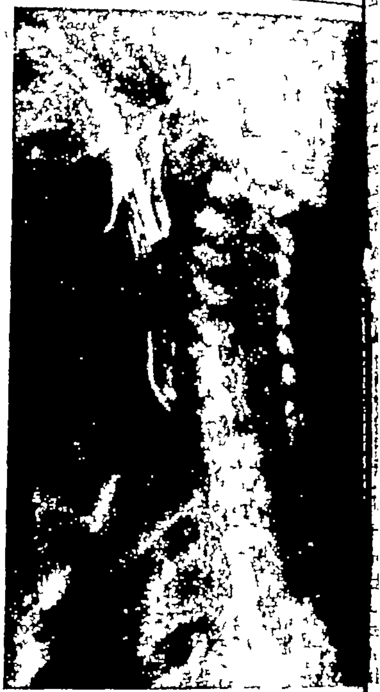

Fig 1—Case 2 Incoördinated swallowing oil has passed into nasopharynx and trach

He became reluctant to take feeds, milk was retained in mouth and dribbled from the corners, there was splutte and he had several attacks of cyanosis It was often nece to suck out his nose, mouth, and pharynx, where much st mucus accumulated and interfered with breathing

On Nov 4 one of us (R A) examined the infant flu scopically the contrast medium was held in the mouth rejected, very little was swallowed If contrast me was injected into the back of the mouth or pharynx, swallo was seen to be incoördinated Iodised oil passed up into nasal cavity and down the trachea, little entered the phagus (fig 1) If oil was injected directly into the œsoph it passed down reasonably well The picture was th pharyngeal incoördination of swallowing The lungs were

During the next 24 hours his condition deteriorated fu The temperature rose to 101 6°F, the pulse rate to 19 the respirations to 90 per min

On Nov 5 local treatment to the mouth was discont and intravenous fluids were substituted for oral feeds S taneous treatment w hydroxyst bamidine mg 12 hou was start being give the sa method as case 1 Th improveme during th next 2 da was remark able Afte hours trea ment wit hydroxyst bamidin cultures fr oral swabs a stomac washings d not grow *albicans* Th oral membr started to on Nov 7, by Nov 12 mouth

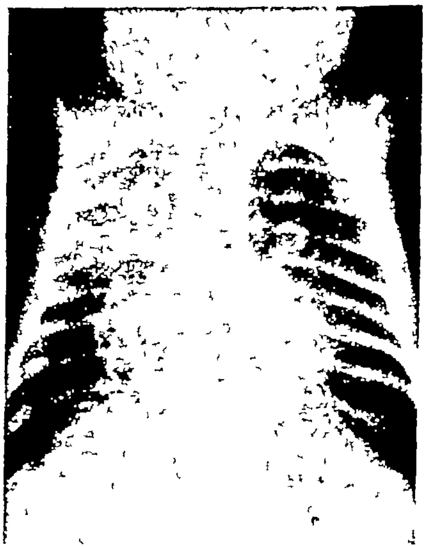

Fig 2—Case 2: aspiration pneumonia.

ered with healthy looking mucosa. Because of this rapid rovement, and also because the leg into which the intraven fluids and the drug had been given showed signs of throm hlebitis, hydroxystilbamidine was stopped on Nov 9 and feeding restarted Within 24 hours all the symptoms of ryngeal incoördination recurred with reluctance to feed spluttering Frequent suction of secretions from the mouth nostrils was necessary Oral feeding had obviously been arted too soon.

On Nov 13 the baby developed pneumonia: a radiograph wed extensive consolidation in both lungs, consistent with ration into the bronchial tree (fig 2) A blood-count wed 4500 polymorphs per c.mm and 320 000 platelets c.mm *Staph aureus* was isolated from oral and nasal retions. Treatment with streptomycin and erythromycin, which the organism was sensitive was started The infant nursed in oxygen and tube fed After an anxious few days again improved and fluoroscopy on Nov 22 showed a mal though rather slow swallowing reflex. Consequently l feeding was restarted and further progress was uneventful. radiograph on Dec 8 showed resolution of the consolidation, d he was discharged on Dec 11 When he was last seen on c. 31 his condition was excellent and he had gained 2lb ce discharge.

Discussion

cidence

Thrush infections are common during early infancy dlam and Henderson (1942) swabbed the mouths of unselected infants at intervals during the first ten ys of life they isolated *C albicans* from 11 all of om developed clinical thrush a further 3 infants, king a total of 23% developed thrush before leaving pital. Anderson et al (1944) found an incidence of 7% of clinical thrush in newborn infants and, like dlam and Henderson noted that, whenever *C albicans* s cultured thrush developed in two or three days. e use of antibiotics has made thrush infections even re frequent (Amlie 1952 Holzel 1953 Nikolowski 1953) ommonly these infections are mild remain localised the mouth or skin and respond readily to gentian let or to borax in glycerin Probably such mild cases en remain undiagnosed and recover spontaneously t infrequently however the infection takes a less lign course spreads beyond the mouth into the rynx oesophagus larynx, and bronchi or rarely into lungs or blood-stream, and may kill the infant

bbs (1938) at the Children s Hospital, Birmingham found ng a three-year period 22 instances of thrush oesophagitis cropsies on infants. He regarded the thrush as the cause eath and not as a terminal complication of some other dition. Ludlam and Henderson (1942) over a four year od found 20 cases of thrush oesophagitis at necropsy The nce in infants who died after forty eight hours of life 6·6% The thrush appeared to be the cause of death in cases. In another series, of 2 40 infants who survived for e than forty-eight hours the same observers found 163 of thrush. 20 of these died from various causes necropsy done in 18; in 8 the thrush had spread to the pharynx l in 7 of these it had also invaded the oesophagus In 2 s it had spread to the stomach Lederer and Todd (1949) nd either pharyngeal or oesophageal thrush in 7 of 28 ropsies on newborn babies and in 10 of 170 necropsies on ants 1–12 months old

Whereas the diagnosis of oral thrush is usually easy n thrush in early infancy is often unrecognised par ularly when it occurs without oral thrush The atest difficulties however arise in the diagnosis of ush involving the pharynx oesophagus, larynx or e respiratory tract below the larynx The *British dical Journal* (1950) stated that the diagnosis of tabuccal thrush is a matter of conjecture and can nerally be made with certainty only after death derer and Todd (1949) thought that the diagnostic ficulties in the living and even at necropsy might be ponsible for fatal thrush lesions remaining undetected d unrecorded In the presence of oral lesions a deteri ation in an infant s condition will suggest extension of e thrush; but pharyngeal lesions may occur in the sence of or with only inconspicuous oral thrush

Clinical Features

In view of the difficulty of exact definition of the extent of the thrush infection, we shall for convenience refer to the syndrome as "thrush oesophagitis," realising that the pharynx and respiratory tract may also be involved Ebbs (1938) Ludlam and Henderson (1942) Adams (1944) and Lederer and Todd (1949) described the clinical features of this syndrome Their descriptions agree closely with each other and with the findings in our cases

Initially there is crying during feeds and regurgitation or vomiting, which is occasionally projectile, the vomit may contain blood. Then feeds are refused or retained in the mouth and dribble from its corners, much thick mucus accumulates in the mouth and nose Despite correction of dehydration an intense toxæmia develops often with a subnormal temperature During feeds attacks of cyanosis occur which Ebbs (1938) ascribed to aspiration of vomit Lederer and Todd (1949), however postulated pharyngeal incoördination leading to direct entry of milk into the respiratory tract. This hypothesis we have been able to prove by fluoroscopy and by ciné-radiography by the technique described by Astley (1955),

In both children there was a disorder of deglutition largely restricted to the pharynx transit through the oesophagus was relatively normal and only hindered by respiratory distress. Much of the opaque medium remained in the pharynx for some seconds contrasting strongly with the normal rapid passage The pharyngeal space remained open and its communicating passages patent; the larynx did not rise and the nasal cavity was not closed off by the soft palate In consequence iodised oil passed upwards into the nose and downwards into the larynx and tracheobronchial tree During much of the time the epiglottis remained erect amidst the contrast medium There was not however an absolute paralysis; occasionally the larynx rose and the pharyngeal space was obliterated Infrequently a bolus passed much more normally and the epiglottis turned down with it in the usual manner (Ardran and Kemp 1952)

These findings suggest that the pneumonia, which has been regarded by previous writers as such a constant terminal event (Ebbs 1938 Ludlam and Henderson 1942 Glanzmann and Riniker 1950) is at least sometimes due to a complicating disorder of swallowing A true thrush pneumonia is probably rare (Adams 1944 *British Medical Journal* 1950) the causal organisms usually being secondary pyogenic invaders, particularly *Staph. aureus* (Ludlam and Henderson 1942, Adams 1944 Lederer and Todd 1949, Glanzmann and Riniker 1950, Amlie 1952)

Treatment with Hydroxystilbamidine

Hydroxystilbamidine is one of the series of aromatic diamidine compounds synthesised by Ashley and Harris (1946) in the laboratories of Messrs May & Baker Fulton (1944a) found it of prophylactic value against *Trypanosoma rhodesiense* inoculations in mice In *Leishmania donovani* infections in golden hamsters it was as effective as stilbamidine (Fulton 1944b) Hydroxystilbamidine has been used in the treatment of multiple myeloma (Snapper 1948) kala azar (Sen Gupta 1949) mucocutaneous leishmaniasis (Snapper 1952) blastomycosis (Snapper and McVay 1953 Smith 1953 Colsky 1954 Sutliff et al 1954 Weinberg et al. 1954) and a coccidioidal infection involving a single bone (Grebe 1954) Trigeminal neuropathy, which is a relatively frequent and distressing complication of stilbamidine treatment (Napier and Sen Gupta 1942 Collard and Hargreaves 1947, Schoenbach and Greenspan 1948) and led Snapper et al (1952) and Curtis et al. (1954) to abandon its use has not been reported after treatment with hydroxystilbamidine

We have not found an account of thrush infections in man treated with stilbamidine or hydroxystilbamidine A trial of these compounds was suggested by their success in other mycotic infections Solotorovsky et al (1954) showed that stilbamidine and hydroxystilbamidine are moderately active against *C albicans* in vitro but inactive in mice However, failure of a drug to cure fungus infections in mice does not necessarily imply failure in man For example, Schwarz and Adriano (1953) failed to arrest experimental blastomycosis in mice with stilbamidine, yet in human infections its value is beyond doubt Schoenbach and Greenspan (1948), in their excellent review of the aromatic diamidines, state that the host drug relationship is as important as the host parasite and parasite drug relationships Smith (1953) and Snapper and McVay (1953) expressed similar views

The pharmacology of hydroxystilbamidine has been reviewed by Snapper et al (1952) and Smith (1953) The following brief account is largely based on these reviews and that of Schoenbach and Greenspan (1948), which deals with the aromatic diamidines in general

Hydroxystilbamidine is 4 4′ diamidino 2 hydroxystilbene The compound used in our cases was 4 4′ diamidino 2-hydroxystilbene di β hydroxyethanesulphonate, which contains 54% of base For brevity we have used the term hydroxystilbamidine in place of the full chemical name of its salt After an intravenous dose of 2 mg of stilbamidine or hydroxystilbamidine per kg body weight only about 15% is excreted in the urine in twenty four hours After daily doses for seven or eight days the amount excreted in the urine increases progressively to a maximum of 70–80% in twenty-four hours, this suggests that the body proteins gradually become saturated with the diamidines, after which the excess is largely excreted in the urine It is likely that the remarkable adsorptive qualities of the diamidines account for the progressive improvement which may take place long after cessation of therapy Snapper et al (1951) found traces of diamidines in the body three years after administration

Administration —Sen Gupta (1949) and Grebe (1954) observed that hydroxystilbamidine given intramuscularly caused pain at the site of injection, Smith (1953) condemned the intramuscular route for the same reason and as a possible cause of local necrosis The intravenous route appears preferable, though Snapper and McVay (1953) noted little pain or tissue reaction after intramuscular injection with procaine (75 mg of hydroxystilbamidine in 2 ml of 5% glucose in physiological saline solution containing 20 mg of procaine) Snapper (1948) and Sen Gupta (1949) dissolved hydroxystilbamidine in 10 ml of water and 25 ml of 25% glucose respectively and injected it slowly into a vein Snapper (1952), Smith (1953), Colsky (1954), Grebe (1954), and Weinberg et al (1954) gave 225 mg daily (the dose for adults) dissolved in 200–300 ml of 5% dextrose or of saline solution by continuous intravenous drip over periods ranging from half an hour to three hours Continuous drip is probably preferable to intravenous injection, which may be followed by thrombophlebitis After rapid injection transient pallor, dizziness, a fall in blood pressure, and tachycardia have been reported (Schoenbach and Greenspan 1948, Smith 1953)

Published reports deal mainly with adults, and we have been unable to find an account of hydroxystilbamidine used in infants At this age daily intravenous injections are difficult to give In our two cases we discontinued oral feeds, administered fluids by continuous intravenous drip, and injected the hydroxystilbamidine (15 mg in 0 75 ml of water) slowly into the rubber tubing above the drip chamber The occurrence in both infants of venous spasm after injection, and later of thrombophlebitis, suggests that it might be better to give the compound by continuous drip over two or three hours

Smith (1953) noted that a precipitate forms when concentrations greater than 0 5% of stilbamidine are added to human serum, and suggested that this may explain the occasional immediate toxic effects after intravenous injection of concentrated solutions We also noticed a precipitate in the drip chamber when hydroxystilbamidine was injected into the rubber tubing while plas[illegible] being infused, though our infants showed n[illegible] toxic effects After this observation the hydroxystilbamidine was injected into glucose and saline solutions, with which no precipitate formed

Dose —The dose commonly recommended for adul 3–5 mg per kg body weight daily or on alternate da As infants usually require relatively greater amounts chemotherapeutic agents, we decided on a dose of 5 m per kg, and the infants' very poor condition led us t repeat the dose twelve hourly Treatment was contin for six and four days respectively (total doses 180 m in case 1 and 120 mg in case 2) Because of the rate of excretion of hydroxystilbamidine, the rapid appearance of the thrush lesions, and the developme thrombophlebitis we decided against a longer cours treatment The *optimum therapeutic régime* will only discovered after further *trials of hydroxystilbamidine* in severe thrush infections Our experience with the two cases has convinced us that such trials are justi whenever the response to simpler remedies is unsa factory, especially when *the infection* has spread bey the skin or the mouth

Adjuvant Therapy

As secondary pyogenic invasion is important, it advisable in the more severe cases to use a potent bacterial agent in addition to hydroxystilbamidine—in case 1, where streptomycin was given The disapp ance of the thrush membrane from the mouth must be taken as evidence that there can be a return to feeding, this mistake, which we made in both ca led to the development of pneumonia There w latent period between the disappearance of the membr and the return of normal deglutition—an observatio not recorded previously, probably because before advent of hydroxystilbamidine no such seriously infant had survived It appears advisable to fo intravenous feeding, which is necessary at the heig the illness, by a period of tube feeding We su that after the disappearance of the thrush memb fluoroscopy should be employed to demonstrate no swallowing before oral feeds are restarted

Summary

A severe thrush infection of the upper alimentary respiratory tracts may be accompanied by a cl picture due to incoordination of swallowing

This incoördination may lead to pneumonia

Hydroxystilbamidine was an *effective form of* t *ment in the two cases described*

Secondary pyogenic invasion is an important comp tion requiring additional treatment

Disordered swallowing may persist for several after the disappearance of the thrush membrane f the mouth, fluoroscopy is advisable before rec mencing oral feeding

We are indebted to Dr H S Baar for suggesting demonstrating the presence of leukagglutinins and thr *agglutinins in case 2*, and to Dr W R Thrower who first d our attention to the possible value of hydroxystilbamid thrush and helped us with case 1 We gratefully acknow the invaluable nursing services of Sister J Woodward her staff Messrs May & Baker supplied the hydrox *bamidine*

Addendum

Since submitting this report for publication we have tre *a third infant suffering from thrush* œsophagitis, incoördi tion of swallowing, and aspiration pneumonia The c was 3 weeks old Hydroxystilbamidine was given slo over two to three hours by continuous intravenous drip a scalp vein The compound was *given twice* daily for *days* No thrombophlebitis occurred and we were abl use the same vein throughout this period The *baby* an excellent and rapid recovery

The heterocyclic sulphonamide 2 acetylamino 1 3 4 iadiazole-5-sulphonamide (acetazoleamide Diamox, derle), inhibits the enzyme carbonic anhydrase, its ain pharmacological effect being exerted on the renal bule cells (Miller et al 1950 Berliner et al 1951) ading to increased urinary excretion of sodium tassium, and bicarbonate reduced excretion of monium ion, a rise in pH of the urine and a fall in the um-bicarbonate level and in pH of the blood (Nadell 53 (ounihan et al. 1954)

The treatment of respiratory acidosis with acetazole ide was suggested by Nadell (1953) who obtained vourable results in 6 cases Similar results were tained by Heiskell et al (1954) in 4 ambulant patients th pulmonary emphysema and by Ruskin (1955) in case of cor pulmonale

The rationale of this therapy was elaborated by Nadell 953). She found in 2 controls and in 5 of 6 patients th respiratory acidosis that when acetazoleamide was t given both the serum bicarbonate level and the I of the serum fell with continued therapy the pH urned to normal but the serum bicarbonate level mained low This must have been due to a fall in the tial pressure of carbon dioxide in the blood (pCO_2) duced by respiratory compensation for the metabolic dosis. Nadell commented that pulmonary dissipation carbon dioxide seemed to be more effective after the ministration of acetazoleamide but the mechanism s obscure

Some criticism of this argument might be advanced spiratory acidosis the respiratory centre is already tively insensitive to the stimulus of a high pCO_2 ventilatory function of the lungs is so impaired that olar loss of carbon dioxide cannot be significantly eased despite additional stimulation of the respiratory tre (Wilson et al. 1954 Cohn et al 1954) and urinary of bicarbonate in response to the administration of acetazoleamide would tend to alter the ratio of serum bicarbonate to pCO_2, with a fall in pH which is potentially harmful to a patient who is already acidotic

Despite these theoretical objections we have given acetazoleamide to 3 patients with acute respiratory acidosis in the hope of preventing or relieving carbon dioxide narcosis. The patients all had chronic bronchitis emphysema and pulmonary heart-disease and their symptoms had been severely aggravated by acute respiratory infection. Striking biochemical changes took place in all the patients after the administration of acetazoleamide but no clinical improvement was noted Judged clinically the condition of the 1st patient was deteriorating before acetazoleamide was given the drug did not influence the course of the disease and the patient died In the 2nd patient the administration of acetazoleamide was immediately followed by much clinical deterioration a rapid downhill course ending in death The 3rd patient showed an alarming deterioration of the clinical condition after a single dose of acetazoleamide but improved when the drug was withheld

Case reports

Case 1—A woman aged 59 was admitted to hospital with a severe acute respiratory infection She had chronic bronchitis of five years duration, and this was now accompanied by emphysema and pulmonary heart-disease On admission she was pyrexial, dyspnoeic and cyanosed but conscious and rational.

Treatment and Course—She was treated with penicillin digitalis, and mersalyl and oxygen was given in small amount by nasal catheter with relief of cyanosis. Next day her general condition gradually deteriorated and she became comatose Her optic fundi showed gross distension and tortuosity of veins and congestion of the optic discs. Her serum bicarbonate level was 37 8 m.eq per litre and her serum urea level was raised but her serum potassium level was normal and remained so throughout the illness. She was given acetazoleamide 500 mg on the day after admission and the same dose was given daily for the next three days, and then every second day for three more doses. Eighteen hours after the first dose of acetazoleamide the serum bicarbonate level had fallen to 29 7 m.eq per litre but no clinical improvement was noted The serum bicarbonate level in the next ten days ranged from 32 4 to 41 8 m.eq per litre Oxygen therapy was continued by intermittent use of the oxygen tent and oxytetracycline was given The patient remained critically ill, with pyrexia dyspnoea and drowsiness, and four weeks after admission she lapsed into coma and died

Necropsy showed chronic bronchitis, emphysema recent bronchopneumonia right ventricular enlargement and congestive cardiac failure

Case 2—A woman aged 63 with nine years history of chronic bronchitis, was admitted to hospital with an acute exacerbation of pulmonary heart disease following an infection of her upper respiratory tract On admission she was cyanosed and dyspnoeic but conscious and rational

Treatment and Course—Penicillin and digitalis were administered but oxygen was at first withheld On the day after admission the serum bicarbonate level was 36 0 m.eq per litre The optic fundi showed dilatation and tortuosity of the veins, and the discs were slightly swollen. Oxygen therapy was started by nasal catheter and acetazoleamide 500 mg was given. Twenty four hours later the serum bicarbonate level had fallen to 32 4 m eq per litre and in that period the patient excreted 705 ml of urine containing 31 5 m.eq of bicarbonate On the second day after admission the patient became drowsy and confused and was placed in an oxygen tent She was given acetazoleamide 500 mg twice on that day and once more on the third day the serum bicarbonate level then having risen again to 30·0 m eq per litre The serum potassium level was normal Her condition rapidly deteriorated the drowsiness deepened into coma and she died on the third day after admission

Necropsy showed chronic bronchitis and recent pneumonic lesion fatty infiltration of and enlargement of the right ventricle cerebral oedema but no local lesion in the

Case 3—A woman aged 60 with chronic bronchitis with emphysema a

disease, was moderately ill when admitted for treatment of an acute respiratory infection.

Treatment and Progress —She improved under treatment with penicillin, digitalis, and oxygen given by nasal catheter Her serum bicarbonate level on admission was 49 5 m eq per litre, the level fell to 38 3 m eq per litre next day, but rose on the third day to 40 5 m eq per litre Acetazoleamide 500 mg was given on the third day In the next twenty four hours the patient excreted 1055 ml of urine containing 100 m.eq of bicarbonate, and the serum-bicarbonate level fell to 36 9 m eq per litre No more acetazoleamide was given, but renal excretion of bicarbonate continued for two more days, a further 62 m.eq of bicarbonate being excreted. This was accompanied by a further fall in serum bicarbonate level to 34 2 m eq per litre and 30 6 m eq per litre two and three days respectively after the administration of acetazoleamide Twenty four hours after the acetazoleamide had been given there was an unexpected serious deterioration in the patient's clinical condition respiration became shallow, cyanosis increased, and she became extremely drowsy She was placed in an oxygen tent, where she remained drowsy, confused, and breathless for two days, and then gradually improved During this time the physical signs in the chest were unchanged, the retinal veins were tortuous and congested, but there was no papillœdema, and the serum potassium level was normal Oxygen therapy was discontinued after three days, and the patient eventually made a good recovery The serum bicarbonate level was estimated every second day in the next week as 38 7, 32 0, and 37 8 m.eq per litre

Discussion

The clinical deterioration in these 3 patients depended on a combination of toxæmia, hypoxia, and retention of carbon dioxide Toxæmia played an important part in case 1, but in the 2 other patients the infection responded initially to treatment with an antibiotic Anoxia was present in all the patients, and our policy was to relieve this gradually, following the advice of Simpson (1954) by giving oxygen at first by nasal catheter at a rate of flow of 2–4 litres a minute, and only later transferring the patients to an oxygen tent Retention of carbon dioxide was probably a major factor leading to deterioration, and oxygen therapy may have contributed to this

In any attempt to measure the effects of retention of carbon dioxide the relevant physiological observations are the alveolar concentration of carbon dioxide and the pH of the serum, from which can be determined the pCO_2 It is unfortunate that it was impossible to obtain these measurements in our patients The serum bicarbonate level gave no indication of the clinical condition Case 2 was very much more ill, with an initial serum-bicarbonate level of 36 0 m eq per litre, than was case 3, whose serum-bicarbonate level on admission was 49 5 m eq per litre Considerable fluctuations in the serum-biocarbonate level in case 3 have already been noted, these were independent of treatment and unrelated to the clinical condition There seems to be no doubt, however, that acetazoleamide caused an initial fall in the serum-bicarbonate level in all 3 patients The lack of clinical improvement suggests that the fall of the serum-bicarbonate level was not accompanied by a corresponding fall in pCO_2, presumably because of pulmonary insufficiency We cannot offer direct proof of this hypothesis, but, if it is true, the initial effect of acetazoleamide in these patients was to alter the ratio of pCO_2 to serum-bicarbonate in such a way as to cause a potentially dangerous fall in serum pH There is ample evidence that this happens when acetazoleamide is administered to patients with normal respiratory function (e g, Nadell 1953, Counihan et al 1954), and Simpson has demonstrated that the same mechanism operated in his own cases of respiratory acidosis The rapid return of the serum bicarbonate level to its initial high value in cases 1 and 2 was not accompanied by improvement, possibly bec respiratory centre remained adversely affected by the persistently high pCO_2, or as a result of temporary lowering of pH

We conclude that in these 3 cases of acute r acidosis accompanied by pulmonary infection acetaz amide was of no value, and that its property of prom ing renal excretion of bicarbonate may have been har to the patients

Summary

The carbonic anhydrase inhibitor, acetazoleamide, given to 3 patients with acute exacerbation of respiratory acidosis

Increased urinary excretion of bicarbonate and of the serum bicarbonate level resulted

In all 3 cases there was clinical deterioration 2 patients died, and the 3rd recovered when the amide was withheld

It is concluded that acetazoleamide may be de in acute respiratory acidosis

We wish to thank Prof Stanley Alstead and Dr J Macarthur, under whose care these patients were treated, their advice and encouragement, and Dr J W and Dr A W Mollison for the biochemical estimations.

TUBERCULIN AND LEPROMIN SENSITIVITY IN THE SOUTH AFRIC BANTU

A PILOT SURVEY

S W A Kuper
M B Rand, D P H., D T M & H, D C.P
CLINICAL PATHOLOGIST, BROMPTON HOSPITAL, LOND

It has often been stated that skin sensitivit tuberculin and lepromin are correlated, and it has inferred that this reflects an immunological relati (Chaussinand 1950, Fernandez 1943, Lowe and Mc 1953b)

The significance of skin sensitivity to lepromin clearly established, and this sensitivity is used as an to classification and prognosis in leprosy rather than a means of diagnosis Most patients with lepromat leprosy are relatively insensitive to lepromin, where those with tuberculoid leprosy are said to show a m marked allergic response, which may be either a "tub culin like" reaction at forty-eight to seventy two ho (the Fernandez test) or an indurated nodule from two five weeks after the inoculation The two types of rea tion are said to parallel one another in the individ case (Fernandez 1940, Lowe and McNulty 1953b), but th method of preparation of the antigen determines wheth the early or the late reaction is the greater Much of th published material on this subject is largely speculati but a good deal of the data appears to support the the that the degree of correspondence between tuberc and lepromin reactions is far greater than could accounted for if the two forms of sensitivity were com pletely unrelated

I describe here an attempt to elucidate some of the problems by tests on South African Bantu patients controls Patients with pulmonary tuberculosis others with leprosy were investigated together with apparently healthy adults The numbers tested were

TABLE I—MEAN SIZES OF REACTIONS

Group	No of persons	Mean transverse diameter of reaction (standard error of mean)					
		Tuberculin at 48 hr	Nil reactors	Lepromin at 48 hr	Nil reactors	Lepromin at 4 weeks	Nil reactors

berculoid leprosy (female children)	6	3 2 mm (*1 44*)	2	10 2 mm. (*3 12*)		6·2 mm (*2 36*)	

This table represents the mean transverse diameters of reactions recorded in all the groups of patients It lists the reactions to tuber- in at 48 hours, and to lepromin at 48 hours and at 4 weeks The standard error of the mean is included in parentheses after each result e numbers of subjects in whom no reaction was found are given in a separate column, but they are included in the figures of totals for h group

ge but it was hoped that this disadvantage would be ercome by careful standardisation of methods (Guld d Rud 1953 Meyer et al 1951)

Methods

The persons tested were divided into three categories

Group 1—Patients with pulmonary tuberculosis (37 adult les)

Group 2—Patients with leprosy (102 mostly adults but me children aged 10–16 years)

Group 3— Controls (114 adult males)

The patients with tuberculosis were in hospital during e trial. They showed no obvious evidence of leprosy diographs of the chest were characteristic of pulmon y tuberculosis, and tubercle bacilli had been isolated m the sputum in about 90% of the cases

The leprosy patients were all being treated in an stitution during the trial, and radiological examination thin the preceding few months showed no evidence of lmonary tuberculosis The clinical diagnosis of leprosy d in all cases been substantiated by examination of ne smears and the type of leprosy was classified by e experienced permanent medical staff of the institute ts were made in 52 patients with lepromatous leprosy d 50 with tuberculoid leprosy

The controls consisted entirely of adult industrial ployees working in a soap factory and resident in the y Within a few weeks of the start of the trial they were diographed to exclude anyone with a shadow suggesting lmonary tuberculosis No obvious evidence of leprosy s seen in any member of the group

So far as is known none of the persons in any group d ever received B C G vaccine

chniques

Dried lepromin of the Dharmendra type was prepared by . N Figueredo of the Acworth Leprosy Home Bombay his antigen produces more prominent early reactions than layed ones, and is therefore more strictly comparable to berculin than is the Mitsuda type of antigen. The lepromin s finally suspended in half the recommended volume of line solution to reduce the volume of the intradermal injec n from 0·2 ml to 0 1 ml It was sealed in ampoules in reat Britain and was used within a month of the date of lling

Tuberculin was used in the form of purified protein rivative It was dissolved and diluted so that 0 1 ml ntained 5 tuberculin units. It was thought that this small se of tuberculin would detect only high specific degrees of sitivity (Palmer and Bates 1952 Palmer 1953) Tablets re dissolved freshly for each session of inoculations.

Syringes were of the all glass tuberculin type All the ringes were new and each was used for only one inoculating ssion to prevent possible transference of antigen Only new edles were used and they were discarded at the end of each ssion. The syringes were examined for leakage and the iteria recommended by Guld and Rud (1953) for field trials re adopted 48 syringes were tested by their method but ly – satisfied their requirements. Fortunately it was found that a light smear of silicone oil applied to the barrel of the syringe reduced leakage to such a degree that 37 out of 48 syringes could be used Several intradermal inoculations of water made with these syringes in hospital staff produced no evidence of sensitivity to the silicone oil

Procedure

All the inoculations and readings of results were made by me to minimise individual variations of judgment (Meyer et al 1951) All the controls were inoculated on one day and all the patients with leprosy and tuberculosis on another The injections were made in the skin of the ventral surface of the forearm about half way between the wrist and elbow The volume inoculated was in all cases 0 1 ml administered intradermally so as to raise a distinct bleb in the skin Lepromin was injected into the left arm and tuberculin into the right each patient received the two inoculations within a few minutes

Because of skin pigmentation in the patients no attempt was made to delimit areas of erythema Measurements were made of the induration produced the edges of the areas were carefully defined, and the transverse diameters measured in millimetres with a transparent rule The site of inoculation of the tuberculin was examined after forty eight hours that of the lepromin inoculation was examined at forty eight hours, and after one two three, four five and six weeks

Results

Table I shows that the tuberculous and the control groups consisted entirely of adult males, but the leprosy patients included adults and children of both sexes Distinct variations are apparent between males and females and adults and children so the results are recorded under separate headings In figs 1–3 the sexes and ages are not separated

The numbers of subjects vary slightly from table to table depending on the numbers available for measurement on the day in question The controls for example were 114 after forty eight hours but only 105 of these presented themselves for examination on the twenty eighth day

The results may be examined in one of two ways In the first place evidence may be sought of any correlation between skin sensitivities to lepromin and tuberculin This is best elicited statistically by the examination of product moment correlations but dot diagrams give an approximate picture of the relationships (fig 1) (The product moment correlation takes into account the sizes of reactions in each patient and may be regarded as a statistic summarising the degree of association exhibited in the dot diagrams) In this investigation no correlation between the two forms of sensitivity was found in 105 controls nor was there any evidence of association in the 86 adults with leprosy In the 53 patients with pulmonary tuberculosis, however a definite positive correlation was obtained (product moment correlation=0·40 ** The chance of this being a random result is less

1000) * A small positive correlation was also found between the tuberculin reactions at forty-eight hours, and the lepromin reactions at twenty-eight days It is smaller than the forty-eight-hour correlation, and possibly merely residual from it The need for caution in assessing the importance of the observation is emphasised by the failure to find any correlation between the tuberculin and lepromin reactions in the other two test groups

The results may also be examined in another way If the suggestion is accurate that there are antigens common to the tubercle and leprosy bacilli, one might expect to find skin hypersensitivity in each of the two diseases, to the causal organism of the other, or to products derived from it Patients with tuberculosis might react strongly to lepromin injection, and patients with leprosy to tuberculin This could never be more than an approximation, however, for lepromin hypersensitivity is far less regular, even in leprosy, than is tuberculin sensitivity in tuberculosis

Skin reactions to lepromin (examined at forty-eight hours) were compared in healthy adults and in patients with pulmonary tuberculosis The latter were found to be significantly more sensitive to lepromin than the controls (mean for tuberculous patients 7 4 mm , and for controls 3 8 mm), and the same trend is evident in histograms (fig 3) †

Conversely, skin reactions to tuberculin were compared in healthy adults and in patients with leprosy The picture is rather complex Patients with tub leprosy appear to react less strongly to tuberculin th do the normal controls (fig 2) This difference is siderably reduced, however, if the male patients are compared with the controls, all of whom were ma The mean size of reactions in the male patients wi tuberculoid leprosy was 10 6 mm , and that in the nor controls 12 5 mm The difference is not significant Th female leprosy patients cannot properly be compa with the male controls In lepromatous leprosy, th measurements are widely scattered , the mean reacti however, are significantly greater (males, mean=1 mm) despite the fact that 12 members of this gro showed no reactions at all to tuberculin (fig 2) The was a very high degree of tuberculin sensitivity in som members of this group

Much of the published work on skin reactions in lepros records the observed reactions in terms of an arbitrar scale of "positive" and "negative" reactors. So

---

* *Validity of Tests Used*—In comparing mean sizes of reactions between the various groups, and in assessing the significance of correlation between the reactions obtained to the two antigens, statistical tests were used which depend for their validity on the normal (gaussian) distribution of the measurements Evidently this type of distribution is not fulfilled, so the tests must be regarded as having only an approximate significance

† In figs 2 and 3 data relating to the forty eight hour tubercu and lepromin reactions are shown as histograms. The gr intervals have been judiciously chosen to conceal th tendency towards recording even numbers of millimetr particularly in measuring the relatively large reacti Superimposed on the histograms of the controls are th fitted logarithmic normal distributions, reached disregarding the information on reaction diameters than some arbitrarily selected level—8 mm in the c of tuberculin reactions, 1 5 mm in the case of lepro reactions (Hald 1952a and b)

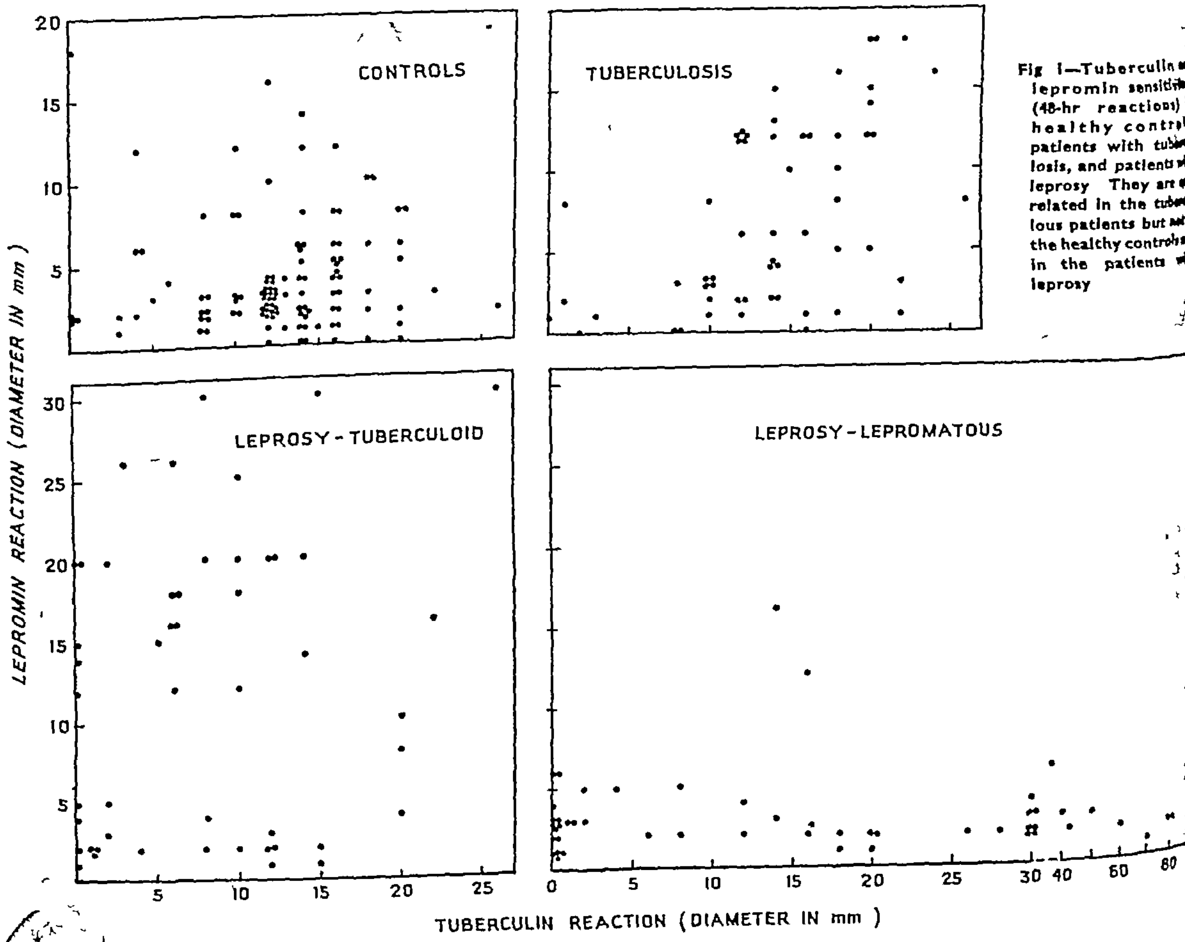

Fig 1—Tuberculin lepromin sensiti (48-hr reactions) healthy controls, patients with tu losis, and patients leprosy They are related in the tu lous patients but the healthy controls in the patients leprosy

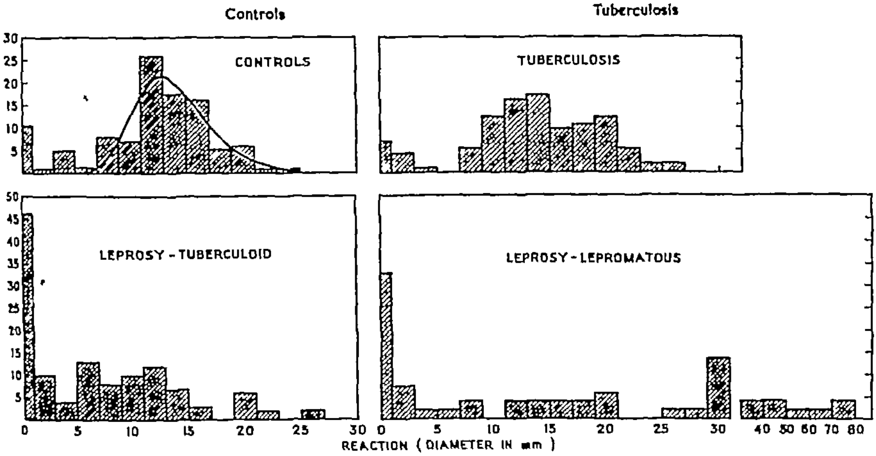

Fig 2—Tuberculin sensitivities (48-hr reactions) in healthy controls patients with tuberculosis and patients with leprosy

ndards provide a useful rule of thumb for clinical rposes but their adoption in a survey of immunological actions leads to the discarding of a great deal of the formation (Edwards et al 1953) This trial records the tual observed measurements but it is possible to divide e readings at any desired level to facilitate comparison th results published only in terms of 'positives' and negatives' Such comparison is obviously of limited lue unless conditions in the two surveys are very nilar

Table II represents the results of this trial analysed the above lines Tuberculin reactions with a diameter 6 mm or more are corded as positive lepromin reac ons 6–10 mm. in ameter as 'doubtful' and 11 mm or ore as positive hese criteria for rty eight hour promin reactions ere recommended y the International eprosy Congress in adrid 1953) In ble II doubtful d "positive" results re grouped together y this method of nalysis the results are gnificant only if it an be shown that he likelihood of the bserved distributions aving occurred by hance is less than /20 This level of gnificance was not ttained by any of the roups in this series.

Despite the possi ility of errors in lassification between he types of leprosy he results for the two groups are not 'combined' for any of the investigations This precaution was deemed necessary because of the widely divergent patterns of skin sensitivity in the two forms of leprosy It may be argued that the clinical classification was possibly biased by the results of earlier lepromin reactions but the pictures of tuberculin sensitivity in the two forms of leprosy are so widely different that it appears to reduce to a minimum the likelihood of widespread misclassification of the type of disease.

Early and Late Lepromin Reactions

The forty-eight-hour lepromin reaction is not significantly different in controls and in patients with lepro

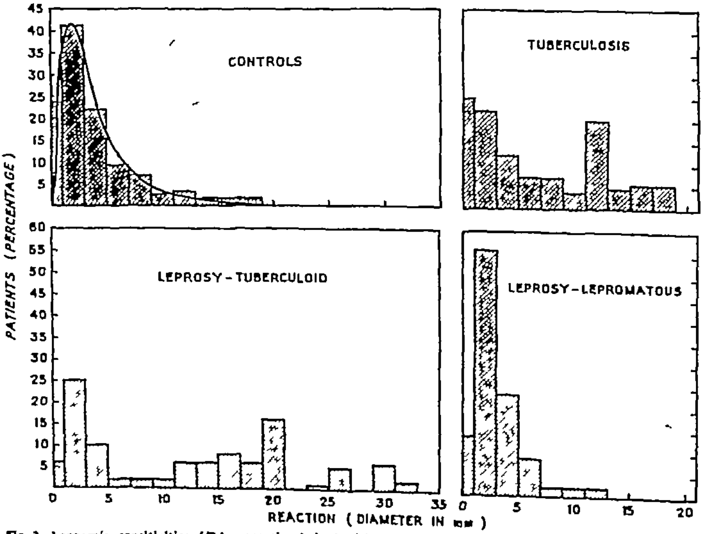

Fig. 3—Lepromin sensitivities (48-hr reactions) in healthy controls, patients with tuberculosis and patients with leprosy

TABLE II—NUMBERS OF "POSITIVE" AND "NEGATIVE" REACTORS

Group	Tuberculin negative (0–5 mm)		Tuberculin-positive (≥6 mm)		Total
	Lepromin negative (0–5 mm)	Lepromin positive or doubtful (≥6 mm)	Lepromin negative	Lepromin positive or doubtful	
Controls	8	4	80	22	114
Tuberculosis	4	1	24	28	57
Lepromatous leprosy (males)	12	1	17	3	33
Lepromatous leprosy (females)	6	2	11	0	19
Tuberculoid leprosy (males),	3	4	7	18	32
Tuberculoid leprosy (females)	7	4	3	4	18

The subjects tested are grouped in this table into "positive" and "negative" reactors, in terms of arbitrary scales, as defined.

matous leprosy, but late lepromin reactions tend to be smaller in the latter This difference may be due to inaccuracy in measuring the very small reactions In males with lepromatous leprosy there is a 90% probability that the mean twenty-eight day reaction size lies between 0 9 mm and 2 1 mm, whereas for controls at twenty-eight days the equivalent figures are 3 4 mm and 3 9 mm (table I) In adult males with tuberculoid leprosy the late lepromin reaction, as would be expected, is substantially greater than that seen in controls (mean twenty-eight day lepromin reaction 4 8–9 6 mm)

Skin reactions to both antigens in males with tuberculoid leprosy are usually larger than in females (table I) This is particularly true of the forty eight-hour tuberculin reaction This sex difference is not so clear cut in lepromatous leprosy, unless one omits the 12 males and 1 female showing no measurable reactions to tuberculin, and the 13 males and 7 females showing no reaction to lepromin at twenty eight days If a measurable reaction does result, the mean values are larger in males At twenty-eight days the trend is still present but less striking

There is some correlation between forty eight hour and twenty-eight-day lepromin reactions, but, except in the case of tuberculoid leprosy, it is smaller than might be expected (Fernandez 1940) The two reactions were not always parallel, and an appreciable late reaction was usually (but not always) preceded by a large early reaction In view of the type of antigen used, this feature is perhaps not surprising, and no emphasis can be placed on the late readings

It might prove useful to investigate late lepromin reactions on the basis of histological appearances in biopsy material from the site of inoculation This technique has been found to increase the diagnostic value of reactions to Nickerson-Kveim antigen in sarcoidosis (Siltzbach and Ehrlich 1954)

Discussion

In an investigation of this kind there are several difficulties in interpreting the results It has been claimed that tuberculin and lepromin sensitivities are positively correlated, and on the basis of this observation an immunological relationship between tuberculosis and leprosy has been postulated Such a thesis would be more easily tenable if the sensitivities involved indicated immunity in their respective diseases, but tuberculin sensitivity does not imply immunity to tuberculosis, and significant lepromin sensitivity is seen mainly, if not [illegible], in the tuberculoid form of leprosy The re[illegible] be regarded as immunological factors only in so far as they reflect the capacity of the host's tissues to react to the corresponding antigens

In tuberculoid leprosy, skin sensitivity to lepromin is usually high, the disease itself is mild and self limiting, suggesting a high resistance to leprosy bacilli From these observations it appears to have been inferred that high lepromin sensitivity is closely associated with high resistance, and, therefore, the production of lepromin sensitivity in uninfected people might protect them against infection For this purpose, B C G vaccination has been advocated Many workers have recorded increases in lepromin as well as tuberculin sensitivities after the administration of B C G vaccine to healthy subjects A large proportion of people with "negative" reactions to lepromin are stated to become "positive" after this measure (de Souza Campos 1953, Ferna 1943, 1951, Kocsard and Sagher 1953, Lowe and Mc 1953a) This observation is particularly intere Cochrane (1955) states that lepromin "conversion" i seen in patients with lepromatous leprosy who tuberculosis

The present investigation is not concerned with relationship of immunity and skin sensitivity, but with the possibility of there being some correlation between the sensitivities induced in man by infection with tubercle and with leprosy bacilli In this pilot study the degree of correlation established between tuberculin and lepromin sensitivities was small, and was found only among the patients with pulmonary tuberculosis, the smallest of the three groups tested in the trial Furthermore the tuberculous patients showed a greater degree of sensitivity to lepromin than did the controls—though this may be merely a consequence of the former correlation In lepromatous leprosy, where lepromin sensitivity is slight or absent, a small proportion of the patients showed an intense degree of sensitivity to tuberculin. When these were excluded the two main groups of leprosy patients did not show greater tuberculin sensitivity than the controls

In view of these findings there seems to be no simple and direct relationship between tuberculin and lepromin sensitivities However, the observations in patients with tuberculosis and lepromatous leprosy suggest the existence of a relationship of some kind

Summary

A pilot survey was made to investigate correlation between tuberculin and lepromin sensitivities in the South African Bantu

Three test groups were selected for the trial 10 patients with leprosy, 57 patients with pulmonary tuberculosis, and 114 healthy controls

In the controls and in the patients with leprosy no correlation could be established between lepromin and tuberculin sensitivities In the patients with pulmonary tuberculosis, however, a positive correlation was found. Furthermore these tuberculous patients showed a greater degree of sensitivity to lepromin than did the controls

A small proportion of the patients with lepromatous leprosy showed a very high degree of sensitivity to tuberculin

I am greatly indebted to the medical superintendents and staff of the Westfort Institution, Pretoria, and the Waterval Hospital, Johannesburg, for facilities and willing assistance, to the British Tuberculosis Association for providing the lepromin, and to Dr R G Cochrane, through whose kind services it was made available, to Mr B Benjamin for his advice in planning the trial and for scrutinising the early results, to Mr P M Payne for his exhaustive statistical analyses of the complete findings, and to the Board of Governors of the Brompton Hospital for allowing a period of study leave during which this work was done Lastly, I should like to thank Dr R W Riddell and Dr J R Bignall, of the Brompton Hospital, for their advice, help, and encouragement

TRAUMATIC RUPTURE OF DIAPHRAGM WITH HERNIATION OF ABDOMINAL VISCERA

K. K. SINHA
F.R.C.S.

[illegible]

Indirect violence is one of the rarer causes of traumatic rupture of the diaphragm, and in most recorded cases the patient sustained gross injury to abdominal viscera. In the case described here the only abdominal organ to be injured was the spleen.

A woman, aged 45, was admitted to hospital a few hours after a car accident in which she had been thrown on to her left side and had felt a sudden snap all over the left side of her chest.

On admission her pulse-rate was 90 per min., blood pressure 120/90 mm. Hg, respirations 20 per min. There was no cyanosis or evidence of respiratory distress, though she complained of pain in the left side of her chest. Bowel sounds were audible over the left hemithorax.

Radiography of the chest revealed fractures of the upper [illegible] ribs on the left side. The left lung seemed to be collapsed and the diaphragm appeared unusually high; the gastric shadow could be seen as high as the fifth left intercostal space (fig 1). Barium-swallow showed considerable distortion of the oesophagus and confirmed the presence of stomach high up in the thoracic cavity (fig 2).

Diagnosis.—The absence of respiratory distress was difficult to explain in view of the radiographically and clinically demonstrable collapse of the left lung. The problem was whether it was a case of congenital high diaphragm or a tear of the diaphragm with herniation of the bowel and collapse of the lung. The history of trauma along with the radiographic findings suggested a diagnosis of traumatic rupture of the diaphragm.

Progress.—The patient's general condition remained quite satisfactory. She had no difficulty in taking food, and the bowels continued to act normally for two days after admission. On the third day she started to vomit, and screening showed the beginning of [illegible]. She was [illegible] in the thorax [illegible]

Operation.—Thoracotomy was [illegible] through the bed of the [illegible]. Inside the left pleural cavity the spleen, stomach, transverse colon, [illegible] were found. On the left side there was a large tear [illegible] backwards, where the [illegible] the muscular portion. The spleen was [illegible] but there was no [illegible] to suggest [illegible] bleeding. But on opening the chest profuse [illegible] began and splenectomy had to be done. The stomach was returned to the abdomen and the [illegible] was [illegible]. The diaphragm was repaired with interrupted [illegible] sutures, and after the abdominal and thoracic [illegible] had been evacuated the lung expanded without any difficulty [illegible] by the anaesthetist.

Fig. 1—Radiograph of chest showing high gastric shadow, collapsed left lung, and fractured ribs.

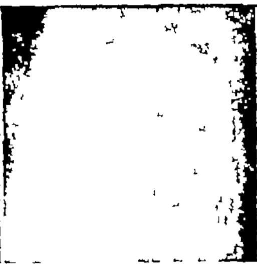

Fig 2—Barium-swallow: oesophagus distorted and the stomach high in the thoracic cavity.

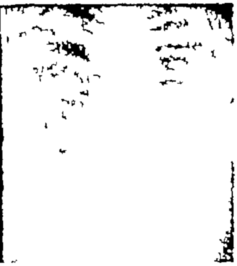

Fig 3—Postoperative appearance: left lung re-expanded.

Progress.—Postoperative progress was uneventful, and bowel sounds returned within twenty-four hours. Oral fluids were begun within thirty-six hours of operation. On the tenth day after operation the blood-pressure was 120/80 mm. Hg, and the apex-beat had returned to the normal position. There was no abdominal distension. Breath sounds were clearly audible at the left base though slightly diminished compared with the opposite side. Radiography showed satisfactory expansion and functioning of the left lung (fig 3).

Noteworthy features in this case were that: (1) the patient's general condition remained good despite collapse of one lung and herniation of a large amount of bowel; (2) there was no evidence of shock at the time of admission; and (3) the ruptured spleen bled only when the chest was opened.

DIAPHRAGMATIC HERNIA FOLLOWING INJURY

F. A. HAMDI
M.B. Alexandria, Ph.D. Edin.

D. K. STURDY
M.B. Lond.

REGISTRARS, DEPARTMENT OF NEUROSURGERY, MORRISTON HOSPITAL, SWANSEA

It is known that severe crushing injuries to the abdomen and chest may be responsible for rupture of the diaphragm with subsequent development of diaphragmatic hernia. Of 7 cases reported by Evans and Simpson (1950) 5 were due to severe crushing injury to the abdomen, 1 sustained bruising of the chest wall, and none had fractured ribs. Evans and Simpson suggested that the mechanism of the injury to the diaphragm was in the nature of an explosive rupture due to sudden increase in intra-abdominal pressure.

The case presented here illustrates how herniation of abdominal contents into the thoracic cavity revealed itself as an acute abdomino-thoracic emergency twenty-four hours after the injury.

Case report

A man, aged 40, was admitted semiconscious to the neurosurgical unit at 11.30 P.M. on May 8, 1951, having been knocked down by a motor-car an hour previously. Immediately after the accident he had been given morphine gr. [illegible] by a [illegible] practitioner.

On admission he was easily roused but did not [illegible]. He had a laceration over the right eye [illegible] skull showed a comminuted fra

Dr. Robert Heilig
S. M. S. Medical College
33355
JAIPUR

right superior and lateral orbital margins and a depressed fracture of the outer wall of the frontal sinus in the midline There were no abnormal neurological signs on examination nor any signs of shock, the pulse rate being 68, respirations 20 per minute, and the blood-pressure 150/80 mm Hg There were no obvious signs of injury to the abdomen or the chest The patient had passed clear urine since the injury

Operation —At 10 A M, next day, under general anæsthesia, the supraorbital wound was cleaned and excised, the fracture involving the orbital margins was reduced, and the wound was closed in layers

Postoperative Course —On his return to the ward the patient became very restless and began to vomit what appeared to be altered blood Later in the day he complained of pain in the epigastrium and breathlessness There was no shoulder pain The pulse rate had increased rapidly to 128 and respirations to 40 per minute, while the blood pressure had dropped to 90/60 mm Hg

On examination, the patient was extremely pale and sweating profusely, with anxious facies, and lying on his right side with his knees flexed The apex beat was 2½ inches from the midline in the fifth left intercostal space The heart sounds were normal The left side of the chest was immobile on respiration and dull on percussion as high as the third left intercostal space anteriorly There was complete absence of breath sounds over this area, and no adventitious sounds were heard There was good air entry in the right lung The abdomen moved normally on respiration, there was tenderness and guarding over the left hypochondrium and epigastrium, percussion revealed a normal area of liver dullness, and bowel sounds were absent Rectal examination revealed no abnormality A provisional diagnosis of ruptured diaphragm with hæmothorax was made, and in view of the rapidly deteriorating condition of the patient immediate operation was considered advisable

Second Operation —The abdomen was explored through a left paramedian incision. There was no free fluid or blood in the peritoneal cavity A large oblique tear, 5 inches long, was felt in the left cupola of the diaphragm The region of the left kidney and splenic flexure of the colon was contused The stomach and spleen had herniated into the left pleural cavity through the tear in the diaphragm A thoracotomy with resection of the left ninth rib was next performed, this rib was found to be fractured in the mid axillary line The stomach was much dilated and thin walled, with numerous subserous hæmorrhages As it could not be reduced through the diaphragmatic tear, its contents were aspirated, three pints of coffee coloured fluid being recovered The stomach and spleen were then returned to the abdominal cavity, and the tear in the diaphragm was sutured with 'Mersilene' The thoracotomy incision was closed with drainage of the left pleural cavity, and the laparotomy incision was closed without drainage Blood (2 pints) was given intravenously during the operation

Recovery was uneventful Daily radiography of the chest showed a completely expanded left lung, with a little effusion of fluid at the left base after the fourth day this effusion gradually resolved A month later a barium meal showed no evidence of intrathoracic herniation, and radiography of the chest revealed complete expansion of the lungs

Comments

This case is of interest because the abdominal contents must have herniated into the thorax after the administration of the first anæsthetic for suturing the supraorbital margin The stomach presented the picture of acute dilatation Most of the published cases of traumatic hernia have developed insidiously, appearing from a few days to many weeks after the original injury Frequently the diaphragmatic lesion had been overshadowed by more serious intrathoracic or intra abdominal complications

We have been unable to find any reference to the enormous gastric dilatation noted in the present case It seems likely that, at the moment of injury, the diaphragm ruptured explosively owing to increased intra-abdominal pressure Later on, during the induction of anæsthesia and possibly associated with straining, the tear became large enough to allow herniation of the stomach and spleen into the thorax, and the constriction at the hernial orifice caused great dilatation of the herniated stomach

This [illegible] illustrates the importance of making a [illegible]ical examination in cases of injury to the head, not only at the time of admission but also dur the ensuing stages of return to consciousness

We are indebted to Mr Norman Whalley for permission publish this report

Preliminary Communication

HYALINE MEMBRANE IN THE LUNGS OF THE NEWBORN

IN recent years much work has been done to elucid the nature, source, and cause of hyaline membrane the lungs of newborn infants Farber and Wilson[1] showed that similar membrane is sometimes formed other conditions, and Farber[2] later demonstrated th œdema and membrane could be produced in rabbits b bilateral mid cervical vagotomy Others[3–6] have a shown that various experimental procedures may prod a similar disease pattern in the lungs of animals, and it generally agreed that a number of agents and proces may lead by one or more mechanisms to a comm histopathological finding

Histochemical analyses of the membranes[3–6] as foun in premature babies and in experimental animals hav established the presence of a polysaccharide aldehy Wagner,[7] who has carried this a stage further, belie that the membrane contains mucoprotein and that it formed from endogenous mucus derived from the na pharynx, buccal cavity, and bronchial tree of the inf Other observers[3] have been unable to demonstrate muc in hyaline membranes by histochemical methods, a this does not surprise us, since we have found that th epithelium of the respiratory bronchioles is muc negative, and that the only mucus secreting gla present are sparse subepithelial acini Very rece Gilmer and Hand[8] concluded from morphological stud that the membranes are endogenous, and, by th application of two methods hitherto not used in the st of this disease, we ourselves have come to the s conclusion Our methods seem to reveal both the nat and source of the membranes

Using frozen sections of formalin-fixed material, applied the Lepehne Pickworth benzidine nitropru peroxide technique[9] By this method the erythroc were stained an intense blue black as expected, but th hyaline membrane took on a uniform rich royal bl colour The occasional blue black red cell could be eas identified as an entirely distinct body in the membra It was further noted that the epithelium of the respirato bronchioles and alveolar ducts showed a rich royal bl granularity, and in some cases this granularity was intense that the epithelial cells were seen as a unifor royal-blue The intensity of this royal blue staining o the membranes and epithelium was somewhat less material which had been in formol saline for 3–5 month

At this stage we realised that we were dealing wi either organic iron or peroxidase enzyme, or both We then found that previous treatment with 5% sodium cyanide, or 5% sodium azide, or steaming for 5 minutes in each case reduced the intensity of the royal blu staining, but did not abolish it However, we noted als that lengthy treatment of frozen sections by these method abolished the staining reactions by removal of the membranes and granules From these observations ar m the fact that the staining intensity was diminished – material which had been fixed for a long time in mol saline, we concluded that the reaction was due rtly to enzyme but mainly to organic iron

[9] Lillie R D Histopathologic Technic Philadelphia 194 p 119

To test these conclusions we applied the Nadi ction to frozen sections by placing these in 1% alpha phthol (alcoholic) for 5 minutes and then for 5 minutes 1% aqueous dimethyl para phenylene diamine By s technique the hyaline membranes and granules in e respiratory bronchioles were stained a purplish blue the indophenol blue, the staining of the red blood-cells ing more intense but of the same colour Prior treat ent of the sections with cyanide, &c. was found to minish but not abolish the staining reaction

The lungs of several controls were examined by both chniques, and from these it was apparent that the nsity of the specifically staining granules in the spiratory bronchiolar epithelium was inversely pro ortional to the gestation age and that it was greater in ematures dying of hyaline membrane disease than in mparable prematures not having this condition owever, the intensity of the granularity was much less very premature infants (less than 1200 g) Further was apparent that the specific granularity of the ithelia of the respiratory bronchioles and alveolar cts increased with respiration since it was virtually sent in lungs atelectatic from birth and in those of llborn infants The œdema fluid in adult cases of rebral trauma and in cases of bulbar poliomyelitis was nd to contain abundance of these specific granules enly scattered throughout the fluid and it was clearly ident that drying and condensation of such pulmonary dema fluid would lead to formation of a membrane hich would stain uniformly by the techniques used

It is very unlikely that these specific staining reactions the hyaline membranes are due to diffusion of material o the membrane In the first place the staining is o even for a diffusion phenomenon Secondly where uld this material come from except from the respiratory nchioles which we have shown to be laden with nules of the same staining reactions ? Hæmolysis as use is also unlikely, because the reactions were found cases with no pulmonary hæmorrhage and because a case of hæmorrhagic pulmonary disease of the new rn, where hæmolysis was evident in the presence of st red cells the picture was patchy and uneven ally we have found that the two reactions work ilarly and equally well in deep frozen unfixed lung ue from a case of hyaline membrane disease

It seems to us most likely that the common factor ponsible for the two reactions (Lepehne Pickworth d Nadi) is the cellular respiratory enzyme system tochrome-oxidase/cytochrome C It is indeed possible at respiratory enzymes are produced in the granules hich we have demonstrated in the epithelia of the piratory bronchioles and alveolar ducts and it is mpting to suppose that this enzyme system is an tive secretion of the epithelia An analogy may there to be drawn between infants developing hyaline embrane disease and the experimental rabbits of rber in that both probably suffer from an uncontrolled cretion of this enzyme system Further it is very obable that the actual hyaline membrane represents condensed and dried accumulation of this secretion, pecially as it is conceded that the only factor known modify the incidence and severity of this disease is gh humidity

We cannot at this stage be certain that the substance(s) ving rise to the reactions described here are cytochrome-idase/cytochrome-C since other metallic porphyrin otein complexes could be responsible for similar stochemical findings

Metabolic Factors and the Infectious Process

THE section of pathology met on April 26 under the chairmanship of Prof L P GARROD the president to hear Prof RENÉ DUBOS, of the Rockefeller Institute, New York discuss the Effects of Metabolic Factors on the Infectious Process

Professor Dubos described experiments by which the expectation of life of mice infected with tubercle bacilli and also with strains of staphylococci salmonella, and klebsiella could be shortened. He had found that the expectation decreased when animals were exposed to various stresses" before inoculation A number of different stresses had been used including the administration of thyroxine or dinitrophenol, in such doses as to inhibit the animal's normal weight gain, or of sodium citrate and α keto glutarate The simplest method however, was starvation for thirty-six hours before inoculation and this method had given the most striking results. The results after starvation could not be explained simply by calorie deprivation for low-calorie diets adequately varied in constitution, which reproduced the effects of starvation, did not decrease the animal s resistance moreover the effects were observed too soon and were too quickly cured for this to be likely Nor was it simply weight loss that produced the effect for mice fed on diets so low in protein that their normal weight gain was offset were normally resistant to infection Professor Dubos had also shown that the most effective way of lowering resistance was by starvation for forty eight hours before inoculation and that recovery was complete after forty-eight hours on the standard Sherman diet On the other hand when the mice were fed with a mixture containing adequate fat, carbohydrate minerals, and vitamins but with essential amino acids in place of protein the state of increased-susceptibility was indefinitely prolonged Normal resistance was not restored until a whole protein was added. Not all proteins were equally effective in this respect, and of those tested casein was the best

The results could be explained either by increased susceptibility of the animals to the bacterial toxins or by more rapid and extensive bacterial growth It had been found that, after thirty-six hours of fasting mice were more sensitive to endotoxins from gram negative organisms and to the recently isolated tuberculous toxin so that the LD_{50} was reduced to a half or a third of that for normal animals Starvation for forty-eight hours, followed by a diet low in protein would reduce the LD_{50} to a tenth But these comparatively small effects could not explain the observed change in susceptibility

In other experiments bacteria were injected intravenously in mice and later estimated quantitatively in various organs—with remarkable results Two groups had been studied : one had the standard Sherman diet (group 1) and the other had a diet low in protein and was then starved for forty eight hours (group 2) Both groups were *inoculated* with a dose of 10^6 Friedländer s bacillus (group III) and their organs examined quantitatively for bacteria ten hours later with the following results

	Spleen	*Liver*	*Blood*
Group 1	0 0 18	1 1 0	Sterile
Group 2	12–6000	10–50 000	+ + +

Similar results were obtained with other organisms—e.g staphylococci—and using other forms of stress, such as increased carbohydrate intake or thyroxine administration

Professor Dubos concluded that the effect of malnutrition was to impair the local bactericidal powers of tissues possibly through depression of the reticulo-endothelial system It has been shown (Berry and Mitchell) that if the Krebs cycle was poisoned the animal's resistance was likewise depressed Therefore it seemed that the observed change in susceptibility might be explained by (*a*) lack of cellular glycogen, or (*b*) decreased glycogenolytic activity by the cell, or (*c*) lowered levels of polycarboxylic acid in the tissues All these effects led to impaired clearing-power of the reticulo endothelial system, decreased bactericidal power of the tissues, and decreased resistance to bacterial toxins Impaired antibody formation could not be cited, for mice had no natural immunity to Friedländer's bacillus

Summing up, Professor Dubos made three points (1) susceptibility to infection in mice can change rapidly as a result of various stresses, (2) the effect is rapid in onset, and rapidly reversible, and (3) the factors concerned seem to be independent of those taking part in the host's normal physiological processes

Prof A A **Miles** discussed the vascular phenomena during the earliest stages of infection He had found that the local reaction to the subcutaneous inoculation of organisms could be abolished by adrenaline, and that if this was done survival of the inoculum was enhanced tenfold The effect could be obtained only if adrenaline was injected locally within four hours of the bacterial inoculum Similar results were observed when the complement was inhibited by 'Liquoid' When the experiments were repeated using the vole bacillus, adrenaline was found to have little effect, but liquoid greatly enhanced survival in the local lesions By using histamine or a globulin permeability factor the local lesion was reduced in size to that of one produced by a tenth of the inoculum in untreated animals

Dr D A **Long** spoke on hormone balance in allergy and immunity He emphasised the importance of choosing a laboratory animal which showed similar immune and allergic reactions to man and which responded similarly to hormones, if the results were to be extended to man He described a series of experiments by which he had shown that the guineapig was a suitable animal He went on to show that significant variation in allergic response was obtained with several hormones Anti- and pro-diabetic factors exerted an effect, and significant desensitisation of tissues had been obtained with a recently isolated and quick acting thyroid derivative Sensitivity to tuberculin could be related inversely to blood sugar levels, and partial pancreatectomy prevented the increased response seen after treatment with thyroxine, which therefore acted through the islets of Langerhans He concluded that immunity was probably due to the balance between insulin and cortisone at any one time

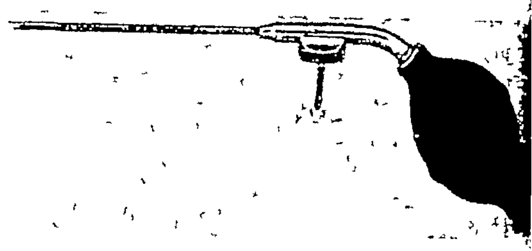
Dr G G **Meynell** discussed the protective function of the gastro intestinal tract against infection He had found that *Salmonella typhimurium* was killed at pH2 in two to three minutes He had also shown that if the gastro intestinal flora in mice were modified by the administration of streptomycin, their resistance to an oral dose of *S typhimurium* was decreased, and also that the organisms given by mouth could be recovered from the large gut This type of effect might be important in man

During the discussion, Dr **Brian Lacey** wondered whether sufficient attention had been paid to the genetic constitution, age, and sex of the mice used, and Dr A Felix, F R S, asked whether Professor Dubos's results were to be explained solely in terms of local cellular effects, or whether antibodies could account for some of them Professor **Dubos** felt that all the observed effects were probably mediated through a common channel, which facilitated both local tissue reactions and antibody res[illegible] On the question of applying the results of [illegible]ments to man, he said that no one knew better than he that mice and men were different, but justified the choice of a different animal when question to be answered by the experiment was sp and sufficiently limited

New Inventions

A MODIFIED THROAT SPRAY

In throat sprays used for spraying the throat befo endotracheal intubation or instrumentation, the b is joined to the nozzle by a flexible tube, with the re that the operator has to use both hands, and may n the services of an assistant The throat spray illustrat



here can be operated single-handed It is simple a sturdy in construction, inexpensive, and effective T nozzle is long enough to be introduced between th vocal cords for local preparation of the trachea. T Macintosh-type container keeps the volume of lo anæsthetic within safe limits and has the addition advantage of being unbreakable With a shorter nozz the spray should also prove valuable in otolaryngology

The instrument can be obtained from Medical & Indus Equipment Ltd, for whose coöperation I am grateful.

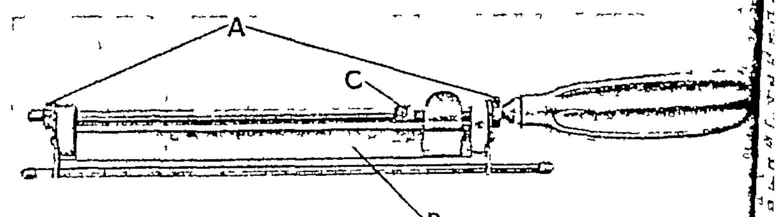
MODIFICATION OF HUMBY KNIFE

There have been several modifications of the orig Humby knife, with the aim of making it lighter enabling the blade to be readily replaced and adju In a new model, made at my suggestion by M Allen & Hanburys, these modifications have b combined, and in this model the instrument need not dismantled to replace the blade Ease of sterilisation storage have also been considered

This new modified Humby knife is light and w balanced Adjustment between the roller and the b from 0 01 mm to 1 0 mm is made by two kn collars (A) mounted on the back of the knife The bl



$6^1/_4$ in long, is of the wafer-razor type and is lock securely in a leaf-spring holder (B) To fit a new bl it is only necessary to move a safety catch (C), open th leaf and insert the blade under the roller, and repla the safety catch

The knife without the blade can be sterilised b boiling, without risk of damage, and the blade sterilis in the same manner as the standard interchangeab scalpel blades Since the blade can be fitted and remov quickly and easily, no protective cover is necessary f sterilisation or storage.

Reviews of Books

roanatomical Basis for Clinical Neurology

TALMAGE L. PEELE, M.D., associate professor of anatomy in charge of neuroanatomy, Duke University School of Medicine New York and London McGraw Hill 1955 Pp 664 100s

UCH has been said of the necessity for integrating siological and anatomical knowledge with sub- ent clinical training Most formal textbooks of tomy do, in fact, include paragraphs, usually in very ll print, devoted to applied anatomy Unhappily h excursions rarely succeed and it is often hard to ern the true links between form function, and deal disorder Dr Peele in this new textbook is very nitely aware of the trefoil nature of this teaching blem and equipped with a practical training in earch neuro-anatomy and clinical neurology, he has acked it *in admirable fashion*

fter a short but adequate and well illustrated account he histological and embryological details of the nervous tem, he gives formal sections on descriptive anatomy of its ious components. In each section however there also ears comment on the physiological factors relating to the ctures described together with some of the more important hological changes to be expected and their clinical mani ations. Thus the account of the blood supply and ven ular system of the brain is followed by a short discussion he circulation of the cerebrospinal fluid a description of its mical and physical properties, and the clinical aspects of reased intracranial pressure Similarly the factual account he spinal cord is accompanied by physiological and clinical ail which though brief will at once inform and stimulate preclinical student In discussing recently acquired tomical knowledge Dr Peele maintains his standards nature and activity of the reticular formation are clearly ribed and recent electrophysiological work on the ebellum is succinctly presented. Some of this more con versial evidence is perhaps offered a mite too firmly but teaching it is important to take up a reasonably definite itude. He is in any case to be congratulated on the healthy ticism he displays about the present evidence on the ppressor zones.

his admirable book is well illustrated and includes omprehensive bibliography

dern Trends in Ophthalmology

3rd series. Editor: ARNOLD SORSBY M.D., F.R.C.S London: Butterworth 1955 Pp 346 65s

rofessor Sorsby is again to be congratulated on his rnational team of contributors, who give an admirable vey of knowledge which has not yet reached the tbooks. The book is arranged in sections dealing in n with the basic sciences on which ophthalmology ts, advances in diagnostic procedures, clinical and perimental pathology clinical aspects in treatment, d social aspects. Adequate space has been given to the est developments in anatomy physiology and patho- y and Professor Sorsby himself has contributed good pters on the nature of malformations, and on strepto- cin and the new antibiotics, as well as on the social pect of blindness. With Miss Mary Savory he also tes on cortisone and corticotrophin in diseases of e eye

actions with Drug Therapy

HARRY L ALEXANDER M D emeritus professor of clinical medicine Washington University medical school Philadelphia and London W B Saunders. 1955 Pp 301 52s 6d

THE increased frequency of drug reactions in the past o decades has prompted Professor Alexander to compile s volume. He defines the reactions as lesions occurring only a small proportion of treated patients, differing om pharmacological effects and overdosage effects of e drugs and induced by therapeutic or subtherapeutic ounts

Only a few reaction patterns occur the main ones are matological manifestations, blood dyscrasias, serum sickness, shock, bronchial asthma, hepatitis, and polyarteritis nodosa. In the opening chapters of the book these patterns are described and their mechanism is discussed Controversial aspects of the subject are not fully discussed and this section is clearly not addressed to the specialist The general clinician may find the argument difficult to follow in places, and in many passages the syntax suggests overhasty revision. In the second part of the book many commonly used drugs and the reactions to which they give rise are described. Here the presentation is clear and informative and a coherent text replaces the catalogue common in works of this kind

Vitamins and Hormones

Advances in Research and Applications Vol XII Editors ROBERT S HARRIS professor of biochemistry of nutrition Massachusetts Institute of Technology Cambridge Mass; G F MARRIAN professor of medical chemistry University of Edinburgh; KENNETH V THIMANN professor of plant physiology Harvard University Cambridge Mass New York and London: Academic Press. 1954 Pp 303 $7.50

THE emphasis in this volume has been on vitamins, and consequently on nutrition; but three of the eight articles deal with hormones.

The first by John Hammond of Cambridge deals with the effects of light on hormone production and is concerned chiefly with seasonal changes, particularly those of reproduction which can be induced in warm blooded animals by modifying the illumination There is an interesting review by R B Bradbury and D E White (Western Australia) on oestrogens and related substances in plants, and one for practical men by F W Lorenz (California) on the effects of these oestrogenic hormones on the domestic fowl and their value in the poultry industry for fattening and other purposes. There are two papers on vitamin A—one by Saul H. Rubin and Elmer De Ritter from the Hoffmann La Roche laboratories, New Jersey dealing with the vitamin A requirements of animals, and the other by C Nieman and H J Klein Obbink of Amsterdam, dealing with the biochemistry and pathology of hypervitaminosis A. Both these papers are pertinent at the present time since the synthesis and large scale production of vitamin A has recently been effected by Hoffmann La Roche The authors give a valuable table summarising the dosages which have already proved toxic for man and the times for which they were administered Two English scientists, S K Kon and J W G Porter have contributed an account of that most complex but important subject the synthesis of vitamins in the ruminant: it now appears certain that the host and the micro-organisms in its rumen have established a nutritional symbiosis which is responsible for the provision of far more than the vitamins which the host requires. The article on the chemistry of vitamin B_{12} by Karl Folkers and Donald E. Wolf who are working in the Merck laboratories New Jersey is the most highly specialised and also the longest paper in the volume. The article by Charles S Davidson of Boston Massachusetts, on disturbances in nutrition relating to liver disease in man is a short and very readable account of current views on kwashiorkor alcoholic cirrhosis and other clinical disturbances in which the liver plays a prominent part

Doctors may be recommended to begin reading here; chemists, physiologists, and animal husbandmen will probably begin somewhere else in the volume but all may be recommended with confidence to begin.

A Handbook of Emergency Toxicology

A Guide for the Identification Diagnosis and Treatment of Poisoning SIDNEY KAYE B.S M SC associate professor of legal medicine Medical College of Virginia Springfield Ill Charles C Thomas Oxford: Blackwell Scientific Publications. 1954 Pp 303 42s

HE is a brave man who sets out to write an acceptable book on toxicology for the subject matter is about as inspiring as the contents of Bradshaw or a street directory Mr Kaye's great diligence shines out from the pages of his handbook but he has been no more successful than his predecessors in writing a best-seller

Upwards of 200 pages are occupied by a routine review of common poisons arranged alphabetically A telegraphic style is adopted this may be an advantage in a book designed for quick reference, but it inevitably makes this part of the text unreadable There is a table showing the names of the poisonous constituents of a large number of proprietary compounds —headache powders, weed killers, and the like Another table sets out the poisons contained in household articles—cosmetics, inks, matches, metal polish, and a score of the other perils that lie about us in our infancy It is difficult to imagine that anybody will get much help from the chapter on symptoms and signs to list 29 poisons and 15 diseases which may cause vomiting, purging, and abdominal pain does not suggest a very enlightened approach to toxicology, a few general principles would have been more valuable, especially if the subject could be correlated with physiology, pharmacology, and clinical medicine The author devotes only a paragraph to general considerations in this chapter, and the guidance here falls short A chapter on analysis provides a short survey of some of the chemical techniques of toxicology, but it is too meagre to interest the analytical chemist or the hospital biochemist In a book for students and practitioners, a competent essay on the collection of samples for expert analysis would be more valuable

Such books as this provide the best of all arguments for transferring the teaching of toxicology to departments of pharmacology, where the basic sciences are steadily ousting empiricism

Modern Trends in Psychosomatic Medicine

Editor DESMOND O'NEILL London Butterworth 1955 Pp 375 55*s*

PSYCHOSOMATIC medicine, though new in some of its aspects, is as old as medicine itself in others Some of the twenty articles in this fourteenth volume of the excellent *Modern Trends* series set out old and well-accepted views on the influence of the mind on the body, others offer less well-known and certainly less well-accepted ideas on a diversity of bodily, emotional, and psychiatric conditions The book contains most of the clinical evidence relating such disorders as thyrotoxicosis, ulcerative colitis, asthma, and skin diseases to psychological disturbances, and reviews the psychosomatic concept in medicine in general To the enthusiast it will offer a multitude of opinions confirming his belief that almost every illness is due to psychological stress In the sceptic it may provoke bewilderment and doubt that so much can be attributed with such confidence to such a cause, for though parts show a true and keenly scientific approach and parts are statistical, other chapters are mainly conjectural, and a few are almost frivolous The pleasantly classical and humanistic flavour of much of the writing is refreshing, and the references are copious and well chosen Dr O'Neill is to be congratulated on presenting such a full and varied picture of his subject, even if it may seem, perhaps inevitably, more one-sided than it should

Diagnostic Advances in Gastrointestinal Roentgenology

Selected Methods, with Clinical Evaluation ARTHUR J BENDICK, M D, director of radiology, Beth Israel Hospital, New York New York and London Grune & Stratton 1954 Pp 131 $6 00

IN the preface to this book the author states that "it is not intended for beginners but for radiologists of several years' experience, so situated that they cannot keep up with all the new techniques or the more modern interpretations of roentgen findings" Unfortunately it fails of this purpose, for it contains many inaccurate statements

Thus we are told that gravity does not play any appreciable part in the passage of barium from the œsophagus to the stomach, that the detection of neurological interference with swallowing is aided by demonstrating less distinct elevation of the hyoid bone on the films (but not how or under what circumstances), that the "club soda" technique in achalasia can be used as a method of deciding operability (but not how), and that amyl nitrate (not nitrite) is given to demonstrate the cardio œsophageal junction in achalasia We are told too "that the muscle of the diaphragm plays only a minor role in constricting the œsophagus at its lower end"

It [illegible] not, on the whole, to be able to recommend a b[illegible] ich a sound object

Antenatal and Postnatal Care (8th ed Lond J & A. Churchill 1955 Pp 672 37*s* 6*d*) —In p this edition of his reliable and senior textbook Prof F. Browne has had the collaboration of his son, Prof. J McClure Browne This family combination seems to worked well In including new work on the toxæmias pregnancy they draw attention to the work at the Wome Hospital, Sydney, Australia, where a determined campa to prevent eclampsia has resulted in a decline in incide from 1 in 400 in booked patients in 1946 and 1 to 1 in 20,000 patients since, in the 1 failure, a ri blood-pressure had been overlooked The Brownes find t in every eclampsia patient there are one or more warn signs which should lead at once to prophylactic treatment, their book does everything possible to ensure that th and other warning signs, in pregnancy and after, are missed

Alexander the Great and his Time (London Rock 1955 Pp 300 25*s*) —Dr Agnes Savill, well known as th editor of her husband's popular *System of Clinical Medic* has turned historian and here recounts the adventurous romantic story of Alexander the Great Alexander beca king of Macedon on the murder of his father, inheriting best equipped and trained army in the world At the age twenty he made himself master of Greece and began wonderful conquests marching from Macedon across th Hellespont to Egypt and from there through Persia to th upper reaches of the Indus in Hindu Kush When he d at the age of thirty three he had marched with his ar nearly twenty two thousand miles often under unbeliev difficult conditions He fought innumerable battles, us after a long forced march or a hurried climb up what enemy believed to be an unclimbable cliff or mount His weapons were surprise, swiftness of decision, imaginat foresight, ability to inspire and maintain the coöperat of his subordinates, and superb physical fitness and athl skill Dr Savill has written an interesting book. On left wondering whether she does not rebut too freely of the calumnies heaped on Alexander by some histori But if she tends to gild her lily, she leaves no doubt the reader's mind of the qualities that made Alexa great

Principles of Internal Medicine (2nd ed Lond H. K Lewis 1954 Pp 1790 £5 10*s*) —When the edition of this book by Dr T R Harrison and his coll was published in 1950, it was at once accepted as an auth tive textbook of American opinion The second e establishes it even more firmly as a standard work of ref The general arrangement is the same as before The third deals with general considerations and the rem considers the different systems of the body one by A new chapter on the general care of the patient gi useful review of nursing principles and the treatment symptoms in general The new edition is some 200 p longer than its predecessor, and with somewhat c print and some compression of space it contains a great more—Chapter headings have gone and some of the illus tions have been much reduced in size The index has, great gain, been almost doubled in size The contribu now number 85, an advance of about 30 An important section of over 100 pages, which replaces the section weakness, is written by Dr R D Adams and his asso and includes an excellent and lucid account of the an states, depression, sleep disorders, fits, delirium, co and the psychoses

I was a Drug Addict (London Rider 1954 Pp 15*s*) —Although Mr Leroy Street assures us that his acc is "uncoloured" the literary form evidently owes much to collaborator, Mr David Loth, who is a professional wr Fewer sentences such as "these homely objects were abo convey a new meaning to my specially alerted brain," fewer verbatim conversations would make the auto graphical statement seem more authentic As it sta however, it describes, in rather exaggerated language subjective experiences and the companionship which drug addict meets in his descent There is no obvi improbability in all this, except for the happy ending wh represents permanent recovery as the outcome of a fortu self directed plan for reducing the dose of morphine grad The work has social rather than medical or psycholo interest

THE LANCET

LONDON SATURDAY MAY 14 1955

Orbital Leucotomy

Standard leucotomy, or lobotomy developed y **Freeman** and **Watts** in which a large part of the refrontal areas is severed from the rest of the brain, as of late been carried out only in cases of long anding mental illness with severe behaviour dis rder Apart from the unpredictability of its atomical results it commonly causes undesirable rsonality changes These changes, it was observed, ere more likely to occur when the operation had een extensive and attempts were therefore made to mit it to a minimum Clinical observation of atients with frontal lobe injuries, as well as experi ental work, suggested that a regional factor was portant Several workers reported satisfactory sults from "lower quadrant" operations aimed at olating only the orbital part of the frontal lobes hese, like the standard leucotomy, were still blind rocedures lacking in precision With the increasing e of open operations various selective methods have een developed. One of the most interesting of these the undercutting of certain parts of the frontal rtex first proposed by **Scoville**[1] who compared e effects of undercutting three cortical areas with ose of standard leucotomy The areas chosen were e superior surface of the frontal pole the orbital urface, and the medial surface of the cingulate gyrus e found that in schizophrenia and the affective tates undercutting the superior or the orbital surface rought about the same results as the standard peration, but with less personality defect. He garded undercutting of the orbital surface "as e ideal operation for psychoneuroses and the milder ood disturbances because of the almost complete bsence of personality changes There was much o recommend the choice of that particular area for atients with otherwise intractable anxiety and epression

The importance of this area as part of the cerebral ubstrate of emotional integration is now generally ecognised **Tow** and **Lewin**[2] described the results f undercutting the orbital surface in twenty patients ith various mental disorders who were subsequently followed up for two years. The effects were comparable with those of the standard operation, but the personality changes were less pronounced. Two reports on earlier pages of this issue appear to confirm the value of the method Dr **Ström Olsen** and Mr **Northfield** have applied it to a group of patients with chronic neurotic tension states, in each of these patients, including one with pronounced paranoid ideas, depression was prominent More than half recovered from their symptoms and personality changes were slight Another group, suffering from long standing schizophrenia with personality deterioration, did less well Mr **Knight** and Dr **Tredgold** report on a series of fifty two patients subjected to a slight modification of cortical under cutting Their results are almost as impressive as those of **Ström Olsen** and **Northfield** They also found that improvement was most striking in patients with anxiety and depression Patients with hysterical symptoms did not respond favourably The two reports confirm the beneficial effect of orbital under cutting and the absence of severe postoperative personality changes, but it is difficult to compare the results in detail since these were differently assessed. **Knight** and **Tredgold** eschew the term "recovered" used by the other group of workers, but it can be assumed that the majority, if not all, of their "much improved" patients would have been classed among the "recovered" by **Ström Olsen** and **Northfield** Evaluation and classification of therapeutic results is a serious problem in psychiatry, and communication between workers in the same field is often bedevilled by the pitfalls of semantics

The fact that an operation as limited as orbital undercutting can produce a substantial and often dramatic change in the mental state seems at first to contradict the view held by earlier workers that the degree of improvement depends chiefly on the amount of brain substance isolated **Meyer** and **Beck**[3] suggest that, though the extent of the operation is important regional localisation of the cut within the frontal lobe also influences the effects They point out that some very limited regional cuts may in fact, by severing the thalamofrontal projection, isolate large areas of cortex The question, therefore whether the frontal lobe functions by mosaic or mass action has still not been finally answered In their experience, the extent of the cut, wherever localised is correlated with improvement But various types of improvement follow surgical interference with frontal lobe function one is the complete disappearance of symptoms, especially of depression, immediately after the operation almost any operation on the frontal lobe however limited has sometimes resulted in this dramatic change In such instances at any rate, improvement or even recovery does not seem to have been bought at the price of a severe personality change, so obvious in other patients The results of cortical undercutting show that notoriously reversible symptoms, such as depression and anxiety, can be removed sometimes by a very limited operation—an effect which, though profound, is clearly unrelated to the personality change

---

[2] Tow P M, Lewin, W *Lancet* 1953 ii 644

[3] Meyer A, Beck E Prefrontal Leucotomy and Related Operation Edinburgh, 1954

In what type of patient can one expect such a distinct improvement? Here we are still in the dark Ström-Olsen and Northfield consider that neuropathology may some day provide the answer Some workers believe that it will eventually be possible to produce lesions to suit every condition and every patient The fact that the results of a precise and limited operation, such as orbital undercutting, are still inconstant, suggests that the effect does not depend only on the extent and localisation of the lesion The patients' personality—the sum total of his response patterns, innate and acquired—must be of considerable importance Only when we know more about the reactions of the personality to sudden alterations in the emotional charges shall we be able to predict the effects of surgical treatment in individual cases The psychiatrists, it is true, have been aware of this, and have generally accepted that in well-integrated personalities the likelihood of undesirable postoperative behaviour features, even after extensive operations, is small, but beyond this we know very little Naturally, clinicians are more interested in their successes, especially when a method has still to be established But the time comes when careful and systematic study of failures and partial failures is at least as important as that of successes This is particularly true in the present stage of the surgical treatment of mental disorders Such studies would also act as a wholesome corrective to the danger of a reversal to "atomistic" concepts of cerebral function The effects of localised operations on mental states have contributed to a revival of concepts reminiscent of those so persistently criticised by Hughlings Jackson, and a language has crept back into medical writings which not so long ago seemed almost extinct What would Jackson have thought of the "intellectual pathways" referred to by Knight and Tredgold? The passage from Le Gros Clark cited by these workers, and Meyer and Beck's[3] recent warning against too atomistic an interpretation of the effects of brain operations, show that at least some of those most familiar with cerebral structure and functions are opposed to a return to the old-fashioned rigid localisation of functions Only by taking into consideration the undamaged parts of the brain and the reactions of the whole personality shall we reach a fuller understanding of the scope and limitations of the surgical treatment of mental disorders

Estimation of Blood-loss

The most important cause of shock after surgical or accidental injury is loss of blood into and from the damaged tissues, or of plasma in cases of burns and scalds, or of crushing Such shock usually responds to the rapid replacement of the lost fluid, but measurement of the amount lost, even at operation, is not easy

Estimates based on impressions during the operation are usually too low, even when reinforced by collection of the swabs, towels, and gowns Surgeons who have not submitted themselves to the discipline of direct measurement of blood-loss usually find it hard to believe the figures obtained in this way Som [illegible] for example, when the operation is for e [illegible] arance of viscera in the pelvis or of a large block of organs in the upper abdomen—estimates based on impressions are of hardly any value, and when, in addition, the operation lasts many hours and is accompanied by transfusion to replace lost blood, direct measurement is especially necessary To be useful the method of direct measurement must provide an accurate answer shortly after the operation has ended Probably the simplest way is to wash out all the swabs, towels, gowns, and instruments in a known volume of water, to which is added the contents of the suction bottle The hæmoglobin level of this fluid is then measured either directly[1] or after conversion to acid hæmatin[2 3] This, together with the hæmoglobin level of the patient's blood before and immediately after operation, gives a fairly accurate guide to the volume of blood lost. Paquin et al[4] have devised a method suitable for cases in which blood or other intravenous fluids are being administered The difference between preoperative and postoperative weight is corrected on the one hand for additions (including dressings and transfused blood or other fluids), and on the other hand for depletion by bleedings, estimated insensible water-loss, resected tissue, and excreted urine and other lost body-fluids As a check they also measure blood-loss directly,[5] by weighing the towels, swabs gowns, and suction-fluid They have found close agreement between the results by these two methods, even for operations lasting ten hours with a blood loss of over 4 litres But they point out that serious errors may arise from the accumulation of shed blood in "dead spaces"—for example, the pelvis—and from excretion of urine or, in operations on the urinary tract, from contamination of blood with urine Furthermore the method of Paquin et al cannot be expected to give really reliable results until we know more about the possibly wide variation in insensible water-loss during different types of anæsthesia and they themselves emphasise that their method should be combined with clinical examination before deciding on treatment Fortunately operations lasting for more than three hours are rare, and the amount of blood lost at operation seldom exceeds 2 litres

Measurement of blood or plasma lost by accidental injury is even less easy Theoretically such loss would be best measured by estimating the amount of blood remaining in the circulation and subtracting this from the normal volume, which, as Gibson and Evans[6] showed, is closely related to body weight But this approach is so studded with pitfalls that others have been tried Noble and Gregersen[7] found that in civilian injuries blood loss depended largely on the extent of muscle damage and the number of fractures, and Grant and Reeve[8] showed that in limb injuries the volume of damaged tissue was a good guide to the volume of blood lost Mr Ruscoe Clarke and his colleagues[9] have

easured the increase in the volume of injured limbs d also the red blood cell volume, and have tablished that estimates of blood loss based on ese two measurements agree closely Their findings nfirm the close relation of blood loss to muscle jury, which is particularly severe in fractures volving the shaft of the femur or the pelvis. Never eless, although the bleeding associated with such juries is commonly underestimated, there is still sufficient evidence to justify the very large trans sions of blood recommended by PRENTICE et al[10] arly surgical treatment should be combined with pid transfusion of enough blood to maintain the ood pressure within normal limits The anæmia hich follows severe injury presumably reflects e general post traumatic protein katabolism, and ould not be treated prophylactically by the dministration of blood in excess of that needed to store circulatory efficiency

The Mystery of Dental Caries

DECAYED teeth have caused the human race suffering nd unhappiness for several thousand years In ncient times dental caries was associated with the dea of worms in or around the teeth, and this notion ersists in the primitive cultures of today It seems hat a certain JAQUES HOULLIER (1498–1562) first ast doubt on the existence of dental worms, but that lid not prevent GOTTFRIED SCHULZ, who lived at bout the same period from declaring that the pplication of gastric juice from a pig would expel worms—some even as large as an earthworm—from a decayed tooth[11] GALEN believed that dental caries was produced by an abnormal condition of the blood which affected the internal structure of the tooth and recent work gives some support to this hypothesis The suggestion that micro-organisms might be responsible for caries was first put forward by LEBER and ROTTENSTEIN in 1867[12] A few years later, MILLER,[13] working in KOCH's laboratory in Berlin found that micro-organisms obtained from carious dentine produced lactic acid when cultured in the presence of sugar or starch, and he formulated the chemicoparasitic theory of dental caries In 1925 BUNTING and PALMERLEE identified the commonest acid producing organism in the mouth as *Lactobacillus acidophilus*

The chemicoparasitic theory together with the belief that dental caries is associated with the consumption of small molecule carbohydrates that are readily fermented, has been widely accepted for some fifty years. There is now much evidence supporting the theory, including the increased incidence of caries among Eskimos when refined carbohydrate foods were added to their normal diet[14] Investigations during and after the wars of 1914–18 and 1939–45 also seemed to suggest that when sugar was rationed and other highly refined carbohydrates were scarce the incidence of dental decay in children dropped sharply whereas it rose again sharply in the post-war years. More recently many research workers have come to believe that the incidence of caries is influenced by other factors—the structure of the tooth, conditions affecting the metabolism of the body and the ingestion of fluorides in drinking water Some workers now believe that caries is initiated by proteolysis of the organic constituents of the enamel and that decalcification is secondary

A report just issued by the Medical Research Council[15] throws considerable doubt on the idea that caries in children is caused at least partly by excess of sugar in the diet This report describes trials in London, Liverpool, and Sheffield on the effects of adding extra sugar to the diet of children in residential homes The incidence and spread of dental decay in groups of children aged 2–14 years, was first observed for a year, during which the children received their normal diet containing liberal amounts of milk fresh fruit, and vegetables, and, in most cases supplements of cod liver oil and orange juice The children were then divided into two groups one continued to receive the normal diet while the other received additional white sugar The dental condition of this group was compared with that of the controls at the end of 1 $1^1/_2$, and 2 years Since work by OSBORN et al[16] had suggested that unrefined sugar might contain some factor which tended to protect the teeth from attack by caries, raw sugar was included in the diets of some of the test children. The diets were arranged so that the control groups received 11 oz of sugar a week, while the test groups received just over 22 oz of white sugar or about $21^1/_2$ oz of raw sugar The results were somewhat unexpected Despite the relatively large differences between the amounts of sugar given to the control and to the test groups there was no significant difference in the incidence or the spread of dental caries during the 2 years There were some anomalous findings—for instance, some of the children who received extra white sugar actually had a significantly smaller incidence of caries than the controls—but these findings showed no consistency when the results were surveyed as a whole There was no evidence that sugar affects the two dentitions differently As far as could be ascertained, unrefined sugar does not contain a caries inhibiting factor

None of the children in the trial groups received more than about 4 oz of sweets a week and the report does not prove or even suggest that unlimited sweets are harmless Mr E B DOWSETT, in his presidential address to the British Dental Association in 1951, suggested that sweet-eating by children should be controlled[17] In his view sweets made from glucose—as many now are—are more dangerous to the teeth than those made from sucrose The problem of caries is undoubtedly in the broadest sense dietetic But what aspect of the diet is at fault? Is there a local and external effect on the tooth, or is it systemic and internal? These possibilities are not mutually exclusive and if the latest report has done no more than eliminate another hypothesis that at least brings us one stage nearer the solution

REGULATION OF CARDIAC PERFORMANCE

Starling's classical work on the isolated dog heart demonstrated that the strength of its contraction, and therefore stroke output, was determined by diastolic ventricular volume This accorded with expectation, since the strength of contraction of striated muscle is, within physiological limits, determined by the initial length of its fibres In recent years Starling's law has been much discussed in relation to adaptation of the heart to disease, and an exceptionally well documented symposium on this important topic has now been published [1–9]

Three different sets of observations must be considered (1) on the isolated heart preparation where reflex, nervous, and hormonal influences are excluded, (2) on healthy intact mammals, and (3) on patients with heart disease

In the isolated heart the validity of the Starling principle is accepted,[5] but its exact mechanism is still disputed [6] "Venous return" is often said to determine cardiac output, but in any balanced state of the circulation venous return must be the same as the cardiac output Increased diastolic filling of the heart is much more likely to result from increased venous pressure, and this can occur physiologically by contraction of the spongework of venules and other small peripheral vessels pushing more blood towards the centre Guyton [3] has elaborated the conception of "mean circulatory filling pressure," which is the external squeeze of vessels on their blood content with flow factors eliminated This can be measured experimentally during induced temporary ventricular fibrillation, after which rhythmic cardiac contractions are re started by electric shocks As might be imagined, this "static" filling pressure rises with increasing volumes of blood in the circulation Though most of Starling's data showed a correlation between venous filling pressure and cardiac output, Starling himself appreciated that the filling of the heart might sometimes be greatly increased by very small pressure changes Katz,[10] using Wiggers's methods of accurate optical recording, showed that changes in cardiac output paralleled end-diastolic ventricular pressure It is, of course, better to estimate cardiac performance as *work* rather than simply as *output* Sarnoff,[2] who has re-studied the whole matter, has shown a linear correlation between venous filling pressure and *right* ventricular work, and when the left ventricle was loaded by increasing aortic resistance, pressure rose in parallel in the *left* atrium but not in the right Homolateral correlation is thus of the greatest importance For any given filling pressure the work of individual hearts could be increased by adrenaline or decreased by experimental restriction of coronary flow [2]

In intact animals and man the situation is more complex, since the heart is innervated and is exposed to varying amounts of endogenous adrenaline and other influences which may counteract the influence of changes in venous filling pressure End-diastolic volume and pressure may not always correspond if muscle tone can alter [1] While McMichael and Sharpey-Schafer [11] showed a significant general correlation between cardiac output and venous filling pressure in man, Warren et al [12] emphasised the exceptions to this rule Gregg et al [4] have found in the whole dog a general correlation between cardiac output and filling pressure when raised by intravenous infusion, but the correlation was not clear at lower rates of infusion Gauer [7] demonstrated close correlation between diminishing heart volume and stroke output in monkeys subjected to centrifugation Hamilton [9] reminds us that in many experiments with isolated animal hearts the outputs are artificially set much lower than the expected normal for the particular animal Starling's law might be particularly easy to demonstrate under these conditions Richards [8] calls attention to the Swedish radiographic studies of heart volume, which show clearly that in exercise the heart increases in size only very slightly The increased output of effort is certainly brought about by increased rate and increased emptying of the ventricles—increased emptying has been of special interest since it was realised that under resting conditions the ventricles almost certainly do not empty completely and contain some residual blood at the end of systole

In patients with heart failure due to intrinsic heart disease the output tends to be relatively fixed, dropping to subnormal levels in the more advanced stages Heart rate in failure also tends to settle round 100 a minute Such hearts seem, like the kidney in advanced nephritis, to have lost their flexibility of response With this loss of fine adjustment, Starling's law may be the last resource of adaptation to pathological conditions In failing hearts the common absence of increase in cardiac output during exercise, despite a rising venous filling pressure, and other observations led McMichael and Sharpey Schafer [13] to the hypothesis that the failing heart behaves as though it were no longer responding normally to increases in venous pressure, such increases could even be accompanied by a falling cardiac output, and, conversely, lowering of venous pressure by venesection could be followed by improvement in cardiac output These observations may have to be considered in a new light, for Sarnoff [2] has pointed out that decreasing stroke work at high filling pressure is attributable to regurgitation through the atrioventricular valves The studies of Korner and Shillingford [14] show that some tricuspid incompetence is often present in heart failure The extent of this incompetence and its part in producing the congestive features of heart failure have not yet been fully appreciated

POLIOMYELITIS REVIEWED

WITHOUT doubt the great advances in our knowledge of poliomyelitis in the last few years began with the discovery by Enders, Weller, and Robbins [15] in 1949 that poliomyelitis viruses could readily be grown in tissue-cultures—a discovery which won them the Nobel prize in physiology and medicine for 1954 Thereafter our knowledge of epidemiology, pathogenesis, and prevention expanded at a great rate, and the new ground explored has lately been reviewed in a World Health Organisation monograph [16] In this Enders himself gives a beautifully clear exposition of tissue-culture techniques as applied to poliomyelitis, and Rhodes, Wood, and Duncan illustrate the application of these techniques in laboratory diagnosis Gard writes about the virus itself—*Poliovirus hominis* and the related *P muris* to use the correct terminology The new tissue-culture techniques have been applied first to urgent practical problems, and most of our theoretical knowledge of the virus is still based on earlier studies of infected nervous tissue, in which the virus may represent only one

millionth to ten millionths of 1% of the tissue It is therefore important to re-examine the properties of the virus grown in the more satisfactory milieu of tissue culture now available; to take only *one point it is* vital for vaccine production to know the resistance of the virus to different forms of inactivation Methods of inactivating virus on the skin are scarcely of less interest, since there is still a possibility that virus on the skin may be implanted by injections and on this matter Bard says "It can only be stated that, as a means of removing or inactivating virus on the skin the use of soap detergents, ether ether alcohol, or chloramine is nothing but a symbolic ritual only iodine might be expected to serve the purpose

Hammon describes the first stage in the striking progress in protection—passive immunisation with gamma-globulin The first large-scale trials in 1951 and 1952 showed that gamma globulin gave some temporary protection against paralytic poliomyelitis, and later work has demonstrated that the all important subclinical infections were not prevented. But mass administration of gamma globulin during epidemics has been disappointing and its use *for prophylaxis of contacts* cannot now be recommended for the first detected case in a family is seldom the first to be infected Hammon suggests that gamma globulin may be most useful in dealing with outbreaks of poliomyelitis in summer camps and boarding-schools. It is clear however that active immunisation is the main hope in preventing poliomyelitis, and in the monograph this subject falls to Sabin and Koprowski Sabin discusses immunity as a result of natural infection of man or experimental infection of animals with special reference to vaccination, and he is much concerned with variations in virus virulence Tissue-culture methods allow the detection of naturally occurring viruses of low virulence, and Sabin's important laboratory experiments have segregated avirulent virus variants which might later be used to immunise man. As we pointed out in a leading article last month[17] both Sabin and Koprowski believe that live avirulent poliomyelitis virus will prove best in the end; and this view may well find wider support when the difficulties that are now besetting the immunisation programme in the United States have been fully investigated Sabin and Koprowski have made considerable advances both in *preparing* avirulent variants *from all three* antigenic varieties of virus and in testing some of them in man There are many difficulties ahead in this field, but there is no reason to believe that they cannot be overcome in the next few years On p 1018 we report some of Sabin's latest findings which he described to a meeting of the Association of American Physicians last week

Our outlook on the epidemiology of poliomyelitis has also undergone some sharp changes of late, and these are discussed in the monograph by Paul Gear and Froeche and *Nielsen* Poliomyelitis is world wide and in nearly all countries paralytic cases have become commoner and the disease has attacked older people The virus has spread widely however *in underdeveloped countries* where the disease has the characteristics of infantile paralysis —that is paralytic cases are less common in adults and are largely confined to infants widespread subclinical infections in infancy protecting against paralytic disease in adult life Similarly the first recorded epidemics in Scandinavia North America Australia and New Zealand fifty to seventy years ago were all infantile paralysis. The sparing of adults suggests that they were protected by previous subclinical infection and it need not be assumed that this was a new disease The changed characteristics of poliomyelitis have in fact been created by our changed hygienic habits Poliomyelitis is today under pressure to spread from underdeveloped areas into a *susceptible* population and if the inter-epidemic period is *long* the risk *of a severe epidemic increases* annually One of the most graphic examples of this is the Hudson Bay epidemic in 1948–49 when 60% of the Eskimoes had paralytic disease, all age-groups were involved the lowest clinical attack rate being in the infants Gear mentions another fact which brings home the changing pattern of poliomyelitis in Nyasaland and Southern Rhodesia paralytic poliomyelitis is today one of the most serious hazards facing newly arrived adult European settlers. Discussing public health measures, Payne points to the anomaly that so far as poliomyelitis is concerned hygienic measures may have done more harm than good He suggests that early in an outbreak, or with inter-epidemic cases, the application of hygienic measures may prevent an epidemic from starting once it has started the large number of sublinical infections makes further steps of this kind valueless

PANCREATITIS

MODERN treatment has greatly changed the clinical course of acute pancreatitis as Kirby et al.[1] have shown by comparing cases admitted to the Hospital of the *University of Pennsylvania* before 1946 with those admitted in subsequent years Of 80 patients in the twenty five years up to 1946 23 (29%) died the majority from vascular collapse shortly after the illness began in 1946–53 110 patients were treated with 21 deaths (19%) Deaths in this second group took place later only 3 (14%) of the 21 deaths took place in the first week of the illness compared with 20 (90%) of the 23 in the earlier group The manner of death has also apparently changed Secondary hæmorrhage which was not observed before 1946 accounted for 11 deaths in the second group, and in this group of those patients with hæmorrhagic pancreatitis who survived about a quarter bled either *from an abdominal* wound or into the alimentary tract Possibly antibiotic therapy has reduced the early toxic effects due to infection, so patients survive long enough for the erosive pancreatic enzymes to damage vessel walls and thus precipitate secondary hæmorrhage; Kirby et al. suggest that this complication may be prevented by proper drainage to encourage the escape of the enzymes.

The most severe form of acute pancreatitis was found after operations involving the pancreas There were 14 such cases with 8 deaths 7 from hæmorrhage In 6 of these 14 cases the pancreatitis followed subtotal gastrectomy in 5 subtotal pancreatectomy in 2 simple biopsy associated with cholecystectomy *and in 1 colectomy for a* growth adherent to the pancreas Obstruction of the pancreatic ducts is known to be a potent factor in precipitating pancreatitis[2] which for this reason is sometimes found in conjunction with carcinoma It is therefore not difficult to understand why pancreatitis follows operations such as gastrectomy or pancreatectomy, that may cause trauma to the pancreatic ducts But this does not explain all cases Millbourn[3] has drawn attention to the possibility of interference with the *blood supply to the pancreas by damage* to the superior and inferior pancreatico duodenal arteries *but* Warren[4] points out that the blood-supply is so generous that ligation of one artery alone would be unlikely to cause trouble Pancreatitis has *arisen as a late* complication of partial gastrectomy, through stagnation in the afferent loop and suggested causes include spasm of the sphincter of Oddi and 'sludging' of pancreatic secretions within the ducts as a result of *medication* and dehydration[5]

Injury to the ducts is the most important cause of *postoperative pancreatitis not only because* it is probably the commonest but also because it should be treatable—if not avoidable In Warren's[4] 7 cases of pancreatitis following partial or total gastric resection, 6 of the patients died with pancreatic necrosis In 4 of these a penetrating duodenal ulcer was reported, in any of these 4 cases a duct may have been damaged, while in a 5th carcinoma of the stomach may have involved the pancreas The pancreatic duct, the accessory pancreatic duct, or both, were damaged at operation for duodenal ulcer on 6 other patients, 3 were spared pancreatic obstruction by the development of a fistula, which healed subsequently or was successfully implanted into the intestine, and in 3 the ducts were reimplanted at the outset, all survived and pancreatitis did not ensue It is not easy to observe either of these ducts lying in inflammatory tissue near the base of a duodenal ulcer, owing to their smallness it is still less easy to reimplant them when they are seen, unless they have been dilated by long continued obstruction In this form of obstruction there may be a place for Duval's[6] ingenious technique for curing chronic relapsing pancreatitis[7] This condition is commonly thought to be due to obstruction at the sphincter of Oddi inducing biliary reflux into pancreas, but Duval doubts this and, believing that pancreatitis is caused solely by the obstruction and that biliary reflux is immaterial, he suggests that the pancreas be drained through its tail by transecting and implanting this into the open end of a Roux-en-Y jejunal loop He has successfully treated 2 patients in this way

DIAPHRAGMATIC RUPTURE

THE diagnosis of traumatic hernia due to non penetrating injury is easily overlooked Most commonly the patient has received a crushing injury to the abdomen, so attention is directed more to possible visceral damage than to the abdominal parietes and chest Of the 7 cases seen by Evans and Simpson[8] 4 had fractures of the pelvis In the case reported by Dr Hamdi and Dr Sturdy elsewhere in this issue the patient appeared to have only a head injury, but while anæsthesia was being induced for reduction of a depressed fracture herniation took place through a diaphragm weakened by injury They agree with Evans and Simpson that a sudden explosive rise in intra-abdominal pressure, due to straining under the anæsthetic, can precipitate herniation This two stage mechanism—diaphragmatic trauma followed by herniation due to a momentary rise of pressure from below—can lead to further diagnostic difficulty since the two events may be separated by a considerable interval In 2 patients seen by Evans and Simpson six months and two years elapsed after the injury before the onset of symptoms, which in 1 case started quite suddenly while the patient was lifting heavy weights After such an interval the original injury may have been forgotten, and there may be no tell-tale scars to recall it Coincidental rupture of abdominal viscera is uncommon, and acute symptoms usually arise from displacement of lungs on the one hand and strangulation of abdominal viscera on the other In the case reported by Mr Sinha, also in this issue, the spleen was ruptured, but bleeding from it began only at emergency thoracotomy for reduction of the hernia Often, too, there is no pain referred to the shoulder, perhaps because the phrenic peritoneum is insufficiently irritated by a simple tear

Accordingly the diagnosis may be extremely difficult In a case lately investigated by a coroner[9] a young woman had received injuries to her face, body, and hip in a car crash After six days in hospital she was discharged, but returned almost immediately with internal hæmorrhage At laparotomy this was found to be due to recent ruptur of the splenic vessels, the spleen itself was intact, lyin within the abdomen, while stomach and colon had passd into the chest through a hernia in the diaphragm Radiography had revealed a diaphragmatic hernia which w regarded as congenital, and from the necropsy appearances it was concluded that the hernia was of long standing and probably congenital This may be another example of the double mechanism of a faulty diaphragm resulting later in expulsion of viscera into the chest

UNIVERSITY AND TOWN

FOR three days last month the University of Sheffie opened its doors to the people of the town Almost ever department in every faculty had prepared demonstratio illustrating the work they were doing In the faculty medicine, the department of medicine demonstrat the incidence of the killing diseases in a remarka cheerful way, and they allowed visitors to estimate t capacity of their lungs with a spirometer The departme of therapeutics and pharmacology showed some isoto techniques for measuring blood volume, and every could have an electrocardiogram while they waite Blood-transfusion work was vividly illustrated by th department of pathology, and the department of surgery had demonstrations dealing effectively with septic han arterial disease, and gastric acidity In the departm of obstetrics and gynæcology, the cycle of life, throu fertilisation, conception, and birth, was portrayed b models and diagrams

MEDICAL ASPECTS OF NUCLEAR RADIATON

THE membership of the committee on the medic aspects of nuclear radiation which, as the Prime Minist announced on March 29,[1] the Government invited t Medical Research Council to form, has now be announced The chairman is Sir Harold Himswort F R C P, F R S, secretary of the council, and the oth members are

Sir Ernest Rock Carling, F.R C S, F.R C P, consult adviser, Ministries of Health and Home Office (Civil Defen and member of the health policy committee of the Ato Energy Authority, Sir John Cockcroft, F.R S, director, Ato Energy Research Establishment, Prof Alexander Hadd M D, director, Chester Beatty Research Institute, J F Loutit, D M, director, M R C Radiobiological Research Un Kenneth Mather, D SC, F.R S, professor of genetics, Bi ingham University, W V Mayneord, D SC, professor physics applied to medicine, London University, P Medawar, D SC, F.R.S professor of zoology and comparativ anatomy, University College, London, J S Mitchell, M. F.R S, professor of radiotherapeutics, Cambridge University L S Penrose, M.D, F.R S, Galton professor of eugen University College, London, Sir Edward Salisbury, F. F R S, director, Royal Botanic Gardens, F G Spear, M. deputy director, Strangeways Research Laboratory, Ca bridge, J R Squire, F.R C.P, professor of experiment pathology, Birmingham University, C H Waddingto SC D, F.R S, professor of animal genetics, Edinburgh U versity, Sir Lionel Whitby, F R.C.P, regius professor physic, Cambridge University, and B W Windeyer, F.R.C professor of radiology (therapeutic), London University

LEADERSHIP IN CARDIOLOGY *

The Charles Laubry Lecture

Sir JOHN PARKINSON

M.D Lond LL.D Glasg D.Sc N U I F.R C P
Hon. F.R C.P E Hon F.A C.P

 this lecture I am allowed to voice what is in my d and memory In my mind is the realisation that progress of cardiology has been mainly due to a ession of individuals who proved to be leaders in ught in action and notably in discovery In my nory is the state of medicine, including cardiology n I began as a young student fifty years ago and the nsformation that has since taken place I propose to ak on three separate subjects first of those early s and of that great leader James Mackenzie secondly specialism and the training of the cardiologist and rdly on French cardiology and the leadership of fessor Laubry

Days Gone By

May I look back at medicine as I found it in my own le at the London Hospital ? The study of the basic ences was limited to two years of inorganic chemistry sics, and biology Then followed two years of atomy happily under Arthur Keith while physi gy was too largely a system of conflicting hypotheses, ugh not for my own teacher Leonard Hill. All this ng over it was then our lot to live for as many hours possible with the sick in the wards and outpatient sics, learning by precept and practice what was ong with them and what to do for them We learned ly what our teachers knew except for what was in r textbooks, the most popular of which was Osler's o had no research consciousness though we were forced be clinically conscious In medicine our dozen teachers re equally chiefs ; but, looking back, how unalike their attitudes and talents ! Outstanding was Henry ad, an inspiring teacher but admittedly odd in having earch on the brain and even submitting to experi ntal operations on his own nerves Otherwise research d no place in the wards it was none of our business e were busy learning from our elders and there was a de variety of approach a wealth of practical experience those who moulded us One teacher one professor is ter enough the more the better—and often the rrier Among them was that fountain of clinical sdom, Sir Robert Hutchison who is still with us and o prayed From inability to let well alone from much zeal for the new and contempt for what is old ; m putting knowledge before wisdom science before art, verness before common sense from treating patients cases ; and from making the cure of the disease re grievous than the endurance of the same : Good rd, deliver us '

During my medical apprenticeship our clinical practice s mostly empirical and we were not bothered by hniques As a clinical clerk I did use the first sphyg manometer in the hospital and a thin X ray film uld drift into the ward though it might show little yond the fingermarks of the radiographer There was n no separate science of psychology but patients were ted and treated as kindly as today though with less derstanding for the state of mind of the sick was not lized. Sex did not exist as a subject to be taken into ount by all doctors I had read Oliver Wendell Holmes however and he said ' The sound of a kiss is not so loud as that of a cannon but its echo lasts a great deal longer ' There were two kinds of heart disease, valvular and non valvular and we were satisfied Digitalis was given for heart failure in the wards but forbidden to outpatients Antibiotics were scarcely on the horizon and infections ran their course Many physicians had lost faith in therapeutics and patients were pacified with traditional remedies culled from the hospital pharmacopœia

In those last fifty years, medical practice has become more rational while advance by experiment has largely replaced advance by observation yet there is still ample scope in clinical science for patient observation I have been impressed by the way that the science of mind, psychology has gradually permeated practical medicine. Doctors more often and more exactly try to realise in their own minds the position and feelings of their patients. This studied humanism has largely taken the place of what was called the art of medicine Indeed today we may speak more simply and truly of the science of medicine It has been said that he is the best physician who inspires hope, but too often he brought ' no other medicine but only hope no material benefit Comparing the past with the present it is surely in *treatment* that advances of the greatest magnitude have been made The medical profession is greatly strengthened by the good will and moral support of the community and nothing has elevated medicine in public esteem more than the spectacular progress in medical and surgical treatment in recent years.

Men and Heroes

How then has medicine and with it cardiology, grown ? It is surely a story of men It is biography It is the life and achievement of a succession of men and women—a few of them geniuses many talented and a host with fewer gifts but determined to use them well Thus in a volume like Herrick s *Short History of Cardiology* we read a story of persons and their ideas and achievements rather than a summary of theoretical and factual progress.

In our boyhood and youth we all had our heroes bright and shining maybe historical or fictitious or martial but scarcely political and not at that time medical. As we emerged from boyhood and came to the study of Medicine this hero worship was still strong in us persisting through our medical training ; and many of our teachers became and remain our heroes You will agree that this faculty of admiration hero worship can and often does persist and that it still exerts a power in our lives It has truly been said that we are a part of all that we have met

People vary a great deal in the way they allow others to influence them Many are self sufficient sure of themselves independent Incidentally it has always been a surprise to me that Americans, whom the world regards as particularly independent and insubmissive to authority should be so devoted to their heroes—national social and medical Despite their inveterate fondness for something new and their urge to pursue the impossible they are catholic in their search for truth and love of learning Nowhere have the famous physicians of the past and of every country been held in greater honour than in the United States

Sir James Mackenzie

May I now remind you of the life and work of James Mackenzie the centenary of whose birth occurred last year ? At the age of 25 he joined a busy general practice in Burnley a Lancashire industrial town where, for twenty-eight years he practised medicine midwifery and some surgery It was under these conditions seemingly so unfavourable for such work, that the greater part of his original observations and researches was made Up to this time neither he himself nor others had much confidence in his powers or promise, his was a brain that developed slowly The stimulus proved to be the shock of realising his ignorance, his inability to understand or deal with the painful problems that faced him daily. One such was the unexpected death in childbirth of a woman under his care from heart failure He could not understand how or why it had happened or how it could have been recognised in time Such events stirred him to discontent, and so he consulted books and journals but found no satisfaction He did not know It did not seem to be known He would find out We cannot doubt that deep feeling has often been the spring of medical research It may thus depend on a man's upbringing and character, and his devotion to an ideal So Mackenzie set to work to study common symptoms like fatigue, dyspnœa, and pain, and to learn their significance by noting their clinical course over the years Impatient only with his lack of knowledge, he patiently took notes and made records year after year with a sphygmograph and later with the polygraph he devised but in which he took little pride Here was a genius for taking pains but a common sense that kept technique in its place as a servant and not a master

---

* rom the Charles Laubry lecture delivered at the 2nd International Congress of Cardiology at Washington D C on Sept 17 1954 The full text appears in the May issue of *Circulation* published by the American Heart Association.

It had always been assumed that pain and tenderness arose directly from an organ, but Mackenzie gave the first description of hyperæsthetic skin areas associated with disease of particular viscera He showed that pain and tenderness were referred from an organ to the spinal sensory centres and thence projected to the periphery Such a "viscero sensory reflex" explained the curious extensions of pain in angina pectoris At the same time and independently, Henry Head was elaborating similar views which were published a few months after Mackenzie's

Herrick, whose death this year we lament, wrote "It was largely through Mackenzie's influence that the term 'heart failure' lost much of the opprobrium that had attached to it" Indeed it was not regarded as a proper subject for clinical investigation until Mackenzie convinced the world that the subject of heart failure was of paramount importance in heart disease, and its prevention and treatment the ultimate goal A similar revival of hope resulted from his teaching, based upon long observations on sinus arrhythmia, extrasystoles, and on murmurs which were compatible with good health In a clinical sense he isolated auricular fibrillation, at least in its relation to failure and to its particular response to digitalis

In 1902 appeared that remarkable book *The Study of the Pulse* which had no wide circulation but was quickly seized by the discerning as proof that a great investigator had been quietly at work for twenty years In 1908 came his *Diseases of the Heart*, and in 1909 *Symptoms and their Interpretation*, which together showed Mackenzie to be the most original and vigorous mind engaged in this sphere, and people began to talk of the "new" cardiology What was new was the critical, the scientific approach, and the introduction of hope into what had seemed so largely hopeless

In 1907 he had left general practice for consulting and hospital work in London In a few years he became physician to the Cardiac Department of the London Hospital, where he continued his researches and influenced the many physicians who came to his wards As years went by, he was limited physically by angina pectoris and in 1925 he died in London from cardiac infarction

What kind of man was Mackenzie to meet? He was Scottish in appearance and in accent, a massive figure with a slight stoop His bearded face, with its large brow, was carried by a large and noble head His eyes were searching, twinkling and friendly as his face was lit by a gentle smile, though not too often In general he was serious-minded and looked it, but there was a simple blunt humour near the surface Socially he was warm-hearted without being genial He was gentle in his dealings with patients, especially women, more exa towards his assistants, yet appreciative Thus he wa mightily pleased with his first resident, soon to be k in the first world war, who took better polygrams th he could himself

Though not by nature of a pugnacious temperament he was a fighter for his opinions, and he had to be Th was little appreciation and some opposition from ma of the older physicians of his day I was warned of th risks I took by becoming his chief assistant What a universal change there has been in the common attitude towards what is new, when it is true, and for this I believe we have largely to thank the Americans!

Mackenzie, you will have gathered, found it hard to be satisfied, yet it was a calm and hard headed man wh carried that unquiet and inquiring mind More, he wa a happy man, secretly gratified by his achievements and their recognition, proud to have such friends as Cushny Keith, Allbutt, Osler, Wenckebach, and Thomas Lew and constantly sustained by the deep and abiding affection which existed between him and his wife

Specialism

The second of my three subjects is specialism and the training of the cardiologist

Specialism has been called the growing point of knowledge, and it is to specialism, disintegration in a sense, that the splendid advances of the last half-centu have been mainly due Though many have opposed i notice that no one has encouraged specialism, inde that would be superfluous in so natural a process remember well the time when medicine was held to be indivisible, and cardiology was not regarded as integral branch of it The word cardiologist was not use, or it was used unkindly, whereas today a cardiologi claims to be as truly a physician as any other The stoc criticism was that specialism engenders a narrowness view, bad for the doctor himself and for his patien But, as Hughlings Jackson said "There is no harm studying a special subject, the harm is in doing kind of work with a narrow aim and a narrow mind" cardiology, as in other branches, a new and broade outlook has developed, it becomes more and mo general The true specialist looks anywhere and every where for the means of cure and prevention All the physical, mental, and social factors relevant to his ow subject are considered and integrated by him as they never were before

In some quarters there are still attempts to fo trained and mature men to abide by the past custom claiming acquaintance with the whole of general medici But many young physicians are attracted by the wi scope and variety of service which a special study of th circulation and its diseases offers Medicine has divid It already has children—the present specialties, now the grandchildren, the subdivisions—perhaps to future specialties—are growing up around us Nor parents take pride in their offspring and are particula tolerant towards their grandchildren The subdivi or differentiation, which has come to pass in medi as a whole, is now affecting us in cardiology An inst is vascular disease, and the programme of our cong proves the fact, for it is full of diverse subjects or specialties

As a cardiologist, my personal attitude towards furth specialisation can be simply stated Each individ should be allowed to make his own choice, as he did w he chose the profession itself Naturally he will seek consider advice from his teachers though he is no at school He may misjudge his own ability or the for his particular endeavour, but he has a right to ch the road he will take A wise man—and that could a young man—should recognise his limitations, bu must follow his bent The public is aware that scular disease is predominant in human mortality edicine has always been influenced by public opinion nd patients will surely claim the services not only of neral cardiologists but also of special cardiologists who ave exceptional experience in one variety of circulatory sease.

raining the Specialist

The serious danger of specialising too early is universally dmitted and it is effectively disallowed in our institu ions But how long should the training in the sciences nd in general medicine be followed after graduation? Dare I suggest that for the future specialist it may ometimes be too prolonged? Life is short For how ong should an ophthalmic surgeon restrict himself to eneral surgery and for how long should a young urgeon remain in general surgery before concentrating is powers and gaining experience in cardiac surgery? imilarly a young physician—adequately trained as uch—may prejudice the fullness of his career if he post pones for too many years the plunge into what is to be his ife-work. So let us give greater individual choice as to hich branch of medicine he favours and even, with the afeguards already mentioned as to what stage in his areer he begins to specialise. I would hesitate more to ake this unorthodox suggestion that specialisation may egin too late if I did not know that there is often a ome-back a natural return to greater commerce with eneral medicine as a man proceeds in his career

ompulsory Research?

Happily there are plenty of men you cannot keep om original research almost or actually bloodthirsty their pursuit of it others only need putting on the cent and they're off on 'the track of Truth" But ust every ambitious graduate be forced by custom or uthority to prosecute research in order to obtain a niversity post or to succeed as a practising cardiologist? esearch ability used to be regarded as a rare gift some hing of a phenomenon. It was search with some prospect f finding; it connoted both a spirit of curiosity and a apacity for investigation That is not the attitude day, though one must admit that it is largely the pansion of organised research that has transformed edical practice My question concerns the universality the capacity for research and I almost believe that e true investigator great or small is born not made hat famous literary physician Sir Thomas Browne, rote: 'Every man is not a proper Champion for Truth r fit to take up the Gauntlet in the cause of Verity' ere is a matter of policy and procedure in our profession hich will have to be decided. In my view we encourage od men inapt for original research to sacrifice their me and energy upon it when they should be perfecting emselves as bedside physicians Are we losing our sense proportion exhilarated by the wonderful products of cent and current research? Is a born investigator a perior being to a born clinician and teacher? He may may not be Advances in medicine comprise two parate stages: first the discovery of something new d valuable as a result of investigation secondly the plication of that new discovery to the benefit of the dividual patient The same man may not be the right e for both stages though he can be

Though commoner than aptitude for research the wer to apply new (and old) knowledge judiciously is t given to everyone It also requires a gift—namely inical judgment This will ripen to clinical wisdom ly by constant association with the sick Young ysicians of this type—so badly wanted—need to keep emselves abreast of the world literature in their ecialty, and devote time to postgraduate clinical work other centres and in other lands Must they invariably forced to shorten the time required for this large rpose to participate in minor and often ephemeral research before they are considered for any important staff appointment as a teacher or consultant? Not every young physician or cardiologist should be under compulsion to prosecute individual research in order to succeed.

It would not be surprising if the magnitude and the magic of recent advances went to our heads The secret places of the heart are probed or rendered visible. The blood is directed where it may run and under orders when it may clot now even its channels are to be kept clear of their silt But after all scientific truth is dis covered not created by us and knowledge is not always progress Some will remember the warning given by Professor Laubry at the European Congress of Cardiology in 1952 about the peril of technical dogmatism and the need to retain a measure of salutary doubt There is always a limit to scientific certainty in medicine, and some humility of approach is therefore becoming In fact, it is probable that we are producing both truth and error as our forbears have done The circus theory of auricular fibrillation for example seems to have come and gone but happily no patient has been allowed to *suffer from this physiological disaster!*

Research Applied

The original worker in research is fully aware of the importance of his subject and cannot be held back Are we as aware of the immediate importance of that other pressing duty that of applying the safest and soundest treatment to the sick of today? I mean getting it applied more certainly and more universally If our minds are possessed by the greater things research will do for them in the problematical future, we may be less mindful of the mass of human illness requiring our best endeavour today The vision of new truth should not blind us to our bounden duty as doctors Any hospital may be proud of the amount of research being conducted within its walls But it should be equally proud of a reputation for applying—in current practice to the patients under its care—the sum of accumulated knowledge, the best treatment in the world today In this connection may I venture the opinion that the governing bodies of teaching hospitals would be wise to retain on their staff and value the services of an adequate number of practising physicians These should not be sacrified at the altar either of science or of uniformity with loss to medical education and to the community Indeed, a medical staff will never be uniform, and the establishment should always be flexible enough to fit the exceptional individual and the late-developer and to take full advantage of any new perhaps unexpected, discovery

Unity and Friendship

I have touched on several problems for which, I doubt not solutions will be found or will naturally emerge Meanwhile we must be prepared for change willing to allow our younger gifted men freedom to strike out on their own lines according to personal inclination and judgment The call is to adapt ourselves to the changing form that cardiology is taking rather than to attempt to maintain its earlier compactness or to keep a strict symmetry in our organisation If only we cultivate the good feeling so evident at our congress we need have no fears for the future. Most of all the bond of unity will continue to lie in the grandeur of our purpose—namely the prevention relief, and cure of cardiovascular disease

When one speaks of unity and of leadership your thoughts will go at once to the president of our congress Dr Paul White Friendship for a country rests largely on personal friendships with its citizens. On that basis though not solely I would pay my tribute to the lead taken by the United States in the realm of cardiology and also give thanks for the close friendships which have bound me to this great country He spoke of hero worship, and Paul White remains one of my abiding heroes A counterpart to Osler in medicine, he has been an ambassador of good will and good hope to cardiologists all over the world He has made many original contributions, and by means of his famous book he has proved a trusty unseen consultant to countless doctors In it he has reverently combined a choice of the past with the best of the new

The French Contribution

Finally I want to say a little about the course of cardiology in France in recent years Following Potain there has been an unfailing sequence of distinguished cardiologists among French physicians First came pure clinicians like Merklen and Huchard, but it was the work of Vaquez, who combined the traditional French *clinique* with the physiological methods and researches of Marey and François Franck, that marked the beginning of contemporary French cardiology Apart from Laubry himself, to whose achievements I will return, we record with admiration the fine influence of Clerc, the brilliant observations of Gallavardin of Lyons in clinical cardiology, and the example of Giraud Then I would draw your *attention to the constancy and the quality of the work of* Professor Lian, a physician remarkable for his clinical discernment These have been followed, in strength, by Souhé, Lenègre, Froment, Heim de Balsac, Routier, and others

Inspired by the work of Helen Taussig and Blalock, and by their auspicious visit to Paris in 1947, Professor Donzelot and Professor d'Allaines, physician and surgeon, have combined in the last few years to make an important contribution from the cardiac centre at the hôpital Broussais This year, that work has been published by their brilliant co-workers, in particular Heim de Balsac, as a *Traité des maladies congénitales*, a large volume richly illustrated, and perfectly produced That is true also of another up to date French treatise for reading and reference, *Électrocardiographie clinique* by Lenègre and his colleagues

The contributions of France would be more widely evident today if it were not for the unfamiliarity of the English speaking countries with that graceful language We should all gain by a hearty understanding with France, a medical *entente cordiale* The place of France in the civilised and cultural world cannot be shaken by the passing effects of war or by political vicissitudes

Too often Paris has been solely a place for sightseeing and gaiety, and that was largely true in my own case On an early visit, however, I was privileged to go round the wards with the great Vaquez, who was attended most devotedly by his *chef de clinique*, no other than Laubry himself As Evan Bedford has said, " The great traditions of the Paris school of cardiology have been handed down in direct line from master to pupil for over a century, starting with Corvisart and passing in turn to Bouillaud, to Potain, to Vaquez, and finally to Laubry " Tradition may be a source of strength and a justification for authority To Laubry was bequeathed that authority and we realise today how valuable it has proved for the continuity of French cardiology under the trials of recent years Notice that he has been content to make this branch of medicine his life work, and the chair of clinical cardiology in the University of Paris was created for him

To begin with, he has been a brilliant clinical teacher, directly influencing students and graduates from the whole continent of Europe and elsewhere Lenègre has described those fascinating bedside clinics by the *patron* as reaching the unity and the charm of a *cardiological* ballet—though he allows that sometimes there might also be a display of fireworks !

Then since 1936 he has been the director of the *Arch* [illegible] *maladies du coeur*, founded by Vaquez in 1908. In the following year, he founded the Society of Cardiology Lastly, he has steadily tributed original research by way of clinical intuition synthesis combined with precise laboratory methods The work of his pupils bears testimony to his leadersh and the important theses produced year after year und his direction indicate the scope of his interests and h capacity for guidance His son, Dr Pierre Laubry, h also made valuable contributions

Professor Laubry has methodically assembled his knowledge in book form In 1921, he published Pezzi, a treatise on congenital heart disease In 1 appeared his famous *Leçons de séméiologie cardiovascu* and in 1930 his large textbook on heart disease O of his favourite subjects has been gallop rhythm, which he wrote, with Pezzi, a valuable monogra Interested by Vaquez and Bordet in cardiac radiolog he instituted with Chaperon a long and painstak research on the radiological anatomy of the heart great vessels, normal and pathological, using ra opaque injections The results appeared in two la volumes in 1939, *Radiologie clinique du coeur et des vaisseaux* by Laubry in collaboration with Cotte Routier, and Heim de Balsac *It has provided a scienti* basis for cardiovascular radiology ; in particular, t composition of the vascular pedicle and the lung shadows was elucidated , and you will remember concept of the small aorta—large pulmonary artery 1950 appeared the second edition of *Les maladies coronaires* with Souhé, a comprehensive and mod textbook In the same year, to the amazement of thos who had not appreciated the depth of his scholarship, for he carries his learning lightly, came his own tra lation into French of William Harvey's *De motu cor* (1628) We in Britain especially value this tribute fr one we are proud to number among the fellows of th Royal College of Physicians which the illustrious Harv himself adorned

The outcome of a man's life may be measured by ratio between his natural gifts and opportunities, and th service that he dedicates to the common good You w agree that it is not only his talents but the use he h made of them that has won for Professor Laubry th unique position in the cardiological world He posse all the elements of greatness, and they are still after an unusual experience in living, for he has pa his 80th year *In his long pilgrimage*, by teachin research, and personal example, he has set himself quicken and confirm progress in the wide realm of car vascular disease, so that he has provided a verita pattern of leadership

---

PREVENTION OF JUVENILE DELINQUENCY

Two types of children come before the juvenile co —mischievous young law breakers and unhappy prob children Sir BASIL HENRIQUES, who classified them this way when giving the Peter Le Neve Foster lect at the Royal Society of Arts on April 27, finds weakest part of child-welfare work in England to be preventive side

Many of the children born between 1939 and the of the war were separated for years from their pare and lived among strangers When the time came return, their mothers had become strangers and som times the children now had less liking for their mot than for the foster-parents they now had to leave Wh their fathers came back from the Forces they too become strangers—*not only* to the children but times also to their mothers and the strangeness of parents to one another was as devastating to the chil- as their own strangeness to their parents Some of mothers had acquired new interests and did not welc back with the love and enthusiasm about which had been long day-dreaming and some of the rs brought an almost military discipline into the e, while some were over indulgent The war, in fact uced not only many problem children but many lem parents

e mischievous young law breakers Sir Basil finds ordinary boys with plenty of initiative and courage no proper outlets for their high spirits (This has the experience of other observers: John Barron s[1] noted that Liverpool boys often commit offences ly because they need to prove their courage to one her) Only some 46% of those committing crimes is country are detected, and every young delinquent rally expects to be among the 54% who are not ht Three things, Sir Basil suggested are needed revent those crimes of adventure: first a police brought up to full strength and with better methods etection secondly enough playgrounds and sports nds for children and young people; and thirdly ortunities for them to spend their leisure in a useful constructive way He believes that the various youth nisations could give them such opportunities, but these organisations are chiefly handicapped by lack eaders of the right kind Pearl Jephcott,[2] however er study of membership of youth clubs found that about 1 in 3 children join clubs—and these are not ssarily the children who would profit most from n. Green spaces sports gymnasium and boxing ht attract more of those who now fail to join but at ent few youth organisations can offer all these things

THE UNHAPPY CHILD

ut it is not in Sir Basil s view, the adventurous child much as the unhappy disturbed unsettled child who ents problems to the juvenile courts Lack of rdination between the various agencies dealing with rived and difficult children often results in failure to e action as soon as anything amiss is noticed in child amily He spoke warmly of the example of New South les where every aspect of child welfare comes under ministry which has concentrated on preventive rk Juvenile welfare in our own country is parcelled among the Home Office and the Ministries of ucation Health and Labour

Abnormal behaviour in a child nearly always means t he is unhappy at home and many people have the nce to see his symptoms—the health visitor the ing manager the staff of the nursery school or day sery his teachers in his primary and his secondary ools the leader of his play centre his officers in the bs and Scouts his club leader the youth employment ficer and (at every stage) his neighbours Some of se watchers are bound to realise when all is not well th him; but they are not clear what to do about it d often nothing gets done

He quoted the case of two little girls now aged 5 and 6 ose mother had died two years ago and whose father had en as his second wife a girl who had absconded from a ony of mental defectives Since there were now two rents to look after them the children (who had been in the e of the local authority) were sent home The teachers their school noticed that they lost weight and seemed iously hungry and put them on school dinners. In the ter weather at the beginning of this year they came to school ly shod and in cotton frocks. They often said that they re frightened of their father and asked leave to keep their ts at school lest he should destroy them One afternoon y cried hysterically and refused to go home and their cher called in the police and had them brought before the rt as in need of care and protection

Thirteen months earlier the health visitor had referred case to the National Society for the Prevention of Cruelty to Children; and neighbours had also reported to the society that the children were never allowed to play in the street but were confined in a small back yard where there were rats If they were naughty they were put in a corner of the yard, and, if they moved the dog of which they were terrified was let loose

Sir Basil pointed out that the children's officer the school care committee, the education department and the after care officer for mental defectives (who was supervising the stepmother) all knew about this family yet these children had been allowed to suffer for many months without remedy

A CHILD WELFARE OFFICE ?

He suggests that we should establish in every town and in every district of cities, a child welfare office to which anyone concerned about the well being of a child can go for advice and guidance It should be a building worthy of its purpose presided over by the children's officer as director of child welfare and it should contain the headquarters of all the statutory and voluntary bodies which deal with the welfare of children This is no mere dream, for in Manchester many of the voluntary agencies concerned with children already have their offices in the same house The juvenile court he thinks should hold its sessions in a room in the child welfare office—a suggestion which would not win the support of C A. Joyce headmaster of the Cotswold School, who believes that the juvenile court ought to impress the child, not give him the idea that whatever antisocial thing it was he did hardly matters. The great advantage of housing all the welfare agencies under one roof of course is that a family needing help can be referred at once to the appropriate body Thus parents persuaded to consult the probation officer could do so on the spot before their moderate ardour for his advice had time to cool

FAILURES IN PREVENTION

One great weakness in our present system Sir Basil thinks is the relatively slight attention we pay to absenteeism from school yet this is a sure sign of something wrong somewhere School inquiry officers are among the most poorly paid of local authority servants They should he suggests be highly trained family case workers employed not by the education but the children s department and it should be their job to discover the real reasons why the child is staying away—the negligence of the mother or her demands for the child s services in the home or the child's own failure at school which has led him to play truant Moreover if he was a trained child welfare officer teachers would tell him not only about absentees but about children sent to school dirty or persistently late children showing behaviour problems, and children, lately cheerful who have become sullen and morose

Sir Basil spoke of our failure to prevent some of those who leave borstals or approved schools from committing further delinquencies—blaming a system which reforms the child and sends him back to the unchanged home conditions under which he broke down Work on the family of a child or young person committed to a school or borstal,' he says, should commence the very day he enters the school. He proposes that all children under 15 who need residential training should be committed to the care of the local authority this would place the local authority *in loco parentis* until the young person reached 18 Approved schools for children under 15 would under this arrangement become members of a pool of ' residential schools' ; and the local authority could send the child to the school appropriate to his needs—whether it was one specialising in delinquents or an ordinary school As no authority would wish to have more children in care than necessary, there would be an incentive, at present lacking, to get the home improved as quickly as possible This proposal has all the charm of orderliness , but it is hard to be sure that the irresponsible parents would really benefit from having their duties taken over by the local authority , or that the child would gain in security from learning that he was no longer under the control of his parents It is a situation calling for much careful thought

A MINISTRY OF JUVENILE WELFARE ?

Finally Sir Basil would like to see the children's department of the Home Office, the Ministry of Education, the National Youth Employment Council of the Ministry of Labour, and the department of the Ministry of Health which deals with children of school age and under, combined to form a Ministry of Juvenile Welfare, *a minister of Cabinet rank* This idea too has attractio its weakness is that it separates the child's situation that of the family as a whole—and this, as we are and painfully learning, cannot be done Perhaps one towards a coordination of services is to begin at the ot end, as the *Times* (April 28) suggests, by training a set of "general-practitioner" family case workers, replace the multiplicity of inquiring people now visiting the homes of families with problems Like her counter in general medical practice, she would be able to ca just the agencies which could help, thus coördinat their efforts from the start.

Public Health

THE POLIOMYELITIS-VACCINE CONTROVERSY

FROM AN AMERICAN CORRESPONDENT

The announcement on Franklin D Roosevelt's birthday of the effectiveness of the Salk vaccine in protecting against poliomyelitis was greeted in the United States with great satisfaction both by the lay public and by the medical world Since then there has been a tremendous hullabaloo which has been and is being stoked up by the press, radio, television, and the Poliomyelitis Foundation For one thing, there has been an argument about the distribution and use of the vaccine, and this has been engaging the attention of the United States legislative bodies, organised medicine, the trade unions, and the pharmaceutical houses The public want the vaccine "for free" (as they say) they have contributed generously year after year to the March of Dimes fund of the Poliomyelitis Foundation and they feel that they have bought their share of this advance On the other hand, the pharmaceutical firms need to recover their investments and wish to make a profit for their stock holders, while doctors, with no national health service behind them, quite properly want to charge for giving the injections

Much more disturbing was the announcement that poliomyelitis had developed in a number of children who had had vaccine prepared by the Cutter Laboratories, and this vaccine was withdrawn from general use While the facts and the possible explanations have been presented at length in the press, a much quieter scientific controversy was going on, and this has been brought into the limelight at the annual meetings of the American Society for Clinical Investigation and the Association of American Physicians which were held last week at Atlantic City Dr Jonas Salk and Dr Albert Sabin have long held opposing views about vaccination against poliomyelitis For many years they have presented their hypotheses at medical meetings , but this year they came up with facts, and it looks as though Sabin may be right He favours the use of attenuated-virus vaccine given by the natural route of infection (by mouth), while Salk believes that formaldehyde killed viruses given parenterally will produce antibodies as effectively as and more safely than modified living viruses Sabin has contended that intramuscular injections of killed vaccine will not confer lifelong immunity and that it would be impracticable to re vaccinate each time the short lived artificial immunity runs out If children received such a short term vaccine, he argues, there would soon be a population of young adults with no protection against poliomyelitis , and as the disease is more severe in adults than in children, a vaccine which confers only a short immunity might eventually result in many severe illnesses when [illegible]dren grew up This situation is already developing for a different reason in the United States Great Britain, for example, where standards of hyg are high and natural infection is therefore relati uncommon The exact duration of immunity confe by the *formalin killed* vaccine cannot yet be known. Salk has suggested, on the basis of studies on a lim number of subjects, that the immunity will be life-lon

Salk's short paper given at the annual meeting of American Society for Clinical Investigation was his *presentation of data collected from last year's huge* test of the action of polyvalent vaccine in prod antibody in children Three serial injections were g and antibody titres were measured at frequent inter before, during, and after the vaccinations The first vaccinations were given close together, and the or "booster" injection a variable time later Sa found that the immunological response to poliomy virus antigen in man was made evident by two measu reactions—the antibody response itself and the sta hyper reactivity to subsequent antigenic stimulation. the hyper reactive state there was a shorter inte between provocation and secondary antibody resp and the secondary response was very much greater th the primary one The degree of the secondary resp was shown to be influenced by the intensity of prim stimulation, the intensity of the secondary stimulat and especially by the interval between primary secondary stimulation The full secondary effect in could not be elicited unless the secondary stimulat was given several months after the primary inject These factors were also found to influence the degre which the serum antibody levels tended to pe Immunological response in man, following injection non-infectious poliomyelitis virus vaccine, was affe by previous immunological experience with one or of the three types of viruses, responses being striking with previous exposure to type III virus. also suggested that the presence of *measurable* amo of circulating antibody in children may not be an esse prerequisite for immunity to paralysis In some chil no antibodies were found in the blood , yet they respo to the primary injection by a rapid rise in antibo which persisted in the blood It seemed clear that t children had been previously exposed to natural p myelitis without getting paralytic disease Salk sp lated that the hyper reactive state was an impor protective mechanism against natural poliomyelitis. believed, on the basis of this work, that natural rea tions with poliomyelitis after invasion through natural portal of entry, will stimulate promptly formation of antibody and thereby limit deeper inva or further multiplication of the virus The ex question of life-long immunity could not be answe at present

Sabin, who is director of the research unit of Children's Hospital of the University of Cinc Medical School, presented his investigations to the A ciation of American Physicians He has devel *mutant attenuated strains* of virus which, when g himpanzees by the natural oral route provoked the elopment of antibodies in the circulating blood and erred 'life long' immunity to the three types of lytic poliomyelitis virus The chimpanzees had no gnisable illness as a result of exposure to the atten d virus and these viruses have never reversed their ations to reappear in the virulent paralytic form for chimpanzees Sabin described a dramatic experiment 1 20 young volunteers in the Federal reformatory at llicothe, Ohio Varying doses of living attenuated is were given to the men in a drink of milk and ibody titre was measured serially Repeated cultures e collected from the mouth throat and fæces tibody formed rapidly, and has so far persisted in blood Virus could not be recovered from the mouth, was recovered from the throat and fæces With ge doses of virus the stools have remained positive up to three months The minimal dosage was 01 ml of the pure culture This amount of virus voked excellent antibody response when swabbed on throat of the volunteers. No illness appeared in any the volunteers nor in the men who were in close tact with them in the reformatory Sabin stated t when comparative studies had indicated the best ains to use, it would be possible to determine whether not the optimum attenuated poliomyelitis virus—her given in milk or simply swabbed on the throat—ld be used for primary immunisation or for production an effective type of immunity in individuals temporarily tected by natural antibody or non infective vaccine

It was clear that many doctors at the meetings feared t the public had been too readily convinced that liomyelitis had been conquered For there are many ering facts for example quite apart from any estion of infective batches of vaccine many vaccinated ldren will get poliomyelitis for the Francis report de no higher claim than that the vaccine was effective 60–90% of those who received it

Issue of American Vaccine Suspended

Further supplies of poliomyelitis vaccine will not be ued in the United States until an inquiry into manu turing standards and safety tests has been completed nouncing this on May 6 the Federal Surgeon General, Leonard Scheele said that the vaccine was still ing produced but Federal approval of additional pplies was being held up for several days.[1] Scheele was testifying before the banking committee the House of Representatives on pending bills that uld give the government power to control the price d distribution of the vaccine. He was confident that experts now examining the situation would conclude at the vaccine was excellent and that vaccinations ould go on It would be decided in the next few days ether the vaccine would continue to be tested by spot ecks as at present or whether every lot should be amined Dr Scheele said that on May 6 the total cases of poliomyelitis in newly vaccinated children s 41 of whom 38 had been given Cutter vaccine ked whether this vaccine was now suspected he olied : We have to have a lot more evidence before could decide [2] Since April 1 he said there had en 389 cases of poliomyelitis in the United States, mpared with 423 in the same period last year

In a report issued two days later Dr Scheele announced at a detailed reappraisal of each lot of vaccine already eased or in final stages of production was being dertaken[3] He hoped that vaccine would be available use again by the end of this week There had been cases of poliomyelitis among more than 5 million ople vaccinated, and if only 1 in almost 700 000 ildren inoculated with vaccine from companies other an Cutter Laboratories had incurred paralytic polio yelitis Dr Scheele added this meant there was every ason to believe a product of the other manufacturers is safe He said there was a definite association between the Cutter vaccine and the cases of poliomyelitis that had developed after its use So until the precise cause was found the vaccine produced by this laboratory would remain suspended

The Medical Research Council has sent a member of its staff to the United States to obtain first-hand information. This should be available before the routine safety tests on the present batches of vaccine are completed and therefore before any proposed trial in this country is due to begin Meanwhile, the council will continue with the arrangements for starting the trials.

Cadmium Poisoning

The industrial diseases subcommittee of the Industrial Injuries Advisory Council is considering whether cadmium poisoning should be a prescribed disease under the National Insurance (Industrial Injuries) Acts, and if so for what occupations. Industrial injuries benefit can already be claimed for acute cadmium poisoning as injury by accident. The committee are inquiring into the possibility that prolonged exposure to cadmium at work can give rise to chronic ill health against which insurance cover should be provided Persons and organisations interested in the question of prescribing cadmium poisoning are invited to submit written evidence Communications should be addressed to the secretary, Industrial Injuries Advisory Council, 10, John Adam Street, London, W C.2 to arrive not later than June 6, 1955

Medicine and the Law

State of Doctors' Surgeries

Two decisions by the London Executive Council at its meeting on April 28 concerned the duty of practitioners under the National Health Service to provide and to permit the inspection of proper surgery accommodation Clause 7 (4) of the Terms of Service requires the practitioner 'to provide proper and sufficient surgery and waiting room accommodation for his patients having regard to the circumstances of his practice Clause 7 (5) provides that on receipt of a written request the practitioner shall at all reasonable times admit any member or officer of the council or the local medical committee authorised by the council for the purpose of inspecting the surgery or waiting room.

In the case of Dr A an inspection was made in February, 1955

Dr A's surgery hours were from 11 A.M to noon but when the inspecting officer called at 11 40 A.M., Dr A who apparently slept in the consulting-room was not ready

---

1. *Times* May 7 1955.
2. *New York Times* May 7 1955
3. *Times* May 9 1955

to receive patients In the waiting room was a quantity of old paper, a dilapidated leather trunk and a tin box The consulting room was in a state of muddle - The floors had no covering and had not been swept The visit was paid when there was snow on the ground, but there was no evidence of a fire in the waiting room, although Dr A said that a fire was provided when required There was no running water in the consulting room and no light in the lamp holder in the waiting room, and in both rooms the windows and curtains were dirty

Dr A was invited to submit observations and to attend a meeting of the medical service committee He failed to do either The executive council adopted a recommendation that representations should be made to the N H S tribunal that the continued inclusion of the practitioner in the council's medical list would be prejudicial to the efficiency of the service

The case will now be subject to inquiry by the tribunal

In the case of Dr B the local medical committee had asked for an inspection of the surgery and authority had been given by the chairman of the council

Dr B agreed to receive the inspecting officers and the hearing was fixed for March 11, 1955 Dr B subsequently wrote stating that the date was inconvenient as decorations to the premises had not been completed and the council to defer the inspection until the middle of The council replied that they had not asked that the should be re decorated before inspection. Dr B was that the duty of the inspecting officers was to report to council on the present condition of the premises and that information he gave as to re decoration &c, would incorporated in the report The apparent reluctance of doctor to permit the inspection of the premises was to the notice of the appropriate committee on March and on the following day the doctor was notified that committee had decided to refer the matter to the med service committee unless he indicated several days the ensuing fortnight on which the surgery could inspected No reply was received from Dr B

The medical service committee considered that had shown a complete disregard of his obligations the Terms of Service and they advised that a recom mendation be made to the Minister of Health the sum of 30 guineas be withheld from his remunera The executive council adopted this recommenda which is subject to appeal

Parliament

Review of Social Services

IN the House of Commons on May 4 Dr EDITH SUMMERSKILL, in opening a debate on the social services, regretted that the report of the Phillips Committee on the economic and financial problems of the provision for old age, had been ignored by the Government She pointed out that the new scales would not help the old-age pensioners on National Assistance Of those on sickness benefit 123,000 would only get 2*s* 6*d* extra, and most of the people receiving this benefit were the chronic sick This led her to ask the Minister of Health if he was satisfied that, having regard to the hardship it imposed, and the administrative burden it entailed, the shilling prescription charge should be continued? Had the Minister inquired in districts where industrial processes had a deleterious effect on the workers' teeth to see whether withholding a free service had resulted in a deterioration of dental health? She understood that £50 million was spent annually on drugs, 30% of which went on proprietary drugs She found it difficult to understand how the Minister could allow this huge sum to go on swelling the large profits of the big drug houses, knowing how cheeseparing he was in other directions The Minister had been trying to persuade doctors to use cheaper alternatives, but he had done everything except take strong action He should refuse to sanction unnecessary expense in prescribing when there was a satisfactory alternative

Mr IAIN MACLEOD interposed that Dr Summerskill's suggestion might infringe the right of a professional man to decide what, in his judgment, was best for his patient Though advice had been given to doctors that certain drugs were not of proven therapeutic value, if a doctor in his own discretion still decided to prescribe one of them it was perfectly legitimate for him so to do

Dr SUMMERSKILL went on to ask if the Minister thought he was justified in allowing hospital beds to be earmarked for fee-paying patients when in some districts there were long waiting-lists, and whether he could report any improvement of conditions in our mental hospitals

Mr OSBERT PEAKE, Minister of Pensions and National Insurance, described the Phillips report as "most valuable" and said that it was clear that as a result of it there would have to be legislation at a later date amending the National Insurance scheme But he thought the scheme was a good one and he would be reluctant to introduce changes into it just for the sake of changes He had been assured by the National Assistance Board that the increases in February had fully restored the loss of purchasing-power of the allowances which had occurred since June, 1952 In July, 1948, the Assistance Board were paying 842,000 allowances, that figure had risen by the end of March, 1955, to 1,807,000 increases in pensions would reduce by 100,000 the num going for assistance

Mr KENNETH ROBINSON returned to the case of boy with a fractured and dislocated arm who had wa at Hampstead General Hospital for more than six before he received medical attention Mr Rob had found the Minister's reply about this case satisfactory[1] But the matron immediately began give interviews to Press reporters in which she said she had not heard of anyone being reprimanded explained that the boy had been kept waiting for hours because it had been impossible to get a spec in the hospital sooner, and that he had not been food or a sedative because he was to have an anaesth Mr Robinson shared the great respect and gratitude the House and the country had for the nursing profe but it seemed to him that some members in the hi ranks of the profession were rather resentful of crit The matron of this hospital had in effect repudiated Minister's apology and Mr Robinson felt that the could not be left there

Mr MACLEOD agreed that Mr Robinson was to raise this case in the first instance and, in view of statements which had been made, he was wholly rig raise it again He, like Mr Robinson, had hoped with the full apology which he had made on behalf the board of governors, and in particular on of the Hampstead General Hospital, the matter had closed He had been considerably startled to read in newspapers the comments which the matron had The answer which he had given to the House on was made after consultation with the board of gov and it had the agreement and encouragement of people responsible From time to time one got impression that the people concerned in these were a little reluctant to admit that they were in because they thought that might reflect upon a ho of which they were *rightly proud* In his view that a wrong attitude If a fault was found, nothing hospital more credit than to say that it was and it was right that an explanation should be frankly to the House of Commons by the Mi *responsible, as had been done in this case* hospital had slipped in one particular instance, it did mean that it was not a fine hospital with fine as he was quite certain was the case here We all adm the quality of loyalty and he could easily under a matron who was proud of her hospital and the working there resenting, perhaps a little too any suggestion that the hospital had slipped in its But what had been said was unwise and unf it should not have been said, and he was certain that matron much regretted having made an allegation he understood she had—against Mr Robinson himself

---

1 See *Lancet*, May 7, 1955, p 966

urning to the question of prescribing, Mr Macleod l that it was entirely within a doctor's discretion to scribe a particular drug even though it had been gested by the committee and Ministry that this was advisable He would not be surcharged for that was possible—and this was a different point—that his scribing as a whole might be looked at, and one element ght be the over-prescribing of one particular drug Macleod did not see how they could achieve what Summerskill seemed to have in mind which was ited to the prescribing of the ordinary substances on the list without interfering with the ordinary clinical eedom of doctors He would not wish in any way to terfere with the right of a doctor to prescribe at his scretion in individual cases The total bill for England and Wales for medicines was about £43 million not luding hospitals, and within that sum £21 million a little more than half was due to proprietary medi es. That was cost alone the non proprietary pre iptions would be more than half because the others re more expensive Many of the greatest discoveries, h as the antibiotics, had been made by private firms garding the pattern of dental treatment, Mr Macleod d that the important fact was that conservative atments had gone up from 4 070 000 in 1951 to 00,000 in 1954 that in the school dental service the mbers, which had fallen at the end of 1951 to 713, d risen at the end of last year to 979 The dental atment of the priority classes was a great deal better in it had ever been

About 1% of the beds in the National Health Service re private beds and about a third of those at any given e were occupied by non-paying patients, either on unds of medical urgency or to see that the beds were ed The proposal to abolish pay beds was a breach faith with millions of people who paid into contributory emes so that they might have some privacy in spital.

The mental hospitals had no waiting list, and the 8500 ls that were being provided were a contribution to the ef of overcrowding For the mental-deficiency pitals there was a waiting list of about 7000 5007 ls had been completed, or were nearly complete l there were also 945 beds included in the 1953–54 gramme, not all of which could be actually occupied There was therefore a programme of at least 0 beds as against a waiting list of something like 0 But the Government had recently announced substantial hospital building programme and the ntal-deficiency side would get its full share

Prison Reform

In the House of Lords on May 4 Lord PAKENHAM in ling attention to the Prison Commissioners report for 53 said that he had lately shared in an inquiry, under en on behalf of the Nuffield Foundation into the es of crime, and in the last year or two he had ited some 20 prisons or borstals. He submitted that xt to nothing was being done to reform the majority convicted prisoners indeed it might well be argued at they were likely to come out of prison worse than en they went in We were not making an effort in a direction commensurate with our degree of social lightenment in other fields

The overcrowding of our prisons—the fact for instance, at out of 17 485 in prison 2880 were still sleeping three a cell—was a sore impediment to the best intentioned ison staffs. The most troublesome bottleneck which day frustrated the efforts of all who would like to extend e training system using that word in the sense not ly of trade training but also of moral training was e shortage of staff Today the three-shift system was force in only a quarter of our prisons But without the idea of individual treatment for prisoners would main a fantasy It was a major and imperative duty ther to bring down sharply the number of prisoners to increase rapidly the number of staff

Viscount TEMPLEWOOD pointed out that only 21 000 en and women were involved Surely a welfare State ith all the immense improvement that we had seen in ery social service could deal with this small problem an urgent and common-sense manner Yet instead of progressing, so far as accommodation and work went we had fallen back 50 or 60 years. He urged that there should be an inquiry into all prisoners records to see how many of them could be allowed to work outside prison Work in prison should be useful and paid for at regular rates. The money should be allocated to the man's keep, compensation for the victims, and the provision of a sum for the prisoner when he left prison The best hope for many offenders was to make them work and make them take an interest in it Lord MOYNIHAN suggested that there should be compulsory aftercare for boys of 14–17 who were sent to detention centres He would like to see the system of ' home leave extended and given not only to those who had happy homes but also to the homeless He was sure that carefully selected families would be prepared to take these boys in the first weeks of their probation The appointment of permanent welfare officers in prisons would be a great step forward

Lord MANCROFT, joint parliamentary under secretary of State for Home Affairs, said that the prison and borstal population in 1930 was 10 000 and by 1952 at the peak it had reached 24 000 Since then it had gradually decreased and was today about 21,000 The effect of the sharp rise was that in 1952 there were 5200 prisoners sleeping three in a cell That figure was now down to 3000 Nothing but necessity excused that deplorable state of affairs Oddly enough, this situation had had little effect on health and discipline, but it remained wholly undesirable Overcrowding was not allowed to interfere with training in specialised prisons; its effects had been confined to local prisons. The plans for new prisons were based on the bold decision to break away from the traditional walled prison and to place in open conditions all who could safely and properly be trained there. There was *no shortage of men coming* forward for posts as prison officers, but they were not always the right men Recruits were urgently needed There had been a shortage of work in the prisons, but the past year had shown improvement In all specialised training prisons there was a full working day in good class industrial work. The treatment of prisoners was now dominated by the conception of training The Government stood by that conception and believed it to be wholly right and proper

Full use was being made of the detention centres by the Courts, and it was hoped to widen the system The centres were making an effective contribution in combating juvenile delinquency Many prisoners who had otherwise been written off as hopeless had been saved from a life of crime by flexible methods of corrective training Greatly increased medical services had been set in progress since the war in local prisons, directed towards rehabilitation—particularly psychological and psychiatric services rehabilitative surgery and specialised treatment under the National Health Service, both in outside clinics and in hospitals While there was still great room for improvement there had been a great effort to improve the Victorian sanitary conditions in prisons and this effort would be continued The whole process of aftercare for prisoners other than in local prisons, had been reorganised by the formation of a Central After Care Association, and by the decision to bring in the probation officers as field workers for the association Every prisoner in the care of the association after his release was under the immediate supervision of a skilled social case-worker

QUESTION TIME

Review of Extraction rates of Flour

Replying to a question Mr HEATHCOAT AMORY Minister of Agriculture and Food said that he had decided in conjunction with the Secretary of State for Scotland and the Minister of Health to arrange for an independent authoritative review of the scientific and medical evidence now available in regard to this matter Lord Adrian president of the Royal Society had nominated for the conduct of this review the following panel of representatives of scientific and medical opinion:

Sir Henry Cohen F.R.C.P., Professor of Medicine University of Liverpool (chairman) L J Witts F.R.C.P., Professor of clinical medicine, University of Oxford J H Gaddum, SC D, M R C S F R.S, professor of materia medica University of Edinburgh A C, Chibnall SC D F R.S, formerly professor of biochemistry, University of Cambridge R A Morton D SC., F R.S professor of biochemistry, University of Liverpool

The terms of reference of the panel are

In the light of the scientific and medical evidence now available to determine the differences in composition and nutritive value between (*a*) National flour as defined in the Flour Order 1953, (*b*) flour of extraction rates less than National flour as defined in the Flour Order 1953 to which the three token nutrients have been restored (*c*) flour of extraction rates less than National flour as defined in the Flour Order 1953, to which the three token nutrients have not been restored and to advise whether any such differences are significant from the point of view of the health of the population

Poliomyelitis Vaccine

Replying to a question, Mr J R BEVINS, as representing the Lord President of the Council, said that the current programme of poliomyelitis research coördinated by the Medical Research Council might show whether there was any practicable alternative to the use of monkeys in preparing a poliomyelitis vaccine, but he was advised that an adequate substitute for monkeys was unlikely to be found in the near future for a vaccine of the Salk type It was hoped, however, that adequate supplies of monkeys would be available again shortly He could give an assurance that research to find a promising substitute was going on Before any of this type of vaccine was used in this country it would be very carefully tested on monkeys or some other animal

Replying to a further question, Mr MACLEOD said that recently reported events in America were being fully considered by the M R C, and a member of their staff was going over there immediately to get first hand information This should be ready for study here before the routine safety tests, now being conducted on batches of vaccine, were finished and therefore before any of the proposed trials on children over here were due to begin Meanwhile arrangements for these trials continued There was no intention of inoculating any child unless the full consent of the parents had been first obtained

Postal Votes

Replying to a question, Mr IAIN MACLEOD said that he had studied carefully the documents sent to him about pressure being brought to bear on doctors by local Conservative associations to send them the names and addresses of their sick, blind, and aged patients for the purposes of the postal vote It was desirable that everybody should be aware of their right to a postal vote and equally important that any information given should be made available to all political parties who asked for it There was nothing wrong in responsible citizens, doctors or others, bringing to the notice of those concerned, whatever their politics, their rights as postal voters On the specific question about extracting patients' names from doctors' lists, he would not expect information concerning doctors' National Health Service patients, which was normally regarded as confidential, to be disclosed for some entirely different purpose He was sure that doctors understood the position and that no special communication was necessary

Welfare Foods

Replying to a question, Miss PATRICIA HORNSBY SMITH gave the following figures for the distribution of welfare foods

Welfare food	1953 July–Dec	1954 Jan –June	1954 July–Dec
National dried milk (millions of tins)	12 34	11 92	11 33
Cod liver oil (millions of bottles)	3 28	3 30	2 79
Vitamins A and D (millions of packets)	1 03	1 03	0 83
Orange juice (millions of bottles)	15 58	14 81	13 41

These foods, she added, were intended for those whose diet might otherwise be deficient, and the arrangements of the local authorities were well adapted to concentrate attention on this group In the community as a whole the downward trend might well continue with the continuing improvement in the general diet and standard of living The department would maintain a close watch on developments

In England Now

A Running Commentary by Peripatetic Correspon

To conduct, control, and conclude a consultati a querulous, persistent patient is an exercise in ap personality that can be fascinating to the be although arousing different emotions in the p Medical students may study their chiefs and in outpatient departments the patients may fill the waiting time by making extensive observations on th subject I have had the good fortune to purs subject under both conditions and here pres preliminary report

The commonest method, and one lacking all cha to terminate the interview and stop all further que is " I'll write to your doctor You go round and disc it with him next week " The psychiatrist, and those wit psychiatric leanings have an altogether more diplom approach, an approach designed to act like foam on fire, to damp down and smother the burning passio and to allow those that will not be smothered to bu themselves out These experts just let the patient on talking and talking while they remain emotionle impassive, impersonal, and aloof At the end of th allotted hour they quietly make an appointment for further instalment, no doubt noting in their notes "M Next Week " Another subtle, though somewhat approach is to appeal to the patient's self-esteem by flattery This is often successful with readers of popu medicine articles You merely have to preface yo remarks with " A man with your knowledge of medic will at once realise " Another convenient form for the rushed doctor, but one liable to cause addictio and even abuse by the lazy, is the " Let-me-know-if gets-any-worse " approach This is of course not fo proof, for next week the patient may return to sa that it has become worse Under such conditions anoth line must be taken. One may assure the patient th he has a very rare, interesting complaint for which yet there is no treatment (this is much favoured b neurologists), one may keep them under observatio (a physician's gambit), or one may adopt the "Tha funny, I have the same trouble myself," and the unload your anxieties and symptoms upon the pat Oddly enough this seems to help both the patient an the doctor

* * *

We are once again in the midst of an election batt with all parties in search of the elusive floating vo and I am irresistably reminded of the last electio and Annie

Annie was one of several hundred old dears at home for the aged Never very active, she was confined to bed permanently with gangrene of foot, which she stubbornly refused to submit to surger She lay there in gloomy silence, and appeared to ha abandoned all interest in life

Which party it was, I forget, but some shrewd politi type saw in the home a happy hunting-ground for vo A fleet of cars arrived, and all those passed as "f were taken to the poll. Annie pleaded for a ride, I hadn't the heart to refuse

On her return she was in a state of considerable tion " I do hope I done right—I suppose it's all for best " The old dear commented so seldom upon thing that such concern over the election was ext ordinary Sister investigated Annie was quite sure had just given consent for her leg to be amputated

I often wonder for whom she voted

* * *

As our taxi hurtled over the perilous track to Bab we found the driver glad to talk of life in his count We passed a convoy of army trucks given by the Un States and mobile A A guns made in England, then army camp Oh yes, there was national service, he sa two years for all men—unless they paid 50 dinar which case it was three months That is official dinars secures complete exemption That is unoffici We skidded and slid in the sand, bumped, and thump our way from one mud hollow to the next, and stil smiled and joked. There was the way trucks are overloaded (nearly everyone we saw was an example) When the last bus home was full the driver sent his colleague on to the roof among the luggage. But that night it was windy and cold so he shared a coffin with its rightful owner on his way to his burial When the next man came up on the roof the living occupant of the coffin put out his hand to show he was there He went to court—not for travelling with a corpse in a coffin but for putting out his hand in such a way as to frighten the newcomer Three months jail was the price of his thoughtlessness.

"We are living in the 10th century here our driver said as our 20th-century limousine survived mile after mile of insult. Wives are still cheap 60 dinars buys the ordinary kind 100 the very best If the husband does not like her he kills her She was no good' in the law courts means no worse a penalty than two months in prison That is the law, you see." What happens if a man murders another man? we asked Oh he is hanged of course," he replied

Wives do the work while husbands sit in the cafés smoking their great ' hubble-bubble ' pipes. Toiling in the fields on either side of us through the hours of light were these poor peasant women heavily clothed in tattered black. There, too, were superb birds feeding in freedom Large green bee-eaters swooped on flying insects blackwinged stilts probed the saltings with their graceful bills a solitary flamingo stood still. 'If I d had the chance before I was born to choose what to be, I d be a bird, he said I see what he meant.

* * *

My peripatetic colleague surely cannot seriously intend that we should instruct our adult patients to Lie on the couch with your tummy upwards.' But I agree that the usual ' Lie on your back on the couch ' regularly results in a patient lying on his face The remedy came to me in a moment of inspiration: 'Lie down on the couch please. I say no more no less I have yet to see a patient who spontaneously adopts any but the supine position

* * *

Last year our rural district almanack and directory had some interesting health notes and hints for the nursery

Headaches, dizziness and shortness of breath are often caused through neglecting the feet

"Cramp generally arises from a disordered liver For quick relief from the pain the feet should be plunged into hot water and rubbed hard with a towel. If hot water is not obtainable rub in camphor liniment or embrocation.

"If a person cannot sleep it is because blood is in the brain; the remedy therefore is to draw blood down from the head. This may be done by eating one or two small onions or a biscuit

"It is harmful to force a baby to take notice The brain will develop much better if left naturally

"Paddling in the sea is a serious danger to many children. Paddling has been known to cause convulsions, cramp heatstroke and severe bronchitis

Unfortunately the publisher seems to have had a hint that the notes are a little outdated for this year they have been replaced by notes on bird life and a page of wit and humour

* * *

In bed with another overpowering cold I am feverishly wondering why this type of coryza major never afflicted me until I came to British Columbia But here of course the forest trees are enormous, the buttercups grow twice as high as those in English meadows, and gigantic salmon throng the rivers. I ought to have known that the viruses would be jumbo size

* * *

Psychiatrists must look to their laurels, for it seems that their closed shop is not so closed as they think. In the last issue of *The Lancet* I read of kidneys showing "a diffuse distal tubular neurosis Imagination boggles at the future Are we to hear of neurotic syndromes relating to all histologically differentiated regions of the body? Sorry Old Man can't play golf today, I ve neurosis of my islets of Langerhans

Letters to the Editor

BLOOD-AMMONIUM LEVELS IN LIVER DISEASE AND "HEPATIC COMA"

SIR,—In their article (April 23) Dr Phear Dr Sherlock, and Dr Summerskill have shown that the administration of ammonium chloride and methionine to two patients was followed by gross mental deterioration culminating in coma They state (p 838):

> As in case 1 *therapeutic* [my italics] administration of ammonium chloride caused the blood-ammonium level to rise before clinical deterioration took place and again recovery coincided with a fall in the blood-ammonium level. Following oral *dl* methionine a relapse was associated with a rise in the blood-ammonium level

The manner by which this information was obtained raises moral and ethical questions. No doubt the relationship between the level of blood-ammonium in liver disease and the production of mental changes is important to medicine. However, this information had already been obtained by other workers to whom reference was made in their opening paragraph (p 836) In order to prevent a premature or rash judgment on the moral issues involved would Dr Phear and her colleagues be good enough to answer the following queries

(1) Did they know that ammonium chloride and methionine were potentially dangerous to cases 1 and 2 before the drugs were administered? If they did why was it necessary to confirm the knowledge?

(2) Were the patients consulted before substances potentially dangerous to them were given and did they agree to participate in the experiments?

(3) If the patients did agree were they capable of fully understanding the nature of the therapeutic experiments and the dangers involved? From figs. 4 and 5 it would appear that they were not mentally normal before the noxious substances were administered

(4) If one of the patients had died in coma during the therapeutic trial would the coroner have been informed and given the full story?

(5) Would they have performed similar experiments on themselves or on their near and dear ones supposing they were clinically suitable?

Medical research workers who are concerned with human lives have to steer carefully between the production of fruitful work and the obligations of the Hippocratic oath In this spirit, I look forward to a satisfactory reply

Pathology Department,
Birmingham Accident Hospital

S SEVITT

*** This letter has been shown to the authors of the article whose reply follows—ED L

We are glad to answer Dr Sevitt's points

1 Ammonium chloride (in the management of ascites) and methionine (on the nutritional hypothesis) are currently used therapeutic agents in the treatment of liver disease. Our paper concerns therapeutic trials *not* experiments Ammonium chloride and methionine were administered to these individual patients in order to diagnose accurately their mental and neurological illness. As we have concluded in this paper there is no certain biochemical method of diagnosis, and transitory mental and neurological deterioration after methionine ammonium chloride or a high protein diet are the only certain diagnostic tests we know Simple protein restriction is not a certain diagnostic method for we have observed patients with chronic portal systemic encephalopathy who have failed to respond to it. The diagnosis of these complications can be extremely difficult and later experience makes us think we may have over-simplified the issue in our earlier paper (*Lancet* 1954 ii 453) Certain diagnosis can of course be followed by correctly applied treatment Trials of this nature in patients with obscure mental and neurological illnesses will prevent many being admitted as certified insane to mental hospitals We have recently known of

six such instances We also give courses of ammonium chloride and methionine to candidates for porta caval anastomosis, where the development of mental or neurological changes contra indicates the operation It is unjustifiable to perform this operation without such a preliminary trial

2 The patients were aware of the nature of the substances they were to receive (they had had them before therapeutically in other hospitals), and that it was necessary for diagnosis to determine their effect They knew that temporary mental and neurological deterioration might follow, and willingly agreed

3 They were capable of understanding the nature of the trial

4 Under conditions of careful observation by the team here (which includes a full time trained psychiatrist alert to the earliest mental changes in liver disease), the possibility of permanent sequelæ or fatal issue due to these drugs is non existent The changes are transient and reversible The coroner would of course always be informed of unexpected death during any treatment

5 If we or our relatives suffered from liver disease and had mental changes or had an obscure organic psychosis or neurological illness it would be necessary, under hospital observation to determine the effect of nitrogenous substances including ammonium chloride and methionine

Dr Sevitt rightly emphasises the moral and ethical issues involved in our efforts to diagnose our patients' ills and in attempting to define more accurately the management best suited to their needs Like other members of our profession we are constantly guided by these moral obligations to patients who have sought our help or have been referred to us as difficult problems It was this moral obligation which prompted us to report our observations in the medical press and thereby draw attention to this complex and ill-understood aspect of liver disease This may provide guidance for others in the diagnosis and management of obscure organic psychoses, prevent unnecessary certification, and possibly prevent the present abuse of a high-protein diet and other nitrogenous substances in the treatment of liver diseases

We will be pleased to meet Dr Sevitt so that we can discuss the matter more fully and perhaps show him the clinical management of patients with liver disease in this hospital

INSTINCT AND THE NURSING COUPLE

SIR,—I would like to congratulate Dr Mavis Gunther on her interesting observations on nipple protractility, in her article of March 19, and to concur entirely when she says that, in human mothers, instinct does not ensure maternal efficiency in breast-feeding

This is perhaps made more obvious by the present day contrast between the high incidence of failure in the West and the almost universal success amongst tropical peasant mothers For example, in Yorubaland in Western Nigeria, of 208 children aged between one month and two years who were investigated, all were found to be still breast feeding successfully[1] Similarly, an as yet incomplete infant feeding survey in rural West Bengal has shown uneventful and continuous breast-feeding in all of over 150 infants aged between one month and thirty months so far investigated—with the exception of a small number where death or very severe illness of the mother made breast feeding absolutely impossible In both of these surveys, a high proportion of the nursing mothers were markedly malnourished

As to the factors suggested by Dr Gunther as being responsible for success or failure of breast feeding, I would offer the following comments and additions

(i) *Instinctive response*—This certainly appears to predominate in the infant rather than the mother, but the newborn baby will have more chance of successfully making contact if he is lying on a mat by the mother's side with the breasts near at hand, as occurs with the tropical villager

(ii) *Learning by observation*—From infancy Asian and African peasant females are surrounded by women unconcernedly and unashamedly breast feeding their children, not only in the house, but anywhere and at any time of the day or night

(iii) *Psychological factors*—The Western woman frequently approaches breast feeding not only in ignorance of practical details, but often with some, at least, of the following psychologically disturbing attitudes a fear of failure (engendered to some extent by modern old wives tales), a clear knowledge that easily accessible alternatives are available (which have been drummed into her since childhood by ubiquitous advertising), a desire to return to work or social life as soon as possible, and sometimes a dislike of the whole process or even in extreme cases an alleged disgust All of these can interfere with the mother's confidence and ability, so that, as stressed by Verhœstraete,[2] the disastrous snowball effect of worry—poor "let-down" reflex—dissatisfied baby—increased worry, &c occurs, associated with a diminishing output of milk from inadequate mammary emptying By contrast, the tropical peasant woman (and her Western cousin until quite recently) approaches breast-feeding not with confidence, because this is too positive a word, but a completely matter of fact naturalness Without being conscious of it she knows from personal observation that breast feeding is a simple process carried on uneventfully, while, at the same time, her attention has not, as yet, been distracted by the advertising of artificial foods In this context, it is interesting to note that, according to Cicely Williams (personal communication) European women, pregnant when interned by the Japanese, were later all able to breast feed their babies when faced with the uncompromising reality of a Singapore internment camp

(iv) *Shape of breasts*—Dr Gunther's investigation of nipple protractility is of great interest As far as I am aware no investigation of breast or nipple shape or size has been carried out amongst tropical peasant women My impression amongst West African women was that, possibly as a result of a lack of any type of support, the breasts were somewhat pendulous even before childbearing Certainly after the first baby the breast becomes flat in the upper half and rounded and pendulous below, presumably partly as a result of uncontested gravity, so that babies can easily be fed per axilla when carried on their mothers' backs In these women the nipple protractility should, one would have thought, have been excellent and have acted as a good "sign stimulus"

It is also interesting to note that the aboriginal Juangs of India divide female breasts into different groups according to their alleged milk giving potentialities[3]—from the *latop nunoro*, which is flat like a tortoise and has a poor yield, to the *bagh nunoro*, the rounded, so called "tiger breast" which is reputed to have an abundant and easy flow One wonders whether there may be some association in this classification with nipple protractility and ability to act as a "sign stimulus"

To close this short picture of the contrast between the over sophisticated Western mother and her counterpart in the tropical village, I cannot do better than quote Matthews's excellent description of the latter as seen in Nigeria

"Her hormonal mechanism is undisturbed by anxiety complexes She is not besieged by friends, relatives, nurses and doctors advising her against breast feeding and putting her 'at the mercy of the accumulated gossip of her time' She does not receive, within a few days of confinement suggestive pamphlets from infant food manufacturers encouraging early weaning, nor is the Yoruba neurotically prejudiced against the nursing experience as being 'messy' and 'disgusting', nor does modesty prevent her feeding her baby in the markets, by the road side or, if she be a nurse, in the anteroom of the hospital ward What does she care if she lose her figure and her vein marked breasts sag near her umbilicus? Parenthood is her central interest, duty and pride"[4]

MEDICAL TELEVISION PROGRAMMES

SIR,—I protest against the programme shown on the B B C television service on May 2 Some elementary physiology was demonstrated with living subjects but the whole presentation was to me revolting At the point where a demonstrator actually burned with a lighted cigarette the forehead of a subject lying on a couch and connected with wires and tubes to recording gear, I switched the set off with the unanimous consent of my family Surely horror comics have nothing on this programme for pseudoscientific sadism

I hope there will be no more of this sort of stuff on television and that doctors will not coöperate in pandering to the crude public taste for medical sensationalism

Birmingham 15 FAUSET WELSH

HARDENED FATS AND LUNG CANCER

SIR —Dr Nyrop's further letter (April 23), erudite though it is should not be allowed to divert your readers from his original and quite unwarranted contention He has sought to show that a deficiency of essential fatty acids may be a factor in the causation of lung cancer and, more especially, that such a deficiency may be induced by the replacement of butter by margarine in the diet.

Something may be said for the introduction of new theories of carcinogenesis, in that they may stimulate useful lines of investigation But as regards the essential fatty-acid content of margarine we are dealing with fact not theory The fact is that it has been shown by animal experiment[1] that margarine contains a substantially greater amount of biologically active essential fatty acids than butter Dietary deficiency in these substances whatever its rôle in carcinogenesis is therefore *less* likely to occur when margarine is eaten instead of butter

ELECTROPHORESIS OF PLASMA-PROTEINS

SIR,—In view of Dr J A Owen's letter of April 23 I feel I should point out that results of a rather similar nature have also been observed in these laboratories details of which will shortly be published in the *Journal of Clinical Pathology* There are, however some points upon which I would like to comment

We do not obtain such distinct double β globulin bands as is illustrated by (*a*) in Dr Owen's letter, unless the serum or plasma is fresh and unless the buffer contains borate Dr Owen's result, in the absence of borate appears to be the exception rather than the rule as is evident from the great majority of published illustrations of paper electrophoresis of sera in Veronal buffer

The reason for the occasional exception is not at present clear; we confirm that the slower β globulin component is undoubtedly labile as it disappears after serum has been allowed to stand at room temperature for several hours or even after storing at −20°C for two weeks. Borate appears to exert a stabilising effect in electrophoresis, but in the absence of borate there may be other factors in Dr Owen's experimental condition which also prevent alteration of the labile component. Contrary to Dr Owen our results suggest that the labile component is converted in aged serum to one of higher mobility and merges with the normal faster β-globulin band.

In his second illustration (*b*) there is also shown a double β band, but in this case the slower component is absent and a band appears just ahead of the normal β band We suggest that this faster component is an artefact produced presumably by enzyme action on one of the β globulins since we have obtained similar results only with sera which have been aged at room temperature for long periods

Alterations in the ratio of the concentration of the two β globulin components in fresh serum or plasma may well be significant in some diseases but it is clearly important that no appreciable alteration to the unstable component should occur during electrophoresis One method would appear to be the use of borate, but in borate alone α_1 globulin has a *mobility similar to that of albumin* This disadvantage has been overcome by employing a mixed borate veronal buffer, which is now being used in these laboratories for routine investigation Full details will be published in the forthcoming paper

A MORPHOLOGICAL CRITIQUE OF TEMPORAL LOBECTOMY

SIR,—In his article (April 30) Dr Crome expresses doubts regarding the validity of the biopsy findings reported, among others in a paper by myself in collaboration with Mr Murray Falconer and Mrs Elizabeth Beck.[1]

> In this paper we discussed rather fully the difficulties inherent in the interpretation of biopsy material, and we had taken care to reduce the element of ' subjectivity by controlled serial investigations We also admitted to being inevitably handicapped by not knowing whether similar changes are found in the unoperated temporal lobe or in other parts of the brain In our conclusions which were mainly concerned with aetiological problems, we stressed the preliminary nature of our report and the importance of systematic post-mortem studies of clinically and electrophysiologically well investigated cases of temporal lobe epilepsy as ' they are bound to give a more comprehensive and clearer picture of the histological changes than the investigations of isolated biopsy specimens so difficult to interpret could ever provide '

Such post mortem studies on an adequate scale will naturally take some time to mature Dr Crome's otherwise important and interesting material is deficient *in this respect* since on his own admission no reliable information could be obtained on psychomotor phenomena hallucinations, and auras owing to the severe mental retardation in the majority of his cases.

The histological abnormalities in our material of 18 cases were severe in 11 consisting either of focal lesions (circumscribed tumours and vascular malformations) or of diffuse cortical and white matter sclerosis Partly overlapping with these cases Ammon's horn sclerosis was found in 7 (not 5 as Dr Crome stated) out of 12 cases in which hippocampal tissue was available for study Dr Crome dismisses Ammon's horn sclerosis as a merely secondary phenomenon due to severe grand mal or other types of anoxia Although we agree with this view (as we have been at pains to point out in our paper) this does not preclude its primary significance in the clinical manifestations of temporal lobe epilepsy Evidence has been accumulating particularly from experimental studies that Ammon's horn and the neighbouring uncus and amygdaloid complex serve general visceral function and have some relation to behaviour particularly emotional behaviour Their pathology in cases of temporal lobe epilepsy requires, therefore our earnest consideration

In only 4 of the 18 cases doubtful and uncertain pathological changes predominated although even in these some positive findings were recorded There is thus in our material considerable variation of the pathological changes both in quality and quantity as we stated in our paper Should these be causally related to the clinical manifestations of temporal lobe epilepsy this relationship would not be a simple one Perhaps we did *not* sufficiently emphasise this complexity in our *preliminary* communication but it has been given attention in our more recent publication[2] in which we discussed the possible significance of a genetically determined epileptic factor and of an unspecific *effect* of the operation by removal of not necessarily diseased centres and interruption of neuronal pathways responsible for the seizure In focusing attention on the complexity of the problem Dr Crome's paper has been very helpful.

CIVIL SERVICE MEDICAL APPOINTMENTS

SIR,—It was with the gravest disquietude that I read the recent advertisements in *The Lancet* to recruit doctors to posts within the Civil Service

Perhaps the most glaring anomaly in these advertisements is the statement that there are "promotion prospects," this statement appearing with surprising regularity in every post that is offered This would indeed be a welcome change of heart if it were so, but when the Treasury evidence to the Royal Commission in relation to the claims of the Civil Service doctors is studied the statement becomes ludicrous

Perhaps the intending applicant has not yet studied this evidence, which indicates fairly forcibly the poor opinion the Treasury holds of us doctors in the Civil Service, and they are the people who count when the question of numbers and remuneration of higher posts is under consideration

The additional information given to candidates with the application forms is no more informative regarding these "promotion prospects" A small paragraph states quite simply that certain grades exist, but it does not mention what we all know—that all these posts are filled and any promotion is unlikely in the foreseeable future

It appears to me that this should be made known to intending applicants, for the impression given by the advertisements is far removed from the situation as we know it

TOAD BENEATH THE HARROW

A LIVER POISON WITH UNUSUAL PROPERTIES

SIR,—I have read with interest the letter on icterogenin by Professor Rimington in your issue of April 9, and I am sorry that I did not know of his isolation of the lippia poison when I wrote my first letter I am glad to hear that studies of the icterogenic properties of this remarkable substance are already planned May I suggest some points which I feel are of special importance in further studies with icterogenin ?

Firstly, it seems to me important to decide whether icterogenin jaundice be a retention jaundice or a lymphogenous jaundice The poison may act in one of two ways (or perhaps in both of them) (1) by paralysing the bile-pigment excretion through the parenchymal liver cells, and (2) by reversing the secretion of these cells from the normal pathway (blood to bile capillaries) to an abnormal pathway (blood to lymph capillaries) [1 2a]

This may be decided experimentally by collecting the liver lymph (or thoracic duct lymph) during icterogenin poisoning and determining the concentration of bile pigment at different times and comparing it with that in the serum If the possibility (1) is correct a prompt direct diazo reaction in the serum (which is found in lippia poisoning) occurs without the bilirubin having passed the liver cells, and if (2) is correct the existence of a secondary secretory mechanism as pathogenesis of lymphogenous jaundice is proved [1 2a]

If (1) is correct our concepts of retention jaundice must be altered Up to the present our knowledge of experimental retention jaundice has been gained exclusively from studies on partial and complete removal of the liver—a technique which is far from ideal because the removal of the liver is followed by important changes in many vital functions and especially because bile pigment production in the stellate cells of Kupffer, which seems to form the bulk of the bile pigment in higher animals,[2b] is abolished

In this respect it is important to remember that the jaundice of acute yellow atrophy of the liver is accompanied by prompt direct diazo reaction [2c] In this condition all parenchymal liver cells must be considered necrotic or at least completely inactive, while the stellate cells of the liver are relatively unimpaired [2d], so the jaundice in acute yellow atrophy seems to come close to a pure retention jaundice, and thus to be very similar to icterogenin jaundice if possibility (1) is correct As the two conditions have the prompt direct diazo reaction (van den Bergh) in common, (1) cannot be excluded beforehand

If possibility (1) be correct our theory of jaundice must be altered because, according to current concepts, retention jaundice can only become intense after several days [2e], and this cannot be so if lippia jaundice is a pure retention jaundice, because it reaches high intensity in two to three days Perhaps the high bilirubin levels in occlusive and parenchymal jaundice may be explained by retention without regurgitation or other forms of lymphogenous return of bile pigments to the blood.

Secondly, studies in as many species as possible including both laboratory and farm animals and birds, and, if feasible, volunteers, are highly desirable

County Hospital,

ENURESIS

SIR,—This correspondence and a sentence in your leading article of Feb 19 ("We are not so well equipped to treat enuresis that we can ignore any promising technique") prompts me to write of some conclusions I have formed from twenty years of dealing, in the main successfully, with enuresis in children

Does not the cause of our lack of success lie in the tendency for the specialist to treat enuresis as a phenomenon of the urinary system alone, and for the general practitioner to take the opposite line and tell the mother that the child needs no help and will "grow out of it" ?

It is, of course, true, as you state, that in a certain proportion of children the situation arises from specific pathological conditions of the urinary system, but these cases amount to a very small proportion of those suffering from this very common complaint Elaborate urinary investigations, on the other hand, tend directly to increase the child's difficulties in gaining control, and to hinder the achievement of understanding by physician, mother, and child of the part played by delayed bladder control in any individual child

Surely the kernel of the whole problem lies in the power of the body to use its normal functions both to side-track and express emotional strains ?

Do we not all remember the frequency of our visits to the w c while waiting for *viva voce* examinations, and have we not noticed how the frequency and timing of micturition in ourselves varies with the weather and the emotional significance of the day's programme ?

This ability of the bladder to respond to factors affecting the whole personality is much more marked in children than in adults There is, also, an aspect of urinary performance additional to the emotional factors described by other correspondents, which is peculiar to children

The adult is used to himself and his physical apparatus he has, alas, in most instances, long ceased to "play," and his excreting organs are only of passing interest to him On the other hand, in children, curiosity, the desire to experiment, the enjoyment of "play," and the urge to acquire knowledge of himself and his functions, and of the mysterious lacks in his small sisters, leads to a concentration of interest on his excreting organ which can be overlaid with other activities during the day, but returns with full force when they vanish in sleep Then, the child who is disturbed in his personality, as described by Dr Symonds (Feb 26) and who has insufficient opportunity and/or ability to make friends" with the varied aspects of himself, and to gain release from tension in play, will use his urinary function to achieve this end in sleep

It is not the bladder or its controlling mechanism but the ole child who needs investigation and help

The difficulty in the treatment of enuresis arises from the paration between pædiatrics and child psychiatry so at the pædiatrician too often sees only the function and e psychiatrist only the personality and such common nse factors as maturation opportunities for play and nsible education of the mother in understanding both des of her child's nature so often do not appear at all

It has been our custom in our treatment at the Institute Child Psychology to provide a ground floor room with cement floor sloping to the outside with illumination from waterproof ship side lantern which is fitted with sinks at ifferent heights, water toys of all sorts and pots and jars nd hose-pipes. Here clothed in wellingtons and mackintosh child can work out in real water the drives fantasies and xperiments and—with the aid of the therapist—clarify he puzzles which lurk in his mind and perhaps tip the balance owards expression of all these through his own water reserves t night

As Dr Jackson (April 16 p 822) has so wisely pointed out rate of maturation varies enormously in different children (though surely he is incorrect in putting the lower limit for bladder control at three years ?) and giving up the desire for elementary water play is a function of maturation.

Institute of Child Psychology,
London W 11

MARGARET LOWENFELD

THE DIFFICULT APPENDIX

SIR,—Mr Kerr ends his interesting article of April 9 with the sentence I have regarded McBurney's point as $^1/_2$ in. below the midpoint of the line joining the umbilicus to the right anterior superior iliac spine.

This implies that there is some choice as to where McBurney's point may be placed This is not true as is shown by the following quotation from McBurney's original paper[1]

> And I believe that in every case the seat of greatest pain *determined by the pressure of one finger* [italics by the author] has been very exactly between an inch and a half and two inches from the anterior spinous process of the ilium on a straight line drawn from that process to the umbilicus. This may appear to be an affectation of accuracy but, so far as my experience goes the observation is correct.

An asterisk after this sentence points to a footnote which reads as follows :

> "Since reading this paper I have carefully observed three other cases. In two the point of pain shown by pressure with one finger was two inches and in the other an inch and seven-eighths from the anterior spine

George Washington University
Medical School Washington D C.

ALEC HORWITZ

CHRONIC SYSTEMIC LUPUS ERYTHEMATOSUS

SIR,—Your valuable leading article of April 16 prompts me to report 2 cases I have seen recently

A woman of 45 was admitted to hospital in November 1953 with pneumonia. She had had four attacks and a rheumatoid arthritis during the previous six years. She was found to have bilateral basal bronchopneumonia a rheumatoid form of arthritis, enlarged glands in the right axilla and sclerodermia of the hands Hb was 48% The serum albumin/globulin ratio was reversed and L.E cells were found in the blood smear Pyrexia persisted for weeks despite treatment with antibiotics. There was an immediate remarkable response to corticotrophin. Pyrexia ceased and expectoration of sputum stopped with astonishing rapidity This patient was discharged on 50 mg. of cortisone daily but later the kidneys were involved with albuminuria and uræmia and she died about a year after discharge

A man of 49 was admitted to hospital in June 1954 following five to six weeks of diarrhœa, with blood and mucus in the stools, and painful swelling of both legs Similar attacks of diarrhœa and pain and swelling in the legs had occurred at intervals for the past five years. He had had many attacks of episcleritis in the previous ten years. He had low fever episcleritis in the left eye cellulitis of the left leg and an anal fissure A barium enema showed appearances typical of ulcerative colitis Hb was 75%. Serum proteins were within normal limits. L.E. cells were found in the blood-smear Treatment with corticotrophin was started a month after admission. The pyrexia ceased within a few days and the diarrhœa stopped with astonishing rapidity The anal fissure healed shortly thereafter This man is out and about on 50 mg cortisone daily

These 2 cases represent a chronic form of systemic lupus erythematosus which appears to be commoner than its acute manifestations[1] Both presented without superficial skin lesions or albuminuria The clue to diagnosis in such cases seems to be recognition of the association of recurrent febrile illnesses such as pneumonia pleurisy, pericarditis conjunctivitis colitis &c with involvement of other systems notably the joints and lymph glands. Examination of the blood for L.E cells may be unexpectedly helpful

North Middlesex Hospital
London N 18

D FERRIMAN

CORPORAL PUNISHMENT IN SCHOOL

SIR—The question of corporal punishment in school and the principle underlying it should be decided on the rational ground whether it is favourable or not to the health of children in general As I see it this is a crucial and pressing issue not perhaps especially for doctors but for any society seriously concerned with the health of its children Perhaps therefore you will allow me to make some points on this question

The parent who nags his child to "concentrate who censures him for incontinence or thrashes him for pilfering is in the same boat with the teacher who cuffs his pupil for not attending to the board or for adding 2 and 3 to make 11 They are behaving exactly like the mechanist philosopher who by tradition has explained learning in terms of the law of use and the pain pleasure principle The former was based on the idea that repeated stimulation of a sensory nerve facilitated a muscle response the latter that pain inhibited and pleasure facilitated a muscle response

In the last half century the *Gestalt* scientists have produced an overwhelming mass of evidence against a mechanistic explanation of natural processes. They have established that the behaviour of living organisms is governed by the laws of organisation and they use the word insightful" to characterise the behaviour of all conscious organisms. Let anyone reflect whether a child has ever learned to be generous to control his bladder to solve a problem in mathematics to use crayon, brush, or tool through pain or fear or insightless drill In fact all these abilities are functions of the maturation and differentiation of the brain muscle gland organisation and the insight that depends on them.

That physiological processes like the maintenance of the acid base balance and of the constancy of the internal temperature are organised processes, justifies Cannon's use of the phrase the wisdom of the body Cannon has further shown that when an animal is affected by *any* painful situation it mobilises its energy for muscle action designed to relieve the stress and restore the animal's balance and unity Pain is thus not a deterrent but a positive incitor to action on the part of an organised being like an animal or child It is stress demanding resolution in action.

I consider that sexual tension grows out of" emotional tension in general and it is therefore easy to understand the two way traffic between sexual and any other kind of emotional tension I have known a child in whom masochistic behaviour had been evoked in infancy flee from punishment in school as from mortal danger and I have seen a hysterical reaction provoked in a teen-age girl at the mere witnessing of the punishment of other children. Any mode of education which uses punishment as a tool establishes a sado masochistic relationship between child and parent on the one hand and pupil and teacher on the other which will colour the child's whole life

But further the unremitting punitive tensions in home and in school to which children are subjected in certain areas are in my opinion a decisive factor in the production of serious physical illness. If, as I believe resistance is a condition of energy of the child as a whole then punishment will render him susceptible to illness by lowering his resistance

---

[1] McBurney C A) med J 1889 50 676

---

[1] Tumulty P A J Amer med Ass 1954 156 947

The analysts maintain that the child can "adapt" by using the punitive tensions of authority to build up his super ego and other internal forces of resistance He will then become a "good" person But he will externalise his "unconscious sense of guilt" and many such individuals are always "looking for something to forbid" and cannot even observe the natural behaviour of children without experiencing an inner compulsion to lay hands on them It is not surprising that analysis is confronted with the paradoxical situation of having to restore to broken lives the unity that they possessed in the beginning

Finally, what moral argument is there on behalf of punishment or the "threat of the withdrawal of love" as an instrument of education? As Kenneth Walker says in his *Sex and Society* "It is a betrayal of every spiritual value we profess to hold in reverence, to use love as a bait or a weapon of coercion"

Perranporth, Cornwall

A VISIT TO KOLTUSHI

Sir,—I found the article by Mr Ruscoe Clarke and Dr Leonard Crome (April 2) most interesting Of interest, too, were the comments of last week of Dr Mungo Douglas in that they represent a distaste for Pavlov's work which is by no means unusual in the British profession

However, one cannot but contrast the meticulous objectivity of the Pavlov school with the doctrinaire disregard of facts shown by Dr Mungo Douglas Instead of criticising the experimental findings, quoted by Mr Clarke and Dr Crome, he asks the rhetorical question "Is it a study likely to provide the kind of future we should all desire ?"

If it can be shown that the great mass of data accumulated by the Pavlov school is all wrong, or if it can be shown that these facts are without relevance to, for example, gastric function, bronchospasm, or, as suggested by Pavlov, schizophrenia, then it is open to Dr Mungo Douglas to prove his case But, in the scientific world at least, generalisations about vital freedom and enslavement cannot be accepted as a substitute for the dispassionate consideration of established facts

Personally I welcome all facts relating to conditioned reflexes since they touch on some very fundamental problems and suggest some interesting possibilities in clinical application

Sheffield C H Foggitt

PSORIASIS SPONDYLITICA

Sir,—Dr Lydon (April 30) asks us to support the unitarian theory of the pathogenesis of the rheumatic diseases This concept has, however, in the past, proved unhelpful in furthering our understanding of these disorders of connective tissue Moreover, as Professor Kellgren has pointed out,[1] just as no sensible person would seriously suggest that all diseases of the nervous system have a single ætiological factor, so it is equally unlikely in the case of the diseases of the supporting structures It is probable that research into the fundamental cause or causes of the rheumatic diseases will be easier once a greater knowledge of the normal anatomy and physiology of connective tissue and of the various clinicopathological entities which we call the rheumatic diseases has been acquired

As the expression of a useful piece of clinical observation, I, for one welcome the term "psoriasis spondylitica" used by Dr Fletcher and Dr Rose (April 2)

One other point arises from Dr Lydon's letter he is incorrect in regarding the arthritis of Reiter's disease as indistinguishable from rheumatoid arthritis—it differs from it in the joint "pattern" and in its course Reiter's arthritis predominantly affects the joints of the lower limbs, especially the knees and the ankles, it is also much more benign, and seldom leaves any permanent crippling deformities except in the feet

London W 1 J F Buchan

NON-PROGRESSIVE BREAST CANCERS

Sir,—Further evidence of the common occurrence of non-progressive, non lethal lesions, in general indistinguishable microscopically from lethal breast cancer, appears to be requisite for a fuller realisation or acceptance of the limitations of treatment Such evidence is obvious, I think, in the data of two series of cases cited previously[1] and other related data In one series, stage 1 (i e, confined to breast) constituted 50%, the 5 year survival-rate in the whole series was over 60%, and in the stage 1 cases it was 85 6% In the other series the respective figures were 16%, 43%, and 81% Consideration of all factors left no reasonable alternative to the deduction that the majority of stage 1 cancers in the first series were non-progressive lesions, and that they accounted, though not necessarily exclusively, for the unusually high 5 year survival rate for the whole series and largely accounted for the high 85 6% rate in the stage 1 cases The near equality of 85 6% and 81%, and the similarity of both with the rates usually obtained in stage-1 cases, point to similarity in the material providing these rates In other words, as the majority of the stage 1 forming 50% in the one series appeared to be non progressive lesions, it seems a reasonable deduction from the similarity of the survival-rates that the majority of stage-1 cancers in most series are similarly non progressive lesions The high proportion of non progressive lesions in the stage-1 cases could then explain, reasonably and consistently, the high survival rates in the latter In contrast to the contention that stage 1 lesions are progressive lethal cancers in an early and curable stage of development, this explanation is fully compatible with the persistence of level trends in age specific mortality in spite of an increase in stage 1 in the treated cases, compatible, too, with the wide variations in reported survival-rates in different series, and with frequencies of stage 1 and of grade 1 as found at different durations.

This does not imply that all the difficulties of differentiation are confined to stage 1 cases The wide difference in survival time even in well advanced cancer, both untreated and treated, reflects wide difference in the degree of malignancy in such cases That difference is not fully revealed even with grading of tumours by microscopy Lewison, in the Halsted Clinic, carefully re-examined sections from the tumours of patients who had survived ten years or more but found nothing on which to prognosticate the long survival[2] Morley et al found approximately the same five and ten year survival rates in *cases clinically stage 1 but pathologically* stage 2 (axillary involvement) as in cases clinically stage 1 but pathologically stage 1 The rates lay between those in stage 1 and those in stage 2 (clinically and pathologically) While the near equality of the survival rates in the two groups could be due to chance, it may indicate a degree of distribution of malignancy somewhat representative of such cases as those described An unidentified increase in such *clinically stage 1 but pathologically stage 2* cases in series treated in successive quinquennial periods *could thus* be a factor in the progressive increase in survival rates in the cases with *axillary involvement as reported* by several clinics[3]

As Smithers et al. have emphasised[4] survival rates are influenced by factors other than diagnosis and differentiation, such as difference in selection of cases after diagnosis, in staging criteria and their application, in detection of lymphatic involvement, in follow up, in calculation of survival rates, &c. However, when, in fifteen series of *different* time or place and for which the necessary data were available, the 5 year survivals of stage 1 were deducted from the over all 5-year survivals, the net 5 year survival rates then ranged from about 10% to about 30%, with the majority close to 20% They thus approximated to what might be found in untreated

4 *Brit J Radiol* 1952, suppl no 4

lethal cancers. This suggests that the content of non progressive lesions, as stage-1 cancers, is the most potent factor distorting survival rates and suggests also that the varying inclusion of such lesions accounts for most of the difference between survival rates of untreated and treated cases as well as between the rates of treated cases

These points are fully consistent with evidence previously reviewed, fully compatible, too with the findings of Murley et al. that all different treatments gave the same survival rates,[3] and also with the findings of Small and Dutton that some patients with treated breast cancer die at normal rates and others die at increased rates that "mortality in cancers is a constant process, little affected by treatment" and that 'it is doubtful if many more persons are cured by radical mastectomy than by other forms of treatment.'[5] The deductions or suggestions here really go little beyond what is already well recognised and is implicit in all the efforts that are being made to find a sounder basis for prognosis than microscopy provides.

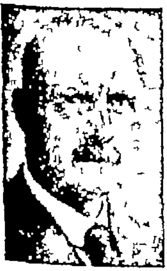
Obituary

HUGH ALLAN MACEWEN
O B E. M.B Glasg D.P H. F R.S.E.

Dr Hugh Macewen a former senior medical officer of the Ministry of Health, died at his home at Innellan, Argyllshire, on April 17

He was a son of Sir William Macewen professor of surgery in Glasgow University He entered the same university and graduated M.B in 1905 He early decided to specialise in public health, taking the D P H of Cambridge and of the London conjoint board in the following year He gained experience as assistant M.O H of Cumberland and M.O H of Fife and Kinross, and later visited the United States, where he was lecturer on hygiene at Cooper Medical College, San Francisco To this period belong his excellent manual on *Food Inspection* his account of *The Public Milk Supply* and his investigations into conveyance of whooping-cough from man to animals by direct experiment



Elliott & Fry

When Macewen was appointed a medical inspector of the Local Government Board Sir Arthur Newsholme then the medical officer of the board lost no time in employing him in important investigations He worked at first in the foods branch and then chiefly directed his attention to epidemiology His *Report on the Prevalence of Poliomyelitis in Certain Districts of Lancashire and Westmorland* (1914) confirmed the views of Wickman Reece, and others that the disease was spread by contact infection

During the first world war Macewen acted as one of the liaison officers between the War Office and the board in the inspection of military camps and hospitals in England and Wales and he was appointed O B E for his services. He became a medical officer of the Ministry of Health in 1919 From then onwards he was chiefly employed in medical administrative work at headquarters. His immediate chief was Colonel R J Reece the epidemiologist, for whom he had a warm friendship Macewen's abilities soon marked him out for promotion and a few years after the establishment of the Ministry he became senior medical officer of the branch of sanitary administration in relation to infectious disease With the passing of the Local Government Act in 1929 the Ministry became concerned with the new municipal hospitals and their efficiency and Macewen was appointed the senior medical officer of the branch which dealt with public health surveys, hospitals, and public-assistance medical services. This work he directed with his usual thoroughness and success. He was in charge of the special investigation into maternal mortality which was published as a white-paper by the Ministry of Health in 1937 In this inquiry his wife, Dr Barbara Cunningham O B E., took an important share. In the early years of the second world war he was in charge of the regional medical organisation, and it was once said that even the evacuation scheme for expectant mothers could not remove the smile from his face

In 1941 Macewen retired from the Ministry but not from medical practice He became medical superintendent of Ballochmyle Hospital in Ayrshire and acted for a time as M.O H of Ulverston rural and urban district in North Lancashire

As a senior medical officer at the Ministry in the 'twenties and thirties he came into close contact with the medical officers of the large local authorities and as the years went by he came to be more and more trusted by them. Many became his personal friends and one of them, W M F, writes 'Macewen showed his devotion to the cause of public health in everything he undertook. Despite the clinical atmosphere in which he was brought up, as the son of Sir William Macewen, he was convinced of the supreme importance of preventive medicine Before he began his long and successful career at the Local Government Board and at the Ministry of Health he was a medical officer of health and after his retirement, he became—temporarily—a medical officer of health again. To him and his colleagues at the Ministry we owe the rapid development of the personal health and hospital services during the twenty-one years between the first and second world wars. He possessed to an unusual degree the characteristic of selflessness Though he rose to a senior position at the Ministry, it was impossible to detect in him any signs of overweening ambition. Incapable of jealousy for himself he was jealous of the reputation of the English public health service'

A. S MacN writes Hugh Macewen was a man whose life and work were dominated by high ideals, and his sense of duty and devotion to the public weal never wavered He was serious in disposition except on social occasions when he would unbend and reveal a sense of humour He retained his Scottish accent was outspoken in his beliefs and while just and considerate to his medical officers, demanded and obtained the best from them Much of his valuable work for the Local Government Board and the Ministry of Health is to be found in official files reports and blue-books, and in all he did he worthily maintained the high standards and traditions of the central health department"

A colleague at the Ministry of Health writes Around 1930 a number of medical officers entering the Ministry were lucky in having Hugh Macewen for their chief and mentor The formidable exterior soon revealed beneath it a real kindness, a devotion to duty and a passion for accuracy which would never tolerate slapdash work. Verify your references—in the widest sense—might have been his watchword The department lost something of the old traditions and standards of the Local Government Board when he left, though he was able to do excellent work in Scotland both during and after the war He finished a fine life beside his beloved Clyde

HORACE BRYDEN HILL
M.B. Lond M R.C.P

Dr Horace Hill, medical superintendent of Laverstock House Salisbury who died on April 25 at the age of 76 was a man of considerable versatility

After qualifying from St Bartholomew's Hospital in 1901 he held house-appointments at Barts and at Huntingdon County Hospital In 1907 he took the M B Lond., and about this time he joined the Royal Navy and became a member of the staff of the Royal Naval Hospital at Haslar He had always been an all round athlete: an international hockey player and a member of the United Services cricket XI he also took a keen interest in boxing and played water polo This background led to his appointment to the staff of the Naval school for physical training at Portsmouth and

---

5 J Amer med Ass 1955 157 216

later he became instructor in physical training at the Royal Naval College, Osborne In 1911 he took the M R C P

During the 1914–18 war he served as a medical officer in H M S *Highflyer* He was made knight in the Order of St John of Jerusalem for his reorganisation of the training and service conditions of the Royal Naval Auxiliary Sick Berth Staff Reserve He also collaborated with Naval officers in an investigation of the best method of applying discipline in the Royal Navy He was made a chevalier of the Order of the Crown of Italy for his work in the Messina earthquake

After the war he left the Navy and settled in practice in Harley Street, joining the staff of the Royal Chest Hospital, City Road He was a vice-president of the Medical Defence Union In 1930 he published a handbook for students on *Electrocardiography* In 1936 he became medical superintendent at Laverstock House His later publications reflected his responsibilities and interests in this new appointment In his brochure in the *Public Attitude towards Mental Disease* (1939) he pointed out how desirable it was that relatives should not delay in seeking early treatment for a patient He also published a useful little book on safeguards in certifying those of unsound mind, and a more formal treatise on *Histamine and Insulin Treatment of Schizophrenia* (1940)

He was no mean painter, and some of his paintings hang in the Royal Fowey Yacht Club where he used to spend much of his leisure His widow survives him

DAVID WINN HOODLESS

O B E, B Sc Lond, L M S S A

WHEN Dr Hoodless was appointed the first principal of the Central Medical School in Fiji in 1929, he was already known, loved, and respected in the Pacific, for he had spent almost twenty years in the Colony as a schoolmaster and later as its director of education

Though his father was an engineer Hoodless came of farming stock He was born in 1887 in a small village in Nottinghamshire, and was educated at Sheffield and at King's College, London, where he gained a gold medal for mathematics, graduating B SC with honours in 1910 His first post as a teacher was in the training ship H M S *Worcester*, where he specialised in mathematics and navigation Two years later he went to Fiji as headmaster of a school for native boys, and later of the Queen Victoria School at Suva Through his work he came into close contact with the Fijian people, and his wish to serve them turned his thoughts to medicine In 1919 he came to England for two years to study at Charing Cross Hospital In 1921 he returned to the Pacific as inspector of schools in Fiji, and the following year he was appointed director of education During the five years that he held this post he established five new provincial schools to serve the Indian as well as the Fijian communities and started a scheme for recruiting teachers from New Zealand Such was his determination that he returned to England in 1928 to continue his medical studies, but illness prevented him from taking his finals in 1929 Despite his lack of formal medical qualifications he was wisely appointed the first principal of the Central Medical School When he qualified in 1935 he also took the diploma of tropical medicine

Hoodless did his task in Fiji so well that he was sent to inspect medical schools in Africa, but when the war broke out in 1939 he was recalled as he was indispensable to the Fijian government On his retirement in 1947 he was appointed O B.E He was an associate of King's College In 1953 he became correspondent to *The Times* in Fiji

P M-B writes "The name of Hoodless was one to conjure with in the Pacific He probably did more for medicine and education in Fiji than almost any other man He was the moving force behind the Central Medical School for Polynesians in Suva, and it must have been a great satisfaction to him when two years ago the Queen opened the fine hostel for Polynesians and the ancillary teaching blocks at the school An even greater satisfaction to him was the renown which the graduates of his school won from so many quarters during the late war Many of the Allies, mostly the Americans, were amazed at the knowledge and efficiency shown on many a lonely Pacific atoll by the Polynesian doctors who had been educated in Suva It was the greatest compliment to him that the American government for the island of Guam and the New Guinea government sent their quota of medical students to Suva Throughout the myriad islands of the Pacific he will be mourned as the guide, philosopher, and friend of the Polynesians, for he not only taught but guided and advised them as the ideal leader of their youth "

Dr Hoodless married in 1923 Miss Hilda Adlington, and there is a daughter of the marriage He was on holiday in this country with his wife when he was taken ill at Cambridge He died on April 15

Dr EGBERT MORLAND

S T writes Egbert Morland was a connoisseur of " obits " Not for him the list of dates and appointments culled from the reference books Every obit must stand on its own merits To write dully about the dull was a sin against the craft of journalism The ethic of happy curiosity, which he professed, made him certain that no life could be so barren as to yield nothing of interest, and it was the thing of interest alone which was worth recording But a good obit must not only interest, it must entertain, amuse, or edify It must tell the truth without unduly offending the relatives It must please friends and pacify enemies It must follow no logical pattern, but must blend fact and interpretation into a whole, having an artistic integrity of its own And if, on reading it, our eyes are filled with that divine mixture of laughter and tears, then it may be said to have succeeded

Egbert's attitude to obits followed from his rational Christian view of death Dying might be very unpleasant, but death was a brief moment of transition only and the gateway to another " awfully big adventure " He saw no reason to doubt the spiritual validity of Christ's promised immortality So when those we know or love come to die, selfish sorrow at our loss should deliberately be replaced by joy at their good fortune For Egbert, the conventional condolences and the trappings of mortality were a source of endless delight and amusement

I think Egbert was a Benthamite, a pragmatic utilitarian, to whom happiness was very important indeed. He wanted everybody to be happy, and saw no reason why he should not begin with himself

Despite an occasional witticism at the expense of reformers, he was a reformer himself. He was seeking ever to make the world happier, wiser, and more amusing. He was not always sure of the precise course to follow, but he turned this multivalence to positive advantage He would back people rather than plans Having picked his men or women, he would test them and try them with every devious tortuosity he could devise If they still came up smiling, or at least came up, he would give them their head At times, indeed, his trust was almost alarming So we of his staff were able to become once again " those sharp *Lancet* fellows " who had fought the good fight a hundred years before

Arrogance as a cloak for ignorance he would not tolerate Indeed the puncture of pomposity was a favourite occupation There was no subject on which he was ashamed to confess that he did not know, and he expected a like humility in others He had no patience with the establishment of a committee as an excuse for inaction and his gentle ruthlessness was often an unpleasant surprise to the " No " men of his day

It would be incorrect to say that the truth was not in him But sometimes it took a lot of finding " Always remember," he told me, " that in journalism interest is more important than accuracy " He held the view that the only purpose of writing was to be read If this failed, then the whole thing became a sterile intellectual exercise For the same reason, he loved the stimulating or provocative headline, the carminative which tempted the lazy appetite into operation The right place for the purely descriptive heading was the abstracting journal

Egbert's insight into his tortuosity was complete " Whether I have continued to edit *The Lancet* or become an inmate of Brixton has rested upon a knife-edge A single tiny genetic alteration and the coin might have come down the other way I hope I am enough of a knave not to be a fool "

As the years rolled by, his obliquities became more blique and the knight s moves of his mind took on an ver more fanciful pattern "I cannot solve your roblems, my dear fellow at best, and even this is nprobable, I may perhaps enable you to solve them r yourself' We were talking under a mighty tree in n Aylesbury garden and I left him with none of my onflicts resolved Yet over the months they melted way as perhaps he intended they should. Years before, hen I had been tortured by doubts he had joyously ut me on the right road when he finally saw he saw ith great clarity

Dear Egbert to have worked for you and with ou was a joy which time dims not at all To skip and icnic again with you and Mary in the Elysian Fields eyond the Chilterns robs death of its last remaining ting

E M C writes Your obituary notice of Dr Morland gives a vivid picture of his many sidedness I knew him or many years, but he still had a few surprises up his leeve and of course lots for the unwary who thought him merely eccentric or affected We once had the great joy of a holiday shared with him his wife and amily, and several young relatives. Led by him, the younger end of the party set off over the Gross Glockner pass to spend the night in the hut and go on to see the sunrise By then we were well acclimatised to the sun but I had had little experience of summer sun off the snow and by the evening my face was a mess with sunburn Next day after one look at it, Egbert said quietly, You and I are going to walk home by the valley, and leave the young ones to go over the top This was a great disappointment, but I couldn t question his judgment for I knew he was right. What I did not know was what a treat was in store, for his knowledge of Alpines was encyclopædic. I shall never forget that walk, taking it easy and stopping to look at first one and then the next little masterpiece, held out for me to see or just lifted up from the edge of the snow He felt a little guilty not to have warned me about the sun the day before, but, characteristically, it was the plants with which he was tender

Notes and News

HEALTH CENTRES AT YORK AND STRANRAER

WITHIN the past month two new health centres have been opened—at York and Stranraer

Performing the ceremony at York on April 14, Sir John Charles, chief medical officer of the Ministry of Health, declared that there was nothing so inspiring, so apt to promote smooth and efficient performance, as the outward and visible signs of bricks and mortar—such a sign as the new centre The centre is in the middle of a large post war housing estate and it will serve a population of about 25,000 In the first place, it will provide maternity and child welfare, health visiting, school nursing, and dental services, but the building has been designed in such a way that an extra wing of consulting rooms for general practitioners can readily be added later Alternatively, general practitioners may rent some of the existing accommodation, and discussions on this question are in hand The centre has been planned so that different kinds of patients are in independent units but they can all be easily supervised from the central administration offices The cost of the present building was £13,000

Stranraer's health centre is the second to be newly built in Scotland (the other is at Sighthill in Edinburgh [1]), and the first to be built adjoining or connected to an existing hospital It contains five consulting suites for the general practitioners of Stranraer, who have a total of 13,200 people on their N.H S lists In another wing there are three rooms and a dental workshop for local authority services, and the local authority will share another four rooms with the board of management responsible for the adjoining Garrick Hospital In addition the hospital has for its own use a changing room, a plaster room, and rooms for an X-ray unit The cost was about £33,000, of which the hospital authority will contribute some £12,000 The centre was opened on May 6 by Mr H R Smith, secretary of the Department of Health for Scotland

University of Oxford

On April 28 the following degrees were conferred

D M—Zelda M Hall Constance L Simpson
D Sc—W Ritchie Russell

University of Glasgow

On April 30 the following degrees were conferred

M D—M C Macleod (honours), R C MacLeod.
Ph D—T C D Whiteside

Royal College of Physicians of Edinburgh

At a meeting of the College held on May 3, with Sir Stanley Davidson, the president, in the chair, the following were elected to the membership

J M Johnston H R Harris T M Desai L Molk M. B Azami R H Aldons S K Mazumdar, D O Lewis, D A Kerfoot E N A Magid, J Richmond, E Schiller W G Smith S S Levin E S Nash J R. Shah B C Syam I J Pinto R C Parikh N H Brooke S C Jain, B Cowan, R. H C Rischbieth W H Wolfenden J C Pond M Wakefield, G D Campbell, B C Paton, M A Kibel

Hunterian Society

Mr A Dickson Wright has been elected president of this society for 1955–56

Royal Society of Tropical Medicine and Hygiene

The Chalmers medal for 1955 has been awarded to Dr W E Kershaw, lecturer in medical parasitology, Liverpool School of Tropical Medicine

N A P T Travelling Fellowship

The Scottish branch of the National Association for the Prevention of Tuberculosis offers a travelling fellowship (£250), for postgraduate study abroad, to a doctor working in Scotland on tuberculosis Applications should be sent not later than July 15 to the Scottish secretary, N A P T, 65, Castle Street, Edinburgh, 2

British Society for Research in Ageing

This society will hold a symposium on Thursday, June 9, at 2 P.M, at 41, Portland Place, London, W 1, on Endocrinology and Ageing Prof G R Cameron, F R S, will be in the chair The speakers will include V Korenchevsky (London), J A Loraine (Edinburgh), P L Krohn (Birmingham), and P J Thung, L Boot, and O Mühlbock (Amsterdam) Further information may be had from the hon secretary, Mr G H. Bourne D.SC, London Hospital Medical College, Turner Street, E 1

Sydney Body Medal

This medal has been awarded to Dr L Gordon Hopkins "for his unsurpassed services to medicine during fifty years in Southend."

Medical Records Exhibition

This exhibition will be held at the Bonnington Hotel, Southampton Row, London, W C 1, from 10 A.M to 6 P.M on Saturday, May 21 At 11 A M Dr N M Goodman will give a lecture on Statistics and Records of Cancer The exhibition has been organised by the Association of Medical Records Officers to help hospital staffs to deal with problems of indexing, correspondence, outpatient waiting, admission and discharge procedure, and storage of records

International Society for Human and Animal Mycology

Last year, at the 8th International Congress of Botany, this society was founded to bring together those interested in the study of fungi living on humans and animals The president is P Redaelli (Milan) and one of the vice-presidents is G T Ainsworth (Exeter) Further particulars may be had from Prof R Vanbreuseghem, Institute of Tropical Medicine, 155, rue Nationale, Antwerp, Belgium.

Hospital for Tuberculosis in Malaya

Dr M R J Snelling, chest physician at the King Edward VII Sanatorium, Midhurst, has been appointed the first medical superintendent to the Lady Templer Hospital for Tuberculosis at Kuala Lumpur This new hospital, which has 250 beds, is to be run on similar lines to those of the King Edward VII Sanatorium. A thoracic surgeon and a team are shortly to join Dr Snelling, and Australia is sending 28 nursing sisters

French Prize for Medical Film

At the fourth distribution by the *Presse Médicale* of prizes for medical films the prize for the best foreign entry was awarded to C E Engel (London) for his film on *Mitral valvulotomy for mitral stenosis* Honourable mention was given to the film by P Hansell (London) on *Grafting on the cornea* Applications for next year's competition will be received up to the end of next February, addressed to the *Presse Médicale*, 120 Boulevard Saint Germain, Paris VI

Nursing Times

The golden jubilee of the *Nursing Times* was marked by a luncheon in London on May 6, under the chairmanship of Mr Daniel Macmillan Sir Harold Boldero recalled that only in the past half-century had nursing become fully established as a profession landmarks in this period included the foundation of the College of Nursing in 1916, the Registration Act of 1919, and the adoption by the college of the *Nursing Times* as its official journal in 1926 He went on to refer with regret to the fragmentation of medicine, and wondered whether the same sort of thing was happening in nursing Did those engaged in teaching nursing—who seemed to spend all their time on this task—go into the wards and see what was being done there? Did district nurses go into the hospitals? The medical curriculum was admittedly overloaded, and he asked whether the nursing curriculum was similarly overloaded or (which came to the same thing) there was insufficient time in which to teach everything included in the curriculum. Miss M. L Wenger, editor of the *Nursing Times*, spoke of some of that journal's activities Recently these had included the encouragement of recruitment to the mental hospitals and the offer of a bursary to enable a nurse to spend a year in the study of journalism, for they believed that nurses should be able to describe the results of their work. Dame Enid Russell Smith enunciated five aims for a professional journal First, it should advance professional knowledge (of course in language understandable to no layman) secondly, it should present professional political issues without bias, bitterness, or personalities, thirdly, it should put the work and aims of the profession in the setting of the fuller scheme of things (the margin between proper professional pride and arrogance was narrow), fourthly, it should set a high standard of professional ethics and support the best traditions (thus acting as the profession's memory); and fifthly, it should encourage the pioneering spirit, so that no reader, after studying any issue of the journal, could feel any self satisfaction at all The *Nursing Times* had succeeded in each of these aims Finally Miss S C Bovill spoke with pleasure of the association between the Royal College of Nursing, of which she is president, and the *Nursing Times*

A draft British standard for gas-cylinder trolleys has been issued by the British Standards Institution Comments should be sent to the institution 2, Park Street London W 1, before June 7

THE CLINICIAN AND
E PROBLEM OF MULTIPLE SCLEROSIS*

Douglas McAlpine
M.D Glasg F R C P

ICIAN IN CHARGE OF DEPARTMENT FOR NERVOUS DISEASES, DLESEX HOSPITAL, LONDON PHYSICIAN MAIDA VALE HOSPITAL FOR NERVOUS DISEASES

DURING the past quarter of a century there has been a able revival of interest in multiple or disseminated rosis particularly in America In the laboratory the erimental pathologist has evolved a technique by ich an encephalomyelitis can be produced in animals luding the monkey by means of subcutaneous or amuscular injections of brain tissue along with an uvant consisting of heat killed tubercle bacilli. The ults of these experiments have suggested to some ervers that brain tissue may contain a chemical agent ich acts as an antigen producing antibodies that react h constituents of white matter The part played by adjuvant used in these experiments is uncertain

Meanwhile, clinicians have contributed mainly in two ections—first in geographical and racial studies and ondly in attempts to determine more accurately the ure of the disease.

Geographical surveys were undertaken first in Switzer d by Bing and Reese (1926) and subsequently in nmark (Gram 1934) Sweden (Sällström 1942), and ts of the United States of America (Kurland 1952) st of these surveys have suffered from one serious ect—namely that the results have been based either death certificates or on information obtained from eral practitioners. Notable exceptions have been those ently carried out by Allison and Millar (1954) in thern Ireland and by Dr John Sutherland in Northern tland

Allison and Millar personally examined all cases orted to them by general practitioners over a three ar period After discarding 187 cases 700 remained in ich they were satisfied that the diagnosis was either bable or possible Using the census figures of 1951 y were able to arrive at a prevalence rate of 7 0 per 000 after excluding persons under the age of 20 By ermining the geographical distribution by place of et, Allison and Millar found that the disease in rthern Ireland does not affect rural populations more n urban nor did they find any evidence to suggest a al incidence

Dr Sutherland has recently completed a survey of the ease in the Orkney and Shetland Isles the Western es and the mainland counties of Caithness Sutherland ss and Cromarty Inverness, and Nairn I am grateful him for permission to refer to certain of his findings questionnaire was sent to all general practitioners in se regions asking for the names and addresses of all pected cases of multiple sclerosis; replies were received m 93% of practitioners 180 cases were notified of ich 16 were rejected 10 other patients had either ed after the case had been notified or had removed from region these 10 cases were discarded Of the maining cases 127 were classified as probable and as 'possible cases of multiple sclerosis On the is of the 1951 census figures Dr Sutherland found an er-all prevalence rate of 5 5 per 10 000; if possible ses were included the figure rose to 6 7 In the Shetland es the relative figures were 11 3 and 12 0 per 10 000 e highest rate yet recorded in Great Britain

In the Northern Ireland and Northern Scotland rveys a significant familial incidence was found to hich I shall refer later

The results of these surveys justify the hope that similar field studies of multiple sclerosis in Great Britain will be encouraged, particularly in areas with a reputedly high prevalence rate

Other contributions made by clinicians in recent years include studies of the course of the disease and its prognosis In the past estimates of its duration were usually based on fatal cases. A notable exception was Byrom Bramwell's (1917) follow up of a series of cases over a period of twenty years However, the main credit for introducing some order into this subject must go to Ragnar Müller (1949) whose conclusions are of particular value because of the size of his material and his application of the statistical method His results and those of other workers including Allison (1950) have shown that the outlook for the patient with multiple sclerosis is considerably better than was formerly supposed

These outstanding contributions must not blind us to the fact that other aspects of the natural history of the disease as well as its symptomatology have been largely neglected in recent years My primary purpose here is to indicate the further value of these two lines of study

Aspects of the Natural History

The Familial Incidence

Preoccupation with the hereditary forms of cerebellar and paraplegic disorder may be the main reason for the long delay in the recognition of a small but significant familial incidence in this disease It was the appearance of Curtius's paper in 1933 that stimulated interest in this subject. He found a familial incidence in 6 4% of 106 cases observed in Bonn and Heidelberg (Curtius 1933 Curtius and Speer 1937) Since no case of multiple sclerosis was detected in a control population he concluded that the incidence of secondary cases in the families of multiple sclerosis patients was considerably raised when compared with a control population Since 8 positive family histories were obtained in a series of 142 cases reported from the Middlesex Hospital in 1946 an additional series was investigated with Pratt and Compston (1951) In a total of 310 cases the familial incidence was 6·5% In the Northern Ireland survey the figure was 6 58% Millar and Allison were the first to compare the expected risk in siblings of patients with multiple sclerosis with the rate in a control population studied in the same area and at the same time They estimated the risk to be about ten times greater in siblings of patients than in the control population and agreed with our view that the excess risk is not due to a common environment or to infection but to a genetically determined predisposition In the Northern Scotland survey there were 12 families with more than one case of multiple sclerosis an incidence of 9·4% This figure errs on the conservative side since in 12 other families there was a positive history but as the diagnosis could not be satisfactorily established in the secondary cases they were excluded Dr Sutherland rejected a diagnosis of multiple sclerosis in three brothers living in the Island of Lewis affected by a progressive spastic paraplegia preferring to regard it as a purely hereditary condition In the Orkney and Shetland Isles the familial incidence exceeded 10% Parental consanguinity seemed a possible explanation for this high figure but the incidence proved to be comparatively low Dr Sutherland's observations which cover racial dietetic and other factors may throw further light on the relative parts played by heredity and environment in this disease

Precipitating and Aggravating Factors

At the end of the last century and the beginning of the present one there are many references in the literature especially German to the effect of such factors as infection injury physical exertion exposure to damp and cold emotional upset, and prolonged worry in unmasking

The Florence Tong lecture delivered before the Association of British Neurologists at Cambridge on March 25 1955

6378

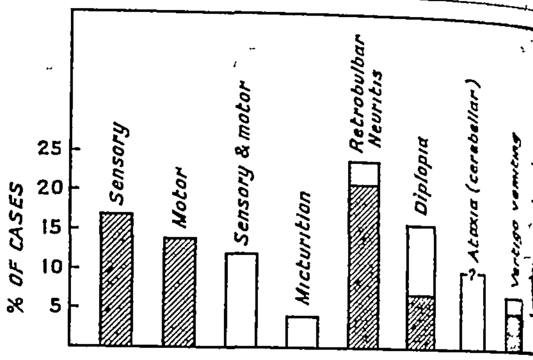
the first symptoms of the disease In 1934 Hoesslin published a monograph devoted to these so called exogenous factors

The criteria necessary to establish a causal relationship between a supposed precipitating factor and the onset of the first symptom of multiple sclerosis or a relapse are (1) a temporal relationship, and (2) a significant incidence of the factor in comparison with a control series The time interval is difficult to fix, and a period of three months which we arbitrarily chose in studying these factors seemed reasonable (McAlpine and Compston 1952) However, if it could be shown that a causal relationship may exist between trauma, for example, and the onset of the disease, it would be necessary to visualise a longer time-interval than three months Turning to the second point, the evidence in the literature is of little value judged by present day statistical standards Bearing this fact in mind I propose to discuss briefly four conditions which appear with sufficient frequency in the immediate past history of these patients as to warrant attention

General health —It is by no means exceptional to find that for days or weeks before the appearance of the first symptoms, or accompanying them, the patient has not felt in his or her usual health, has lacked energy, has tired easily, and in addition may have noticed headache and vague pains in the back or limbs On inquiry these somewhat indefinite symptoms may have coincided with a period of overwork or overstrain, but in other patients no adequate cause can be found Although by no means the rule, these premonitory symptoms deserve further study, since if we understood their meaning they might provide a partial clue to the ætiology of the disease

Infection —This usually takes the form of a cold, a sore throat, or influenza Bramwell obtained the high figure of 14% of infections preceding the onset in 200 cases, and Hoesslin 10 5% in 109 acute cases, which is approximately the figure obtained by Compston and myself in 250 consecutive cases Taking these figures and those in other series into account, it may be said that 10% represents the approximate incidence of some form of infection before the onset. If attention be paid to this question it will be found that not infrequently in an established case of the disease, a relapse may immediately follow an upper respiratory infection

Trauma —The third factor is trauma, whose occasional relationship to the onset of multiple sclerosis has been commented upon by numerous writers (McAlpine and Compston 1952) In our own series of 250 consecutive cases particular care was taken to exclude trauma from a fall due to the disease In the three months preceding the onset there was a history of trauma, including dental extractions but not surgical operations, in 36 patients (14%) as compared with a similar history in 13 patients (5 2%) in a control series of hospital inpatients With regard to the site and degree of trauma, it has been assumed by most writers that the injury must be cranial or spinal and severe in degree (Keschner 1950) Whether the changes set up in the nervous system are primarily vascular or chemical, there seems no reason to exclude the limbs when considering the site of trauma Hoesslin was the first to suggest that there may be a relationship between the site of the trauma and that of the first symptom Of our series of 250 cases, in 22 out of 36 (61%) patients who gave a history of trauma, there appeared to be a correlation between the site of the injury and the part of the body, usually a limb, in which the first symptom appeared We also showed that the relapse rate within the three months following trauma, whether this was accidental or surgical, was significantly greater than the expected relapse-rate during the same period This evidence, of which fuller details are given in our paper, suggests that slight or severe trauma, including an operative procedure, to a limb or any part of the body, may occasionally precipitate the disease or may be the cause of a relapse



Initial symptoms of multiple sclerosis, occuring alone (hatched columns) or in combination, in 309 cases.

Allergic disorders —The incidence of allergic disorders in the past history of patients will naturally depend on the scope of the inquiry In our series we found no significant difference in the remote past history of multiple sclerosis patients as compared with a control group , but in the three months preceding the onset of the disease, and in the subsequent months or years, such a history was obtained in approximately 9%, as compared with an average of 2 8% in a control series.

If mental stress be added to the factors which I have mentioned—namely, a lowered state of general health, trauma, infection, and an accompanying allergic disorder —it may be estimated that one at least of these occurs in a close time relationship to the onset in roughly every other patient, an estimate which probably errs on the conservative side

Features of the Early Symptomatology

There is still no consensus of opinion as to the relative incidence of the initial symptoms It therefore seems worth analysing the notes of the 309 cases finally diagnosed as multiple sclerosis after admission to the Department for Nervous Diseases, the Middlesex Hospital, under myself and my colleague Dr Michael Kremer, over a five year period from January, 1950, to December, 1954 Doubtful cases were excluded By limiting the analysis to inpatients admitted to the same department it was hoped that some degree of uniformity in history taking, methods of investigation, and final diagnosis would be achieved

In constructing the accompanying figure, motor and sensory symptoms associated with brain stem signs have been omitted , so the columns marked " motor " and " sensory " refer to cases in which there was a high probability of one or more plaques in the spinal cord Symptoms rarely met with at the onset, such as an isolated facial palsy, have also been excluded

This analysis emphasises the frequency of a monosymptomatic type of onset, which was seen in nearly two thirds of the cases in this series An isolated retrobulbar neuritis may be expected as the first sign in about one patient in every five , parresthesiæ in one out of every six , and thereafter, in diminishing order of frequency, motor weakness (usually in a lower limb), double vision, vertigo, and vomiting

One of the characteristic and at the same time puzzling features of multiple sclerosis is the extreme variability in the mode of onset and duration of the first symptom At one end of the scale is the so-called apoplectiform onset recognised by Charcot , at the other end is the slow insidious appearance of a paraplegia due to spinal plaques How to explain these two modes of onset on the basis of a common pathological process is one of the many unanswered questions relating to this disease Tr oints, however, should be borne in mind: first the age ncidence differs, an abrupt onset being more common in ounger patients while the slowly progressive form of ne disease mainly occurs in those over the age of 40 nd secondly as in certain other diseases—notably heumatoid arthritis—the individual's reaction to the orbid process can apparently determine the tempo of ne initial symptoms and the subsequent course

ransitory Episodes and Exacerbations

The adjectives "transitory' fleeting or short ved" are often used by writers in describing early ymptoms. The vagueness of these terms leaves the verage reader in some doubt as to their meaning hough he may gain an impression that they indicate a eriod of one or more days. Accordingly serious attention seldom given to attacks of blurred vision double vision iddiness, or pins and needles in a limb lasting a few ours or even minutes. Yet such episodes are not ncommon in the past history of patients presenting ith undoubted signs of the disease

The factors determining the onset of these fleeting arly symptoms deserve further study So far as my own mited observations go, it seems that, in the main they re similar to those that may provoke more lasting ymptoms I have been struck by the fact that a patient resenting with well marked sensory disturbance in a and, may for several weeks previously have noticed emporary tingling and perhaps numbness in the fingers f the same hand on awaking from sleep or sometimes fter using the hand Likewise an attack of retrobulbar euritis may be preceded by episodes of blurred vision rought on by exertion or emotion The following case s illustrative

Mrs. A aged 23 a hairdresser when playing tennis one ay in September 1953 noticed hazy vision with difficulty in eing the ball She stopped playing and after a short rest er vision became normal. Subsequently whenever she layed tennis or danced vision was temporarily blurred. In ay 1954, she began cycling to work a distance of about a ile By the time she arrived vision was so poor that she was nable to start work until she had rested for a short time oon afterwards she also noticed numbness in the right hand r some hours after cutting several customers hair in ccession.

In June 1954, vision was 6/5 both eyes, the fundi were ormal and no scotoma could be demonstrated (Mr A J B oldsmith) By July she found that even mild exertion, such s walking quickly affected her eyes to an increasing extent nd soon vision became permanently blurred By October ision was 6/60 in both eyes both discs were pale and a small ilateral central scotoma was now present

On admission in December vision had not improved and he now showed nystagmus and bilateral extensor plantar esponses. After cycling on a fixed bicycle vision became worse comparison of the scotoma in the right eye on an Amsler's hart before this exercise and after four minutes showed that t had markedly extended Five minutes later the central efect had returned to its previous size

To be distinguished, at least clinically from these ransitory initial episodes are the temporary exacerbations of symptoms which may be a sequel to an established plaque. Of 250 cases investigated by Compston and myself 82 (32%) gave a history of temporary worsening of symptoms during stress, a finding confirmed y Pratt (1951) An emotional upset may act rapidly n motor function, paræsthesiæ and vision Likewise xertion may have the same effect. These temporary hanges are of course seen in other organic conditions of he nervous system such as traumatic paraplegia but t is our impression that they occur more easily and are nduced by a larger range of exciting factors in multiple clerosis than in other organic conditions

Franklin and Brickner (1947) suggested that these hanges are due to vasospasm for they observed localized constriction of retinal arteries during episodes of blurred vision An increased vulnerability of the axis cylinder to chemical influences offers an alternative explanation

Symptom and Lesion

At first glance any attempt to correlate disturbance of function and of structure in multiple sclerosis may seem profitless However not infrequently the earliest symptoms are caused by a focal disturbance, thus permitting a clinical study of their mode of evolution I have in mind particularly sensory symptoms due to invasion of the spinal cord As Oppenheim (1911) originally pointed out tingling and numbness are usually caused by one or more plaques in the posterior columns Furthermore since the cervical cord is often attacked early in the disease a special opportunity is afforded the clinician of studying sensory symptoms since at that level afferent impulses from all four limbs and the trunk are represented in a known anatomical relationship to each other within a small area (McAlpine 1954)

Although tingling and numbness may be confined to a small area on a limb or the trunk not uncommonly they tend to spread by noting the original site of the paræsthesiæ and direction of spread it becomes evident that this is often determined by the anatomical arrangement of the proprioceptive fibres within the posterior columns. For example a spread of numbness from a hand to the shoulder and then down the homolateral trunk and finally to the lower limb is indicative of a focus in the column of Bordach extending inwards to the column of Goll. Similarly a spread may take place in the reverse direction Thus the mode of spread appears to be determined by contiguity of structure

Another feature which can be recognised clinically is the symmetry sometimes shown by plaques. For example it is not uncommon for paræsthesiæ to affect simultaneously or in quick succession corresponding parts of the lower or upper limbs, and be followed by a similar mode of spread in the four limbs A further example of symmetry is provided by retrobulbar neuritis which, contrary to many statements may affect both eyes simultaneously in multiple sclerosis This symmetrical tendency of plaques, which many years ago was commented on by pathologists poses yet another question for which at present there is no satisfactory answer

Multiple Sclerosis or Spondylosis

So far I have considered certain features of the relapsing and remitting form of the disease Presenting a striking contrast in its mode of onset and its course is the so-called progressive paraplegic or spinal form of multiple sclerosis which chiefly affects the middle-aged

In the analysis of the 309 cases already referred to I came across 27 with signs of a spastic paraplegia in which the diagnosis of multiple sclerosis was at first in doubt During the same period 31 cases of spinal cord compression due to tumour (excluding secondary deposits) came under the care of Miss Diana Beck Dr M Kremer or myself In recent years myelography has substantially reduced the number of cases of cord compression mistaken for the spinal form of multiple sclerosis Today the neurologist, while constantly aware of this pitfall, must also take into account the possibility of cervical spondylosis when confronted with a paraplegia in middle age Over the five year period already referred to there were 30 such cases. An analysis of this group and that of the 27 patients with the spinal form of multiple sclerosis showed that, while the clinical picture in the two groups was broadly similar there were certain points of difference *First the average age of onset differed* in the multiple sclerosis group it was 42 and in the cervical spondylosis group 51, the youngest patient being 27 and the oldest 68 It is in the *fifth* decade of life however that the distinction between these two causes of paraplegia may be difficult A gradual onset and slow progression of motor weakness—first in one lower limb and then in the homolateral upper limb—without any sensory symptoms or signs, may occasionally occur in the progressive form of multiple sclerosis, none of our cases of myelopathy associated with cervical spondylosis showed this pseudohemiplegic type of progression In multiple sclerosis short attacks of tingling and numbness, usually brought on by exertion, may antedate motor weakness by weeks or months, but such a history is rarely obtained in cervical spondylosis The spread of paræsthesiæ, when it occurs in multiple sclerosis, tends to be much more rapid than in spondylosis Pain in the upper or lower limbs is a well recognised feature of the early phase of spondylosis, yet it was not a rare symptom in this small group of multiple sclerosis patients, being among the presenting symptoms in 8 of the 27 cases, it was usually referred to one or both lower limbs or the back Scattered references to pain in this disease can be found in the literature, and since its interpretation remains in doubt it is worthy of further study

A history of early disturbance of sphincter control was found more commonly in multiple sclerosis as compared with the myelopathy of spondylosis, the figures being 14 of the 27 multiple sclerosis cases compared with 8 of the 30 spondylosis patients An episode of temporary incontinence early in the history should suggest multiple sclerosis

The course of the spinal form of multiple sclerosis is sometimes interrupted by a superimposed relapse, this occurred in 3 cases in this series in the form of paræsthesiæ which developed over the course of a few days and then receded I have not met with similar episodes in the myelopathy of spondylosis

Regarding signs, the upper limb reflexes afford little help in differentiating between these two groups of patients—particularly depression or absence of one or more of these reflexes, since this occurred with almost equal frequency in the two groups While muscular wasting in the upper limb was relatively more common in the spondylosis group, 2 cases of tetraplegia due to multiple sclerosis showed wasting of the intrinsic muscles of the hands, a finding which was commented upon by Déjerine (1884) when he drew attention to the similarity between this form of the disease and amyotrophic lateral sclerosis

The presence of nystagmus proved to be the most helpful single diagnostic sign it was present in 14 of the multiple sclerosis cases, but in only 4 of those with spondylosis In these 4 patients it was purely horizontal in type and was associated with evidence of involvement of the upper cervical cord as judged by exaggeration of some of the upper limb reflexes or by radiological evidence of spondylosis as high as C3–4 In the multiple sclerosis group a well marked rotatory or monocular nystagmus was not unusual and provided evidence of an extraspinal lesion

Apart from nystagmus, evidence of one or more lesions above the level of the spinal cord was found in 9 of the multiple sclerosis cases, unilateral temporal pallor of the discs (4 cases), mild dysarthria (3 cases), and an exaggerated jaw-jerk (2 cases) Euphoria was noted in 2 patients but only in the course of a follow-up when symptoms had been present for several years

The findings in the cerebrospinal fluid proved of the utmost value, particularly in those cases in which signs were confined to the spinal cord 12 of the 27 multiple-sclerosis patients showed a marked paretic curve, in 6 others there was a mid-zone curve of at least 2's In 1 case the only abnormality was a rise in the protein figure, in the remaining 8 cases the fluid was normal on one or more occasions By contrast, a mid-zone curve of 2's was only found in 2 cases of cervical spondylosis, in the remaining 28 cases the Lange curve was normal

Before leaving these two groups of patients, I wish briefly to refer to 8 cases in the multiple sclerosis group which showed clear evidence of cervical spondylosis The youngest patient was 31 at the onset of symptoms and the oldest 51, with an average age of 42 The diagnosis of multiple sclerosis in these patients with cervical spondylosis was based on the points already mentioned, with the addition of myelography in two cases In 2 cases protein figures of 130 and 120 mg. per 100 ml were found

A woman, aged 44, had for two years received treatment for pain in the neck and left arm due to well marked cervical spondylosis Rather abruptly she began to stagger when walking and she was admitted under the care of my colleague Dr Kremer Among the positive signs were a pronounced monocular nystagmus, limb ataxia, a mild paraparesis, and a strongly paretic gold curve She responded only slightly to traction and some months later was readmitted with an abrupt progression of symptoms

The second case was a male, with onset of symptoms at the age of 31, who five years later was dysarthric and showed temporal pallor of one disc and nystagmus. There was no evidence of block on flexion and extension of the head during lumbar puncture

It is probable that in these two patients the spondylosis accounted in some degree for the high protein figure. A marked rise in protein occurs rarely in uncomplicated cases of multiple sclerosis For example, only 5 out of 512 spinal fluids from cases of multiple sclerosis examined by the Courtauld Institute at the Middlesex Hospital showed a figure of 100 mg, or more, per 100 ml

Conclusions

Certain of the facts mentioned in this lecture may be summarised as follows

First, of the chronic organic nervous diseases occurring in the British Isles, multiple sclerosis now appears to be the commonest The surveys of Northern Ireland and Northern Scotland show that in these parts of our islands at least one adult in every 1[illegible] is affected by it The figure for England and Wales is probably only a little behind this one.

Secondly, there is a small but significant familial incidence varying in Great Britain from 5% to just over 10% Since it is exceptional to find more than two members of a family, whatever its size, affected by the disease, it must be assumed that when present the genetic influence is usually weak and must be reinforced by constitutional or environmental factors before the nervous system is attacked, and furthermore, that the disease may develop in the absence of any obvious genetic influence

Thirdly, in some patients a variety of factors, including ill health, an infection, trauma, and emotional stress may precipitate not only the onset of the disease, but also relapses

The fourth fact about the disease concerns its abrupt onset and the natural tendency for symptoms to remit and later recur—features which for many years have been recognised as likely to provide a clue as to its ætiology

Lastly, the considerable variation in the behaviour of the disease in its earlier stages must depend on the individual's reaction to it

The Allergic Theory

For too long our attention has been fixed on the nervous system in multiple sclerosis Detailed though the average history may be regarding events relating to this system, account is seldom taken of the recent and past general medical history Yet it is in the medical background of these patients that we must look for the events which in a small proportion of the population initiate changes in the myelin sheath Of recent views as to the cause of the disease, the so called allergic theory is perhaps the one most acceptable to the clinician The occasional familial incidence, the nature and variety of the precipitating factors, the presence of some other form of allergy, before or after the onset, in a significant proportion of cases, an abnormal sensitivity to drug d lastly the abrupt onset and characteristic relapsing d remitting course—all these factors may be cited in pport of the view that multiple sclerosis represents a pe of immunity reaction in the central nervous system cAlpine and Compston 1952)

Since confirmation or otherwise of this hypothesis ay be long delayed perhaps it is permissible to consider e nature of the hypothetical sensitising agent or agents. general allergens are derived from bacteria from otein derivatives and from drugs Since the breakdown oducts of bacteria constitute their commonest source, appears likely that, if sensitisation plays any part in e genesis of multiple sclerosis, an infection initiates e process, at least in some patients However, in ractice it would be difficult to prove such a relationship -first because of the time lag that might theoretically ccur between the infection and the first clinical evidence f the disease (McAlpine 1946) and secondly because s Rich (1947) has pointed out in discussing the question f allergy once a tissue has become sensitised it may bsequently react to a wide range of substances Sup ort for the idea of a latent or asymptomatic phase of ultiple sclerosis comes from a consideration of the part layed by the so called precipitating factors. These are learly not strictly causal but in the words of Lumsden, 'either they fire off or trigger' an intrinsic self propa ating mechanism, or they provoke the onset of symptoms n connection with areas of the white matter already nvolved by the disease process' (McAlpine Compston nd Lumsden 1955) The second of these postulates eems probable and is consistent with the theory of llergy

ourse of the Disease

This leads me to consider briefly certain features of arly symptomatology and the light they may throw on he nature of the initial change in myelin sheath Tran itory and recurrent symptoms such as diplopia, blurred ision and paræsthesiæ, which in some patients may onstitute the earliest evidence of the disease, could be xplained on the basis of the so-called shadow plaque eferred to by Lumsden (1951) In this stage of partial emyelination it is not difficult to imagine that the nderlying axis cylinder might react abnormally to a ariety of stimuli If the concept of an initial asympto matic phase of the disease be accepted, does demyelination egin during this period or is there a stage of pre emyelination in which the complex cytochemical alance of the sheath is in some way altered?

In 1903 Williamson, of Manchester was struck by the imilarity between the pattern produced by the applica ion of a soluble dye to the cut surface of the spinal cord nd the mode of development of plaques In 1933 Hallervorden and Spatz drew attention to the occasional ccurrence of a ring formation in the early plaques of multiple sclerosis similar to that observed in Balo s oncentric sclerosis. They attributed this type of forma ion to diffusion outwards from a central focus as in the o-called *Laesegang* phenomenon a subject recently iscussed by Lumsden (McAlpine Compston and Lumsden 1955) The tendency for early symptoms articularly paræsthesiæ to spread according to contigu ity of structure lends support to the possible rôle of a rocess of diffusion

The next question concerns the important issue as o whether arrest of the disease is ever possible For the athologist this seems unlikely since plaques tend to volve slowly and progressively On the other hand the linician is aware of cases in which after one or more pisodes no fresh evidence of the disease is apparent for many years and even in some instances for the rest of the patient s life Unless there is a system for following up arly cases most of these patients will be missed for they may have no occasion to report either to their general ractitioner or to hospital From my own observations I am satisfied that the incidence of these mild cases with a good resistance to the disease is rather higher than is generally supposed

It may be possible to reconcile these differing view points of clinician and pathologist The manner in which early symptoms clear up and may remain in abeyance for several years emphasises the potential reversibility or at least non progression of the early lesion; by contrast we are well aware of the probable course when paraplegic or cerebellar signs become established It is in this type of case that we can understand the evolution of the plaque as seen in the post mortem room

Treatment

Lastly brief reference must be made to the present unsatisfactory attitude towards treatment This attitude is determined by two beliefs—first that a serious degree of disability is inevitable in all cases however treated and secondly that treatment consists solely in palliative measures I have already pointed out that the prognosis as a whole is less unfavourable than was formerly thought and in some patients the disease runs a relatively benign course As regards treatment, the lack of an effective remedy should not blind us to the necessity of adopting a more positive attitude towards these patients, particu larly in the early stage of the disease before irreversible changes in the nervous system have taken place Assum ing that constitutional factors are important in the ætiology of multiple sclerosis, then it is our duty first to ensure an adequate period of rest in bed after the onset or a relapse followed by a long period of convales cence and secondly, to increase as far as possible the patient s resistance to the disease by close attention to physical and mental health over the first few crucial years

Owing to its capricious behaviour the assessment of treatment in multiple sclerosis has always presented difficulties. Yet the necessity of devising a method of evaluating a particular remedy is obvious Compston (1953) has suggested a formula by which the relapse rate before and after treatment can be compared. This method however does not cover the effect on recent symptoms

After consultation with Dr Richard Doll a form of trial has been devised in which a control group of patients can be used Briefly the trial is divided into two parts. The first enables a comparison to be made of the effects of treatment during a month s stay in hospital in two groups of patients one on the drug under trial and the other on some form of recognised treatment such as arsenic The object of the second trial is to assess the effect of the drug on the relapse rate It is hoped that experience gained during the next year will show the value of these two forms of trial

I would like to conclude with two observations The natural history of multiple sclerosis suggests that it is not due to a single cause but to the interplay of a number of factors—genetic constitutional and environmental Despite its complexity we as neurologists should not be content to leave this problem to the laboratory worker but with widened outlook should endeavour to play a part in its solution

REPORTS from the United States and elsewhere indicate that hydrocortisone (17-hydroxycorticosterone, or compound F) ointment is highly effective in the treatment of various pruritic dermatoses

Sulzberger (1954) found it helpful in infantile eczema, atopic (pruriginous) dermatitis, contact eczematous dermatitis, otitis externa, nummular eczema, seborrhœic eczema, pruritus ani et vulvæ, exfoliative erythroderma of eczematoid or seborrhœic type, and some cases of eczematous and lichenified eruptions of the hands, feet, eyelids, face, neck, and genitalia, also in the "distinctive exudative, discoid, and lichenified dermatosis" of Sulzberger and Garbe Hydrocortisone has proved ineffective in pemphigus vulgaris, lichen planus, alopecia areata, psoriasis, and discoid lupus erythematosus, it does not inhibit the development of erythema from exposure to ultraviolet rays (Everall and Fisher 1952)

Alexander and Manheim (1953) and Malkinson and Wells (1954) have formed similar opinions, but they consider that hydrocortisone is ineffective in general exfoliative dermatitis, autosensitisation, and "-ide" (bacterial or fungous allergy) eruptions

McCorriston (1954), using hydrocortisone ointment in various vehicles, obtained 75–100% relief in 104 children and infants with eczema

Robinson (1953) obtained dramatic relief in 20 of 28 patients with atopic dermatitis, in 5 of 8 patients with pruritus vulvæ, and in 1 of 3 patients with pruritus ani 1 patient with discoid lupus erythematosus showed a good response and 2 showed fair responses

Sidi et al. (1953) state that the most striking effect is on pruritus, the action being immediate and lasting for at least twelve hours They used it for exogenous, allergic, seborrhœic, nummular, and purpuric eczemas, for pruritus, for chronic dermatitis of the eyelids, and for various other dermatoses

Goldman and Preston (1954) treated 22 cases of poison ivy dermatitis, with excellent results in 3, slight changes in 5, and no change in 14 cases

These reports suggest that hydrocortisone ointment relieves itching and reduces the manifestations of inflammation in a number of skin diseases, but in none of the above trials were concealed controls employed In the trial of any new treatment for pruritic conditions it is important to eliminate as far as possible the influence of suggestion, particularly when physical signs are slight and reliance has to be placed on subjective impressions

When anti histamine drugs were introduced, it was soon reported that they were effective local applications for the relief of itching Many of these claims were based on uncontrolled trials, on comparisons with previous remedies, or on trials which employed contralateral controls Later, Baldridge (1951) treated 41 patients with 5% phenindamine ('Thephorin') ointment on one side and its unmedicated base as a control on the other These were presented as "slightly different forms of the same medication" to the patients who were asked to estimate the percentage of relief on the two sides 47% of the areas treated with thephorin were reported as relieved, and 49% of the areas treated with the unmedicated base were reported as relieved Many dermatologists now agree that most anti histamine drugs are useless when applied topically

It can be said of contralateral controlled trials that at least four fallacies may invalidate the results

(1) Absorption may lead to remote as well as local effects

(2) The trial substance may inadvertently be transferred to the opposite side

(3) Unless the lesions on the two sides are of equal intensity and duration, they are not strictly comparable (e g, the response to treatment of an eczematide cannot be compared with that of the primary lesion—perhaps an area of unilateral hypostatic eczema—from which it developed) This difficulty can be overcome by random allocation of treatment and control to right and left sides, but even then, unless a large number of patients are included in the trial, the results may prove inconclusive

(4) There may be a *Mitreaktion* (Siemens 1951, 1953) in which, when a patch of skin disease is treated on one side of the body, untreated areas on the opposite side also show improvement This may be the result of a spinal reflex, or it may be accounted for by the reduction in the amount of circulating histamine which follows treatment.

The Present Trial

In assessing the value of hydrocortisone ointment ('Hydro Cortisyl,' Roussel), we used concealed, alternating, self contained controls, the patients themselves recorded their daily progress over fourteen consecutive days on cards supplied to them each week

CONTROL BY ALTERNATION

A trial in which (*a*) the vehicle alone and (*b*) the substance being tested are used alternately in treatment has much to commend it, provided certain criteria are observed, and certain uncontrollable factors are appreciated

1 The number of patients tested in each group must be sufficiently large

2 The patient should be unaware that an ointment containing a trial substance is being tested against the ointment alone

3 The clinician should not know when the patient receives the trial ointment and when he receives the vehicle alone until the specified period of the trial has been completed and all data have been recorded

4 It is possible that either substance will continue to exert some effect during the first few days after replacement by the other Thus the test remedy (or the vehicle alone) when applied during the second week may appear more (or less) effective than in the first week

5 The days of starting treatment should be evenly distributed through the week so as to spread the possible influence of weekends and bank holidays

6 The influence of menstruation is unlikely to be important if patients are introduced to the trial as they attend for treatment, without reference to the stage in the monthly cycle

7 If the whole trial covers several months, and preferably a year or more, and if patients enter it at various times, the influence of seasonal climatic changes is unlikely to be important

8 The influence of extraneous factors such as fatigue, emotional disturbances, &c, may affect individual results Such factors should be noted at each attendance

9 Any record keeping by the patient is an abnormal state of affairs In suggestible patients results may prove better than might be expected, in very conscientious patients over-attention to the skin may cause increased awareness of itching Both possibilities are likely, not only with the

vehicle but with the test substance as well. Reciprocal short-term trials are a useful means of determining the worth of a new remedy for chronic benign cutaneous reactions: the patient runs no risk and suffers no inconvenience if the vehicle is harmless; the vehicle may in fact prove helpful in itself.

THE RECORD CARDS

'Record of itching' cards, adapted from cards used by Hodgkinson (1954) for controlled clinical trials of analgesic drugs, were designed for the trial as follows:

RECORD OF ITCHING

Date

Patient's Name Record No

	Very good day (no itching)	Fair day (less itching)	Average day (usual itching)	Bad day (more itching)
Sun.				
Mon.				
Tue.				
Wed.				
Thu.				
Fri.				
Sat.				

Place X in appropriate space each morning for previous day

The patient's name and record number and the date were entered by the clinician, and a mark was made to show on which day of the week the trial began. The patient's attention was then drawn to the request at the foot of the card: "Place X in appropriate space each morning for previous day." The appropriate spaces recorded whether the patient had had a "very good day" (no itching), a "fair day" (less itching), an "average day" (usual itching), or a "bad day" (more itching).

The patients were unaware that two different preparations were being given to them. They were informed that it was desired to find the worth of a remedy and that for this purpose a trial lasting two weeks was necessary. No "salesmanship" was employed, and the use of superlatives or of such adjectives as "American" and "special" was avoided. On the contrary, a restrained remark such as the following was made: "Please apply the ointment very thinly twice a day and record its effects on this card." At the second attendance, no matter what the result of the first week's treatment had been, a comment was made such as the following: "A fortnight's treatment is needed to give the remedy a thorough trial. It is best to have a fresh supply. Please discard any ointment that remains and indicate results on this card for another week." All patients coöperated well and seemed to understand what was required of them. There were no 'spoiled papers'.

The method of prescribing was to write on the standard outpatient prescription card: "HC ung trial 1st (or 2nd) week 5 g, store no. 1." The patients were told that only a small quantity of ointment could be provided for one week's treatment, and they were sent to a special section of the outpatient dispensary. This enabled concealed records to be made and kept by one pharmacist, who was also responsible for arranging an approximately equal distribution between the A B (hydrocortisone→vehicle) and the B A (vehicle→hydrocortisone) trials. He did this by alternating the A B and the B A sequence. This resulted in a random distribution because there were eight different skin conditions included in the trial. There were 66 patients in the A B sequence and 63 in the B A, while 3 patients did not complete the trial. We four clinicians had no means of telling which patients received the A B and which the B A sequence, because we did not know when one of us had introduced a new patient to the trial—or for that matter the order in which the patients arrived at the dispensary. 5 g of ointment or base was dispensed as a rule, but sometimes 10 g was given. The control ointment (of propylene glycol, polyethylene glycols, and zinc stearate) was the same as the vehicle for the 2.5% hydrocortisone acetate ointment; the two ointments were identical in appearance. Identical plastic ointment boxes were used for the trial substance and for the base. They were not labelled in any way to indicate the nature of the contents. At the end of each fortnight's trial the pharmacist was asked to divulge the treatment that had been given each week, so that a decision might be made on the future treatment of that patient. Progress notes were also made at each attendance, the patient's verbal descriptions being recorded; these made a valuable parallel study to the record cards. Changes in physical signs were also recorded.

In some of the conditions—e.g., anogenital pruritus—physical signs were often slight or absent, the changes being mainly or entirely subjective. In patients with multiple lesions—e.g., some cases of discoid eczema—the trial ointments had to be applied to one area only, while the remaining lesions were treated with some other bland local application. As far as possible sedatives were withheld during the trial period; if they were necessary, they were given for both weeks in identical doses.

On inspecting both cards, and after allowing for carry-over effects, it was usually easy to decide which preparation was the more effective. The subjective results recorded during the last day or two of a week's trial were often poorer than during the middle of the week. We believe that this was often due to the necessity for very sparing use of the ointment towards the end of each week because of the small amount (5 g.) that was usually supplied.

In cases where the 2.5% hydrocortisone ointment proved more effective than the base alone, treatment was continued with 1% hydrocortisone ointment. Sometimes treatment was continued with the base and a change-over to 2.5% or 1% *hydrocortisone ointment* was made after a further week or two without the patient's knowledge. It was thus possible to clarify inconclusive impressions gained from the first trial. It was also possible to compare the efficacy of 2.5% with 1% hydrocortisone ointment; sometimes the 2.5% preparation was necessary for complete control, in others 1% was sufficient.

MATERIAL

Included in the trial were 132 patients (72 males and 60 females), with the following conditions:

25 with anogenital pruritus.
21 with lichen simplex.
12 with infantile eczema.
22 with Besnier's prurigo.
23 with discoid eczema.
11 with chronic idiopathic eczematous dermatitis of the hands.
11 with otitis externa.
7 with pruritic psoriasis, *mostly anogenital*.

RESULTS

Points were allotted daily to each patient studied, allowing 2 points for complete relief, 1 for partial relief, 0 for no change, and −1 for *worsening*. *These numerals* indicate trends only and in no way imply degrees or percentages of relief. The points scored are recorded on block diagrams in figs. 1–8. These show great individual variations of subjective relief. We have thought it valid to summarise the effects obtained in "hydrocortisone" and "vehicle" groups during the week of their application. The daily means are set out in table I.

The number of patients in a few of the groups was too small for dogmatic statements, but it is clear from this table that appreciably greater *improvement* sometimes resulted from the use of hydrocortisone. No absolute criterion of efficacy can be applied, but on the above rating the results may be summarised thus:

Lichen simplex, discoid eczema, and otitis externa.—The results were strongly in favour of hydrocortisone.

Infantile eczema and idiopathic eczematous dermatitis of the hands.—The results, though apparently in favour of hydrocortisone, were less conclusive.

Pruritic anogenital psoriasis.—The results were equivocal. In the course of treatment with hydrocortisone ointment 6 patients improved and 1 worsened, while with the vehicle alone 5 patients improved and 2 worsened. This suggests that the vehicle was responsible for the improvement.

Besnier's prurigo.—Slightly better results were obtained with the vehicle alone, but neither hydrocortisone nor the vehicle produced very good results. Undoubtedly the trial was often inadequate in this condition, because the cost and scarcity of hydrocortisone made it advisable to use it only on the worst, lichenified areas in these patients. Nevertheless, clinical and electro-encephalographic evidence (Ingram 1955, Russell and Last 1955) indicates that this disease affects the whole ectoderm (nervous system and skin), so it is not surprising that local treatment by itself should prove ineffective.

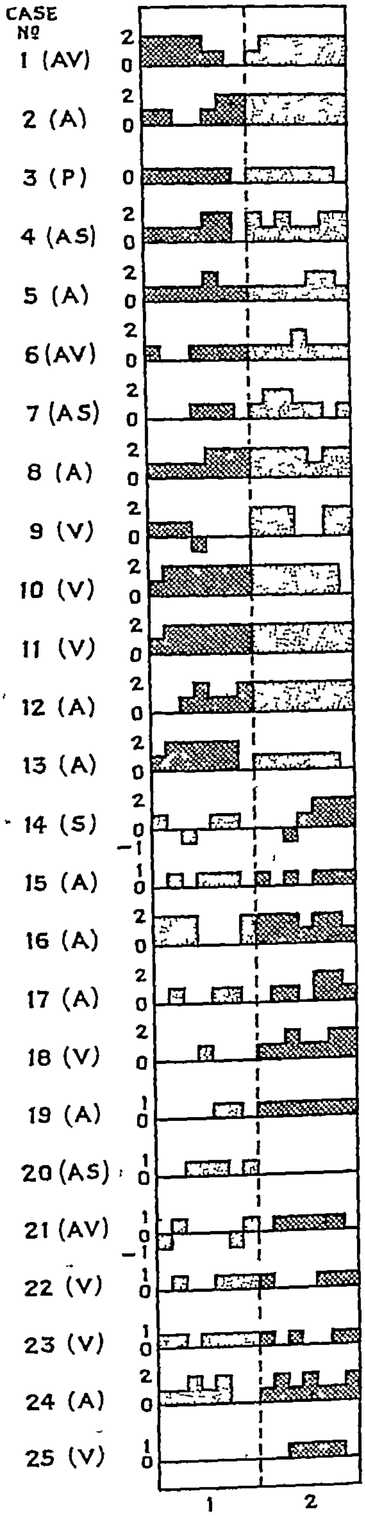

Fig 1—Results in 25 cases of anogenital pruritus.

A = anal P = perineal

S = scrotal V = vulvar

Anogenital pruritus.—Slightly better results were obtained with the vehicle alone. Nevertheless excellent longer-term results were obtained in this condition with hydrocortisone (see below), 32% of patients being completely relieved and another 24% much improved. We can only suggest that our equivocal findings in the "switch-over" trial were due to one or more of the following factors: the shortness of the trial, the undoubted efficacy of the vehicle itself, the carry-over effects from one week to the next, and, in some cases, the influence of suggestion. There was no obvious difference between the results obtained in anal pruritus and in genital pruritus. Patients with distinct physical signs—chiefly lichenification—responded best, and those without physical signs responded worst. This is not surprising, for pruritus without physical signs is probably of central origin.

SIDE-EFFECTS FROM HYDROCORTISONE OINTMENT

Remote Effects

We have seen no evidence of remote ill effects following the use of hydrocortisone ointment.

Smith (1953) found no significant change in the eosinophil count after the inunction of 6 g. of 2.5% hydrocortisone-acetate ointment, and he thought it unlikely that amounts of hydrocortisone so small as to escape detection could account for the therapeutic effects reported. No systemic ill effect has been reported from the prolonged application of hydrocortisone ointment.

Local Irritation, Sensitisation, and Aggravation of Infective Dermatoses

In the series of Malkinson and Wells (1954) irritation developed in 4 of 71 patients treated, and the treatment was stopped, but no case of sensitisation to hydrocortisone has yet been reported. There were no cases in our series. 3 of Robinson's (1953) patients complained of increased burning and itching when the ointment was applied, and 2 of them were found to be sensitive to the lanolin in the ointment base. The ointment used in the present trial did not contain lanolin. A few of our patients stated that it was "too drying," but the great majority found it comforting and aesthetically acceptable. The occasional complaint of undue dryness can be overcome by having an alternative vehicle of hydrous ointment type, but the routine use of a greasy vehicle of this sort would be liable to cause maceration of the skin at some sites.

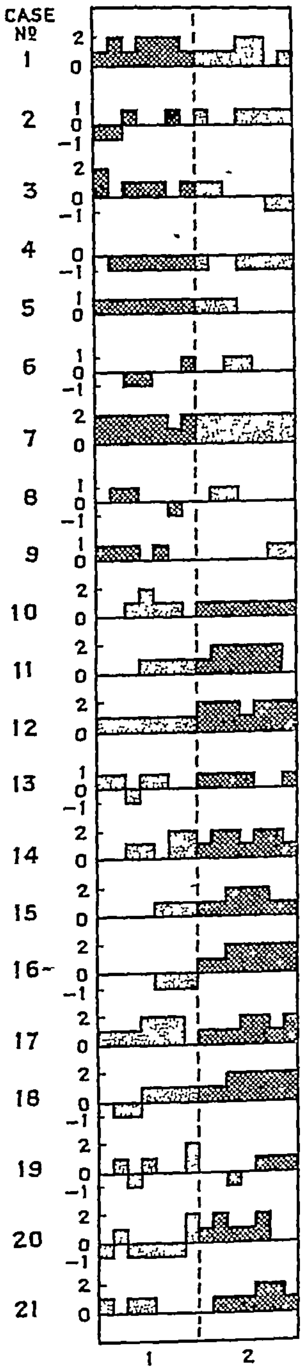

Fig 2—Results in 21 cases of lichen simplex.

3 of our patients abandoned the treatment and were not included in the tabulated results. They were:

1. A patient with discoid eczema who complained that the ointment "burned." She was receiving the vehicle alone at the time. She refused to attend again for patch testing, on the grounds that the dermatosis had cleared up with treatment for her "nerves."

2. A patient with chronic eczematous dermatitis of the hands, of unknown cause, who complained of fresh outcrops of vesicles after applying hydrocortisone ointment for three days. She abandoned its use. Patch tests with the hydrocortisone ointment and with the vehicle alone were negative, but when patch testing was carried out with the separate constitutents of the vehicle, a positive response was obtained to propylene glycol. Her dermatitis subsequently improved

---

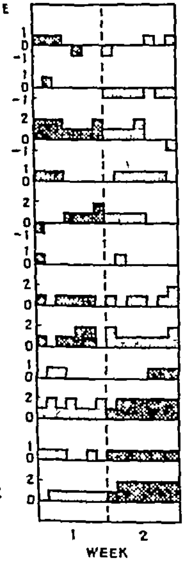
Hatched = hydrocortisone. Stippled = vehicle. 2 = no itching. 1 = diminished itching. 0 = usual itching. −1 = increasing itching.

ly when 2·5% hydrocortisone, with hydrous ointment as ehicle was applied. This had been specially prepared r request.

A patient with otitis externa, whose ears became more en and exudative shortly after he began treatment with ocortisone ointment. His eyes also became swollen. Cul revealed *Staphylococcus pyogenes*, *streptococcus hæmolyticus* *Pseudomonas pyocyanea*. Patch tests with hydrocortisone with the vehicle were negative.

alkinson and Wells (1954) did not find that secon ly infected dermatitis was aggravated by the drug.

The anti-inflammatory action of hydrocortisone relieves itching and lessens scratching, thus diminishing bacterial contamination of the lesions and bringing about amelioration of the infective as well as of the eczematous and lichenified elements. On the other hand, dermal infections with cocci (such as erysipelas, boils, and ecthyma) should in theory be aggravated by hydrocortisone, which has the effect of lowering the resistance of the host, thus enabling the organisms to multiply (Houghton 1954, Hart 1954). This matter is still sub judice.



3—Results in 12 cases of infantile eczema.

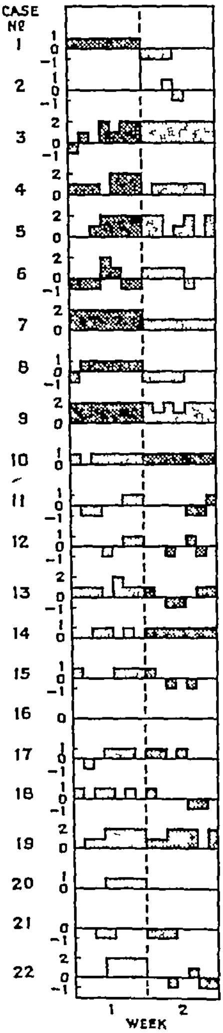


Fig 4—Results in 22 cases of Besnier's prurigo.

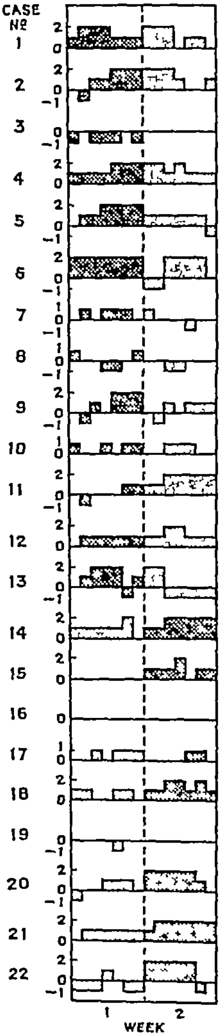

Fig 5—Results in 23 cases of discoid eczema. The 23rd patient failed to complete the trial.

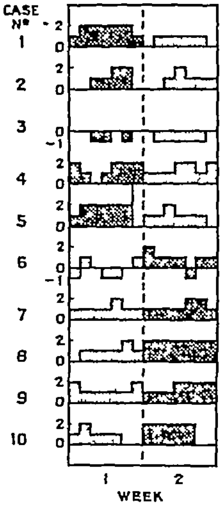

Fig 7—Results in 11 cases of otitis externa. The 11th patient failed to complete the trial.

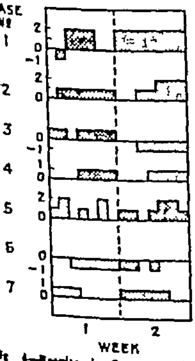

6—Results in 7 cases of pruritus of anogenital region.

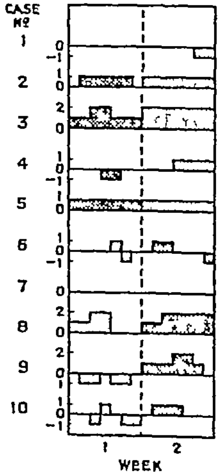

Fig 8—Results in 11 cases of eczematous dermatitis of hands. The 11th patient failed to complete the trial.

TABLE I—MEAN DAILY RESPONSE SCORES

Diagnosis	No of cases	Score with hydrocortisone	Score with vehicle
Anogenital pruritus	25	1 01	1 04
Lichen simplex	21	1 00	0 49
Infantile eczema	12	0 84	0 55
Besnier's prurigo	22	0 54	0 59
Discoid eczema	23	0 97	0 57
Idiopathic eczematous dermatitis of the hands	11	0 61	0 43
Otitis externa	11	1 28	0 79
Pruritic anogenital psoriasis	7	0 63	0 51

EFFICACY OF THE VEHICLE

In trials such as this it is always possible that the bland vehicle may have a considerable antipruritic action

Sulzberger and Witten (1952), in their early trials of hydrocortisone, noted some improvement with the ointment base alone, though less than with the ointment containing hydrocortisone McCorriston (1954), too, noted that in a number of patients the control sites of the soft paraffin and emulgent bases showed some improvement This was confirmed in a later study by Sulzberger et al (1953) Most of their patients were treated with hydrocortisone acetate in a non greasy base (containing zinc stearate, propylene glycol, polyethylene glycols, and water)

Robinson (1953) noted that after the condition had been controlled by hydrocortisone, it often seemed to respond better to other local therapy than previously

McCorriston has used hydrocortisone in four different vehicles in the treatment of infantile eczema These were a cream of zinc stearate, propylene glycol, polyethylene glycols, and water, white soft paraffin, a jelly base, and an oil in-water emulgent base Though the cream was useful in the weeping stage, the jelly was found to be too drying The soft paraffin or the emulgent base were preferable for dry, thick, scaly areas

In the present trial the vehicle was similar to that used by Sulzberger and Witten (1952)—namely, a non greasy polyethylene glycol base Polyethylene glycols (Smyth et al 1950) have proved less irritant than soft paraffin mild sensitisation reactions (faint erythema) as almost as common as with lanolin, soft paraffin, simple cerate, and simple ointment Case reports of sensitivity to polyethylene glycols are very few Strauss (1950) reported 2 cases of sensitivity to the entire group of polyethylene glycols These substances are non-ionic (Schutz 1953), they are therefore insensitive to metallic ions, and can be used both in acid and in alkaline media They dissolve or emulsify lipophilic substances and are valuable vehicles for oil soluble drugs when it is desired to bring these into close contact with the skin and with its folds

Results obtained with the vehicle in the present study indicate that it is remarkably effective by itself as an emollient and as an antipruritic agent, but its efficacy is far less than that of hydrocortisone ointment in of the skin diseases that we have studied

From the cosmetic point of view, a non greasy b of the "vanishing" type is more pleasant than a greasy ointment We agree with Sidi and Bourgeois Gavardin (1953) that the polyethylene-glycol base has an action superior to that of most local applications, and it has the advantages of being æsthetically acceptable and not necessitating dressings

TABLE II—INDEPENDENT ASSESSMENT OF EFFECT OF HYDROCORTISONE OINTMENT

Disorder	Cleared without relapse	Completely controlled	Much improved	Slightly improved	Unchanged	Worse or course abandoned
Anogenital pruritus	2	6	6	8	2	1
Lichen simplex	0	2	8	3	7	1
Infantile eczema	0	2	0	6	4	0
Besnier's prurigo	0	2	1	7	11	1
Discoid eczema	2	3	4	4	9	1
Idiopathic eczematous dermatitis of the hands	0	1	2	1	5	2
Otitis externa	2	3	2	2	1	1
Pruritic anogenital psoriasis	1	0	1	1	4	0
Total	7	19	24	32	43	7

SUBSEQUENT PROGRESS

With more prolonged treatment (without concealed control or record cards) progress has been maintained in lichen simplex, discoid eczema, anogenital pruritus, and otitis externa As extraneous events have a powerful influence on progress in infantile eczema, hydrocortisone ointment, though often helpful, may have to be assisted by sedative drugs In cases of Besnier's prurigo we have not felt justified in continuing treatment with hydrocortisone

INDEPENDENT ASSESSMENT

An independent observer (Dr C M Ridley) has perused the case notes and analysed the results. The assessment (table II) was made on subjective impressions combined with the objective evidence recorded in the notes, it attempted to measure the effect from the beginning to the end of treatment with hydrocortisone ointment The duration of treatment varied from two weeks to several weeks In some cases treatment with hydrocortisone ointment was still in progress at the time of the assessment

CONTACT ECZEMATOUS DERMATITIS

We have observed marked relief of contact eczematous dermatitis with hydrocortisone ointment However, the condition does not lend itself to controlled studies, its natural course differing greatly from one person to another

Summary

Concealed trials with hydrocortisone ointment, alternated with its vehicle alone, and a longer term independent survey of results, have shown that hydrocortisone was remarkably effective in many patients with lichen simplex, discoid eczema, otitis externa, and anogenital pruritus In infantile eczema and in idiopathic eczematous dermatitis of the hands the improvement was less obvious In Besnier's prurigo local improvement was sometimes obtained, but the general results were poor one reason for this may have been that the ointment applied in very small quantities In itchy psoriasis of the anogenital region the results apparently depended on the efficacy of the vehicle

Hydrocortisone ointment is also highly effective in contact eczematous dermatitis, but examples of condition have not been included in these controlled

An independent observer, assessing the results, cluded that there had been distinct or complete relief in 14 of 25 patients with anogenital pruritus, in 10 of with lichen simplex, in 2 of 12 with infantile eczema, in 3 of 22 with Besnier's prurigo, in 9 of 23 with discoid eczema, in 3 of 11 with idiopathic eczematous dermatitis of the hands, in 7 of 11 with otitis externa, and of 7 with itchy flexural and genital psoriasis

Only 1 of the 132 patients in the trial proved sensitive to the vehicle, but relief was subsequently obtained with hydrocortisone in hydrous ointment 1 patient complained that the ointment caused a burning sensation in another infection increased during treatment

We wish to thank Dr L Bernstein, of the department of physiology of the London Hospital, for his statistical guidance and constructive criticism, and Dr A E Gremeaux, of Roussel Laboratories, for his coöperation, and for supplying the hydrocortisone ointment and the inert vehicle which we sed in the trial We also thank Mr D C Phillips of the harmaceutical department of the London Hospital, who ersonally supervised the concealed trial

Cholera, a disease characterised by loss of fluid lowered blood volume shock and anoxia appears to be an ideal condition for the study of Selye s (1950) alarm reaction in man However very little is known about the activity of the suprarenal glands in cholera

Rogers (1921) citing Nearne considered the high tolerance of cholera patients to adrenaline as an indication of suprarenal dysfunction.

Chatterjee (1930) studied the suprarenal glands from some cases of cholera and thought the congestion of boundary zone to be related to the extreme shock of the first stage of the disease

Lahiri (1946) treated a few cases with total suprarenal cortical extract and noted some improvement of the vascular tone

We have in the past searched in vain for any significant morphological change in the suprarenals in cholera by ordinary staining methods The recent paper by Stoner et al (1953) prompted us to try their histochemical methods on our cholera materials. A preliminary report of our findings was read at the fifth annual meeting of the Indian Association of Pathologists

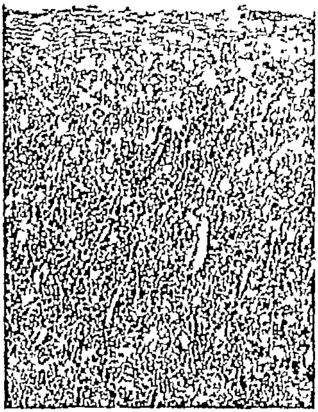

Fig. 2—Suprarenal gland in cholera showing complete depletion of sudanophil material (no black stain) Details as in fig 1

Materials and Methods

We studied eleven pairs of suprarenal glands from bacteriologically positive cases of cholera fatal within 48 hours after onset in the stage of shock Ten pairs of glands from patients dying within 15 minutes of injuries from street or railway accidents served as controls None of the patients was aged less than 10 years and the controls showed no gross pathological changes except those of their injuries The necropsies were done 24–48 hours after death on bodies kept in the cold chamber Five frozen sections from different blocks of each gland were prepared for the detection of neutral fat by staining with Sudan IV, of cholesterol with digitonin seen by polarised light and of ketosteroids with 2 4 dinitrophenylhydrazine No attempt was made to ascertain the weights of the glands the thicknesses of different zones or the cell-size

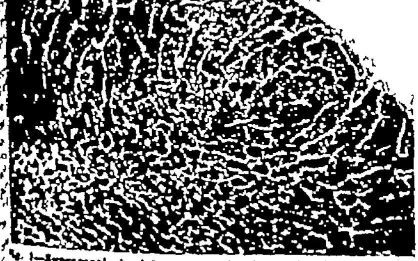

Fig. 1—Suprarenal gland from control dying within 15 minutes of a severe street injury Black stain shows sudanophilia. Frozen section 20 µ thick. (Sudan IV × 70.)

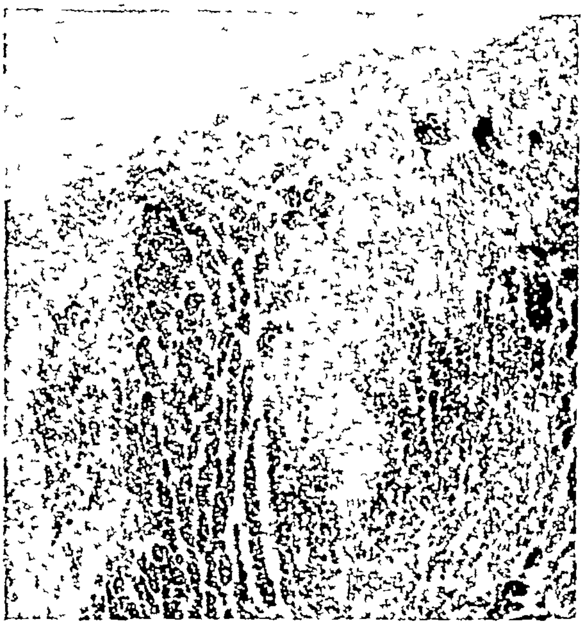

Fig 4—Patchy disappearance of sudanophil material in suprarenal gland in cholera. Details as in fig 1

Results

In four cases there was evidence of complete depletion of neutral fat from all the zones (figs 1 and 2) Only an occasional cholesterol crystal could be made out here and there Staining for ketosteroid showed a faint pale yellow coloration

In five cases neutral fat was seen to have disappeared in patches of varying extent—either wide areas still retained it, or wider areas had only small islands of it left here and there (figs 3 and 4) In one case loss of neutral fat was confined to the zona glomerulosa (fig 5) This patient received only $1^{1}/_{2}$ pints of saline solution before he died, in contrast to 4–38 pints received by other patients in 1–3 days In all these cases ketosteroid and cholesterol showed patchy distribution, but evidence of depletion of cholesterol was much more striking (figs 6 and 7)

In the 11th case all the zones retained sudanophil material while cholesterol crystals were confined to the zona glomerulosa only (fig 8)

One constant finding was that, whereas the neutral fat in the control glands appeared large and globular, that seen in cholera was always smaller and granular (figs 9 and 10)

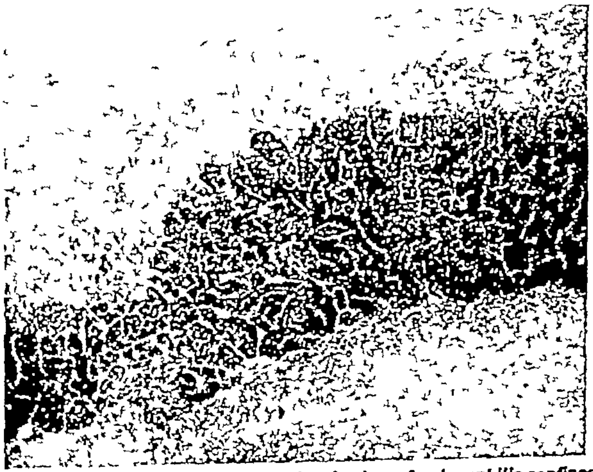

Fig 5—Suprarenal gland in cholera, showing loss of sudanophilia confined zona glomerulosa. Details as in fig 1

Discussion

This histochemical evidence of depletion of lipoid material has generally been thought to be associated with increased liberation of cortical hormone under various conditions Selye (1950) has described similar changes in his experiments on animals with non-specific alarm reaction and has related them to increased activity of the suprarenal glands under stimulation of the adrenocorticotropic hormone of the hypophysis Histochemical reactions have recently been used to investigate the functional state of the gland, but there is no agreement about their specificity Particular importance has been attached to the cholesterol content and its relative distribution An inverse correlation between cholesterol content and secretory activity of the gland has been well established by using stimuli of varying intensity and duration Sayers (1950) regards cholesterol as the precursor of cortical hormone, large stores being held in the suprarenal glands in readiness for emergency periods requiring enhanced synthesis of the hormone We have not estimated the cholesterol content of the glands but have attempted to form an idea from the above mentioned histochemical test, and there is good evidence that it tends to disappear in cholera Staining for ketosteroids may give an idea of the relative amount of the finished hormone available at the moment, but the significance of sudanophil material is not clear. A correlation between change in these lipoids has not always been possible, and Sayers (1950) thinks it is due to slight differences in technique We have, however, found a broadly parallel change in these three materials, although sometimes traces of cholesterol were left when neutral fat and ketosteroid had disappeared, or no cholesterol could be seen in the zona fasciculata, where sudanophil material still persisted Depletion of steroids has, however, been often greater than that of sudanophil material Ayres et al (1951) noted the same in acute infections

In one case the zona glomerulosa was depleted of all lipoids, and in another this zone alone showed crystal

Fig 6—Birefringent crystals of digitonin cholesterol seen in polarised light suprarenal gland from control. Frozen section 25 μ. (× 70)

Fig 7—Well marked loss of birefringent crystals from suprarenal gland in cholera. Details as in fig 6.

cholesterol. The former patient received only 1½ nts of saline solution during his short stay in the spital, and the latter received 24 pints in 46 hours It tempting to think that the *zonal picture in the two* ses was caused by hyponatræmia in the former and pernatræmia in the latter It should, however, be membered that the blood sodium level was not timated in any of these cases that only two such cases ere observed and that the question of zonal autonomy ill remains an enigma (Sayers 1950), so it will be rash draw any conclusion *from this observation*

The over-all picture seen in cholera suggests that the uprarenal glands play an active rôle in cholera by nhanced synthesis of its hormonal products This oncept finds support in another recent observation in his laboratory (De et al. 1955) on the hæmatological hanges in untreated cases of cholera Cholera is not ssociated with *suppuration or emigration of leucocytes* nywhere into the tissues yet the blood shows a leucocytosis which is much more than can be explained by simple hæmoconcentration At the same time there are neutrophilia lymphopenia, and eosinopenia Not only are the eosinophils diminished but in many cases they eem to disappear altogether from the peripheral blood. All these *facts are generally regarded* today as convincing evidence of increased suprarenal cortical activity As regards the relation of *Vibrio choleræ* or its products o these various changes, similar blood changes have been found in our vibrio negative cases Besides, no sign of necrosis or hæmorrhage has been seen in the suprarenal glands of cholera patients. These facts suggest that all the *changes in the blood and in the suprarenal glands form* part of a non-specific response on the part of the body to the associated dehydration shock and anoxia

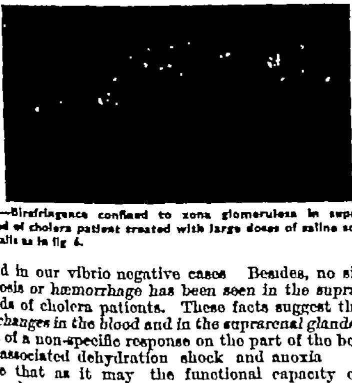

Fig. 8—Birefringence confined to zona glomerulosa in suprarenal gland of cholera patient treated with large doses of saline solution. Details as in fig 6.

Be that as it may the functional capacity of the adrenal cortex, judged by the histochemical techniques does not appear to be the same in all these cases of cholera at the time of death In four cases there was complete depletion of all lipoids—regarded by Stoner et al (1953) as evidence of complete exhaustion Cortical failure may *reasonably be suspected in these cases though* not proved. In the others variable amounts of lipoid are still left indicating that the glands retain some stock of basic elements for responding to further corticotropic stimulation In spite of such potent suprarenal glands, cortical hormonal deficiency may have been responsible for the fatal outcome when the failure may be located at a supra adrenal level

Sevitt (1954) used a combination of adrenaline and corticotrophin tests in fifty four cases of burns and diagnosed adrenocortical failure in five and failure of the pituitary-adrenal axis in two cases *Cortisone therapy* was indicated in the former and corticotrophin in the latter To clarify *the therapeutic implications* of our observations in cholera further investigations into the functional state of the two units of the pituitary suprarenal axis by serial blood-counts with these special methods up to the time of death will be necessary

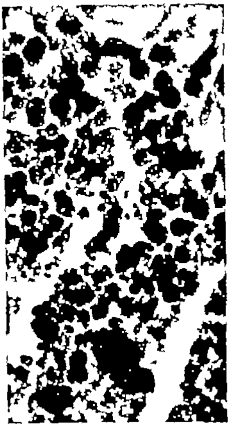

Fig. 9—Sudanophil globules in control suprarenal gland. Details as in fig 1 (× 350)

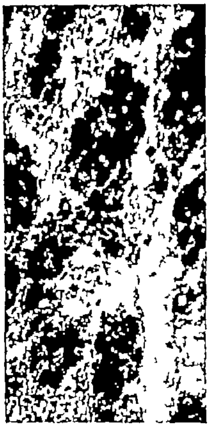

Fig 10—Sudanophil granules in suprarenal gland in cholera. Details as in fig 1

Conclusions and Summary

Evidence of various degrees of depletion of cortical lipoids suggests an active rôle of the suprarenal cortex for enhanced synthesis of its hormones in response to the stress of dehydration, shock, and anoxia of cholera

Further work to inquire into the functional state of the pituitary suprarenal system in cholera is called for

We wish to thank Dr A K. Duttagupta for permission to publish and Mr M Mazumder for the photomicrographs.

CLINICAL EXPERIENCES WITH SOFT-TISSUE PLACENTOGRAPHY

Robert Percival

ASSISTANT RADIOLOGIST

THE LONDON HOSPITAL

Our object is to draw attention again to the advantages of soft tissue placentography which in our experience, has proved a safe and reliable way of establishing the position of the placenta

The work of Reid and of Whitehead on the radiological aspects of soft tissue placentography should leave no doubt as to its reliability simplicity and safety But essential for success is close collaboration between radiologist and obstetrician with interest and confidence equally distributed.

The method is valuable for several reasons. Firstly, the position of the placenta can almost always be seen or be deduced without any other examination It is not disturbing to the patient and in selected cases it may be used for outpatients Secondly it saves beds. Now that antepartum hæmorrhage is managed conservatively patients may have to stay in hospital for as long as six weeks before the fœtus is judged mature enough to risk premature delivery after examination under anæsthesia Soft tissue placentography can greatly reduce such use of valuable beds in non-toxic antepartum hæmorrhage, once placenta prævia has been excluded and bleeding has ceased the patient can safely be sent home Thirdly, it saves patients from wasting time unnecessarily in hospital No longer need a patient who has bled a little at 32 weeks, but is otherwise normal, be kept in hospital for weeks If bleeding is very slight or has stopped, it is quite easy to decide the position of the placenta within half an hour of the patient's admission It cannot be denied that up to the 34th week of pregnancy the method is not always as accurate as it is after this time, this applies to the borderline case in which the placenta appears to dip just beneath the brim, especially when it is anterior Radiography two weeks later will often show the placenta wholly above the brim, as if it had risen as the lower segment became more differentiated Finally, soft tissue placentography is a useful means of finding out whether the position of the placenta, even when in the upper segment, is responsible for a particular presentation or lie (Stevenson 1951) Moreover, it often explains why version has not been successful, and if a second attempt at version is made the dangerous placental site can be avoided

Recent Work

Chief credit for redirecting attention to this essentially simple technique must go to Reid (1949) and Whitehead (1953) The methods involving artificial-contrast media (amniography, cystography, and intravenous placentography) have been examined thoroughly by these workers, who found that they lacked simplicity and accuracy and accordingly were unsuitable for routine use Reid and Whitehead independently followed the lead of Snow and Powell (1934) and others, by making the fœtus serve as its own contrast medium and by deducing the position of the placenta from its displacement of the fœtus The need for such a technique was emphasised when Moir (1944) proved that the uterine wall, the liquor amnii, and the placenta have identical radiographic density, and that consequently no hope could be held out for ordinary soft-tissue methods in locating the placental site

In addition to the valuable radiographic density of the fœtus, use is made of another of its properties—its molecular density, which is greater than that of the fluid surrounding it The fœtus sinks to the lowest point of the amniotic cavity, and by changing the patient's position any area of the uterine wall can be examined against the outline of the fœtus

Clinical Indications for Placentography

275 cases were studied over the three-year period 1951–53 At first the patients were carefully selected, but when we became more familiar with the technique we used it more widely During the early part of the trial the method was not used by every member of the unit, so the series cannot be said to include all examples of the different clinical problems which we investigated After the first six months all patients suspected on clinical grounds of having placenta prævia were submitted to placentography The following list gives an idea of the type of case where we considered it an advantage to discover the position of the placenta

(1) Antepartum hæmorrhage, where the precise diagnosis is in doubt
(2) Unexplained displacement of the presenting part
  (a) High head
  (b) Recurrent malpresentation.
(3) Cases of (1) and (2) combined
(4) Unexplained breech presentations
(5) Unexpected failure of version
(6) Cases due for surgical induction (especially by the Drew Smythe catheter) in which the presenting part is unengaged
(7) Other indications

(1) *Antepartum hæmorrhage, where the precise diagnosis is in doubt*

This is by far the most important indication. When local causes have been excluded there remain, for practical purposes, only two conditions to differentiate—accidental hæmorrhage and placenta prævia Placentography will immediately indicate the position of the placenta There are other signs of diagnostic value when the placenta occupies the lower segment, especially in the last few weeks of pregnancy, but before this the presentation is not expected to be stable, and it is in these very cases, especially when the placenta is on the anterior wall, that physical signs are equivocal and placentography is of the greatest value

Again, bleeding thought to be caused by toxæmia may in fact be due to placenta prævia In this series the combination of toxæmia with placenta prævia was found only twice, and in neither instance was there any evidence of accidental hæmorrhage Bender (1953), on the other hand, found that toxæmic accidental hæmorrhage accounted for the bleeding in 10 of 102 cases of placenta prævia

(2) *Unexplained displacement of the presenting part*

(a) *High head*—In the last few weeks of pregnancy, if the head is high and it cannot be pushed into the pelvis, and if no other cause is found, then placentography would be helpful

(b) *Recurrent malpresentation*—The indications here are similar Stevenson (1951) has emphasised the high incidence of a completely fundal or lower-segment location of the placenta in persistent transverse lie

(3) *Case of (1) and (2) combined*

One would expect to find placenta prævia in these circumstances, yet of 38 cases of antepartum hæmorrhage associated with high head or unstable presentation only 13 had placenta prævia, in the remaining 25 the placenta was situated normally One of the criticisms levelled at radiological placental localisation has been that with placenta prævia the diagnosis can be made by abdominal examination Undoubtedly experience and an intelligent application of clinical methods will result in relatively few mistakes The patient who is known to have bled is of course admitted to hospital, but if she has not the obstetrician may become dangerously complacent unless an easy and accurate means of detecting a placenta prævia is available Moreover, the very knowledge that unexplained non engagement of the head can exist in the absence of placenta prævia may provide a ready excuse for not investigating further, and so defeat the most effective means of lowering the fœtal and maternal death rate from placenta prævia—namely, that of diagnosing it and admitting the patient to hospital before any bleeding has taken place

(4) *Unexplained breech presentations*

Stevenson (1951) has shown that the commonest site for the placenta in persistent breech is the uterine cornu and he has suggested that this causes such alteration in the shape of the uterine cavity that the fœtus is accommodated more readily as a breech In the few cases investigated we have confirmed the preponderance of the cornual position and have found placenta prævia relatively infrequently (table III)

(5) *Unexpected failure of version*

It is not uncommon to fail unexpectedly to turn a breech that has been judged suitable for version, even after it has been disengaged There are probably several reasons for this, but the most likely is that the bulk of the cornual placenta impedes the passage of the head, or so obscures the upper pole that it cannot be grasped easily. If further attempts at version are to be made, it is clearly of value to know on which side the placenta lies, so that it can be avoided It is even more important to exclude o presence of placenta prævia (unusual though it is th a breech) before making further attempts, especially anæsthesia is contemplated

) *Cases due for surgical induction in which the presenting rt is unengaged*

A not uncommon type of case is that in which there toxæmia necessitating induction but the head is not gaged though it can be pushed in In such circumstances acenta prævia can often be excluded clinically but it is ll possible for a placenta on the posterior wall to extend w enough to be disturbed by a Drew Smythe catheter bviously, it would be valuable to know that the placenta elsewhere and out of range (only then indeed should a Drew Smythe catheter be used) Bender's figures 953) relating to the cause of bleeding in placenta prævia phasise the danger of using this instrument in unsuitle cases

) *Other indications*

(a) *Previous classical cæsarean section.*—Since rupture the uterus is thought to be more common if the acenta is implanted on the uterine scar it is as well to ow the placental location in the latter weeks so that e risk may be lessened by admitting the patient to spital before term

(b) *Situation of placenta when it is prævia.*—When acenta prævia has been diagnosed by placentography e actual extent of the placenta on the anterior wall is own before operation and the technique can be anned so as to minimise maternal and fœtal blood loss. acentography may also be considered a useful prelimin y when cæsarean section is to be done under local algesia

(c) *Antepartum hæmorrhage especially before the 36th ek*—If placentography is done routinely a radiograph the fœtal skeleton is automatically available Gross ngenital abnormalities (which are more common when e placenta is prævia) may be seen and useless con rvative management for the sake of the fœtus thereby oided.

Results

PLACENTA PRÆVIA

Of 50 cases of placenta prævia (table I) 1 was missed, ving a 2% error for placenta prævia The mistake was ade early in the series and was due entirely to inexrience in interpretation Nothing similar has happened since and in cases of significant placenta prævia in the last 6 weeks of pregnancy the error should be nil Where the diagnosis is on the borderline this should be made clear in the radiological report Such cases are found mostly when placentography is undertaken too early in the last trimester, before the lower segment has become well formed In a few cases the condition is truly borderline—that is to say, the head is displaced only a little from the symphysis or promontory when the placenta extends down the anterior or posterior wall The level of the upper boundary of the lower segment is undoubtedly variable but in this technique it is assumed always to be at the pelvic brim The vagueness of this important landmark makes it all the more desirable for radiologist and obstetrician alike to be guarded in the special circumstances already mentioned before stating categorically that the placenta does not reach into the lower segment, and to be prepared to make a diagnosis of ' borderline placenta prævia

In this series the radiological diagnosis of placenta prævia was in each instance confirmed or refuted before during or after delivery by examination under anæsthesia, cæsarean section or postpartum intra-uterine palpation or by careful inspection of the placenta and membranes Neither of the last two methods is entirely satisfactory In the first place, owing to uterine retraction the placental edge either separated or still attached will often feel uncommonly low at the beginning of the third stage Where possible these findings should therefore, always be confirmed by inspection of the placenta and membranes after delivery Secondly the inspection of the placenta and membranes as a means of confirming the placental level will only be of value when the hole in the membranes has not been grossly enlarged and when the gestation sac has been expelled intact Again after measuring the distance between the placental edge and that of the hole doubt often remains as to whether the placenta did in fact reach the lower segment Where the hole was of average dimensions a distance of less than 2 in immediately placed the case in the category of placenta prævia We therefore conclude that if the diagnosis is not made before delivery in doubtful cases, the doubt will seldom be removed by any postpartum method of examination, including that of injecting the placenta via the umbilical cord with radio-opaque substances (Radio-opaque substances were not used in this series for the method was regarded as having no special merit) Finally even by examining a patient under anæsthesia before delivery it would not always be possible to feel the edge of a placenta that just reached into the lower segment, especially when the cervix is not well drawn up and when the placenta is posterior

Clinical Features

The largest group is that of antepartum hæmorrhage alone because the bleeding most commonly began before the fœtus was big enough to be regarded as unstable or unduly high The earliest diagnosis was made at 30 weeks yet strangely enough an even earlier one (at 20 weeks) was made in the next group of antepartum hæmorrhage and high head &c It might be argued that this pregnancy was not far enough advanced for the presentation to be significant yet in central placenta prævia (as this one was) the fœtus will often be found unduly high even at a comparatively early stage The difficulty of trying to rely on abdominal palpation alone to diagnose placenta prævia even when there is both antepartum hæmorrhage and a high presenting part is well shown by comparing the number of cases of antepartum hæmorrhage and high head in table I with that in table II In the placenta prævia series only 13 out of 50 (or just over a quarter) fell into the antepartum hæmorrhage and high head group whereas in the other cases there were 25 out of 84 (or slightly less than a third)—figures which are distinctly comparable.

3rd	3	5 lb. 13 oz	1	0	3	0	0	0
4th	11	6 lb. 11 oz	2	0	14	0	0	0

There were no maternal deaths

Placenta prævia was diagnosed before any bleeding took place in 14 out of 50 cases (or nearly a third), these having been radiographed purely because of the abnormal relationship between the presenting part and the pelvic brim This suspicious sign was acted on with positive findings as early as the 32nd week in 1 instance (and there were 3 others before the 36th week), and as late as the 40th week in another In 7 patients antepartum hæmorrhage was avoided entirely, even though the average maturity at diagnosis in these patients was 35 weeks, and 1 had a 4th-degree placenta prævia No fœtus was lost, and their average birth-weight was 6 lb 11 oz

Accidental Hæmorrhage

Although pre eclamptic toxæmia was found to accompany placenta prævia on 2 occasions, there was no evidence that the bleeding was accidental In fact 1 of these patients had no bleeding at all she had a 4th-degree placenta prævia and was delivered at term (by cæsarean section) of a thriving 8 lb 3 oz baby

Examination under Anæsthesia

This was carried out on 10 patients in whom placenta prævia had been diagnosed radiographically It was done for two reasons (1) to check the radiological findings early in the series (later it was used only in borderline cases), and (2) in the lesser degree of placenta prævia, especially anterior ones, to decide on the best method of treatment Disproportion due to posterior placenta prævia is a definite indication for cæsarean section, as was emphasised by Stalworthy (1951)

Fœtal Abnormalities

The incidence of fœtal abnormalities is known to be raised in placenta prævia Macafee's (1945) figure was 3 4% In this series two developmental abnormalities were found (a hare-lip, and a meningocele) In both cases the placenta prævia was of first degree

Average Birth-weight

The conservative management of antepartum hæmorrhage, particularly when it is due to placenta prævia, is now so well established as to require no further commendation here The average birth-weight of 6 lb 11 oz in our 50 cases of placenta prævia is ample proof of the wisdom of such a policy

Fœtal and Neonatal Deaths

One of the aims in the modern management of placenta prævia is to reduce fœtal and infant loss without adding extra risk to the mother The mortality-rate of 16% in this series compares favourably with that in other reported series The average birth-weight of the fœtuses and infants lost was 5 lb 5 died after birth, the only abnormal finding being prematurity 3 were stillborn—1 from prolapse of the cord, 1 macerated from placental infarction, and 1 from the cord being tightly round the neck Table I shows that the loss was fairly evenly divided between the different degrees of placenta prævia It is unfortunate that 3 of the neonatal deaths followed cæsarean section In 6 of the patients concerned, active measures had to be undertaken to combat recurrent severe bleeding

Treatment

There were 31 cæsarean sections 14 were for 4th-degree and 3 for 3rd-degree placenta prævia Of the 8 done for 2nd degree, 1 was for a breech in an elderly primigravida, 3 were for posterior placenta prævia with apparent disproportion, and 4 were for excessive bleeding after artificial rupture of the membranes had failed to stop it In the other 2nd degree cases, bipolar version was done once when artificial rupture of the membranes did not stop the bleeding, simple artificial rupture of the membranes was also done, and in the remaining 3 cases no treatment was required 6 cæsarean sections were done for 1st-degree placenta prævia—2 for excessive bleeding, 2 for unstable presentation, 1 for associated diabetes mellitus, and 1 for prolapse of the cord

Maternal Deaths

There were no maternal deaths associated with pla prævia

Incorrectly Diagnosed and Borderline Cases

Case 1 —A para 5 with antepartum hæmorrhage, and fœtal head at 34 weeks Placentography showed a pos placenta, the head was displaced significantly, but th erroneously thought to be due possibly to clot B continued, and examination under anæsthesia show marginal placenta prævia Artificial rupture of the mem and bipolar version stopped the bleeding, but an [illegible] infant of 4 lb 3 oz was delivered, which died after [illegible] hours This case was one of the earliest in the series Th mistake was not in technique but in interpretation, and w due entirely to inexperience

Case 2 —A para 2 with antepartum hæmorrhage at [illegible] weeks Placentography revealed no significant displace of the head, and it was reported as showing "no evide placenta prævia" The patient subsequently had a nor labour with no further bleeding, but postnatal inspectio the placenta suggested that it was low lying—possibly 1 degree The infant weighed 6 lb 1 oz and did well.

Case 3 —A primigravida with a high head at term. Pla tography showed an anterior placenta and no significan placement Normal delivery took place with no bleeding, b there was a 40 oz postpartum hæmorrhage Postpar intra-uterine examination suggested that the placenta just reach into the lower segment anteriorly and was po a 1st-degree placenta prævia The infant weighed 10 lb. 1 and did well

Case 4 —A primigravida with antepartum hæmorrhage a high head at 35 weeks Placentography showed a pos placenta and there appeared to be no significant displace from the promontory to suggest that the placenta reached the lower segment The patient was examined under an thesia, and a thin edge was thought to be felt high up teriorly A 5 lb 9 oz infant was delivered spontaneous and it did well. There was no report of a postpartum inspe of the placenta and membranes to confirm this case

undal	0	Posterior and fundal	1
ower segment	2	Cornual	25

The only serious error in these so-called missed "cases," s made in case 1 and was due to inexperience in erpretation None of the other 3 behaved subsequently e placenta prævia cases and if in fact they were y were not of significant degree and would be correctly sed as borderline only No fœtus or mother suffered a result of the error for although the baby in case 1 d, the negative radiographic findings encouraged the ntinuation of conservative treatment to avoid pre aturity It was further bleeding that caused the birth a fragile premature infant

ANTEPARTUM HÆMORRHAGE NOT DUE TO PLACENTA PRÆVIA

There were 84 cases of antepartum hæmorrhage not to placenta prævia (table II) *In 82 a correct diagnosis* s made by radiography leaving 2 cases incorrectly gnosed 1 was a borderline case at the 39th week, d little time was wasted by *the patient in hospital.* e other, unfortunately spent four weeks in hospital ecessarily, through an error due to inexperience in chnique Of these 84 cases the absence *of placenta* evia was confirmed in 45 (table II) All the other cases haved quite normally and gave no indication of low plantation

use of Antepartum Hæmorrhage

In only 3 patients were there signs of toxæmia, and in h instance examination of the placenta after delivery ongly supported a diagnosis of toxæmic accidental morrhage It is significant that the commonest ociation was with external cephalic version The se of the bleeding was not found in 65 of the patients

ition of the Placenta in the Upper Segment

It was thought that non toxæmic antepartum hæmor ge might be associated with the position of the placen site A likely position would seem to be *the anterior* rine wall reaching nearly to the pelvic brim : there placental site would be vulnerable to trauma and be r enough to the cervix *for the blood to escape readily* ble III shows that the commonest site for the placenta non toxæmic antepartum hæmorrhage is, in fact the terior wall extending to the fundus the anterior ll is the next commonest

ditional Clinical Signs

As might be expected bleeding was the only abnor l feature in over two-thirds of the cases We have eady drawn attention to how often bleeding and ative displacement of the presenting part can be found ether in the absence of placenta prævia Much portance is attached to this observation for dangerous complacency or over anxious conservatism may result if the precision and safety of soft-tissue radiography is denied both to patient and clinician

Average Stay in Hospital

If by staying in hospital a patient is doing good for herself and for her fœtus then it would be wrong to suggest that she go home But there is no evidence that in the absence of *other symptoms and signs,* there is any advantage in keeping patients in hospital once placenta prævia has been excluded and once bleeding, which is usually slight, has stopped This belief deter mined our policy in this series. Even so the average stay in hospital before the 36th week was reached proved to be as much as 11 days this relatively high figure is largely explained by our having to keep in patients who bled too early for placenta prævia to be excluded radio graphically Even though in 1 instance placenta prævia was excluded correctly at the 26th week, it is unusual to be able to give a positive diagnosis before the 34th The arbitrary time of the 36th week was decided on because those who diagnose placenta prævia by passing a finger through the cervix under anæsthesia usually wait until then to do so

Reckoned Average Time Saved

The saving of 8 days in hospital seems small enough, but with many patients the bed saving is considerable Those who doubt the value of soft tissue placentography say that this aspect of the management should be dis counted ; but it is of real and practical importance both to these patients and to those who are waiting to occupy the beds.

Average Birth-weight

This was 6 lb 6 oz —lower than the reported average *for placenta prævia*

Fœtal and Neonatal Deaths

7 fœtuses and infants were lost giving a figure of 8 3%—about half that for placenta prævia 1 at least of these cases could hardly have had any connection with antepartum hæmorrhage the fœtus, said to have been 6 weeks postmature and weighing 11 lb died during and as a result of a very difficult delivery The other deaths cannot be attributed to our policy of discharging patients who had bled but in whom placenta prævia had been excluded radiographically since all the patients concerned were kept in hospital from the time of bleeding until they were delivered.

Fœtal Abnormality

No developmental abnormality was found in any *fœtus in this group*

Maternal Death

The only mother lost died some 2 months after delivery from ovarian carcinoma with pulmonary metastases

Incorrectly Diagnosed and Borderline Cases

Case 5 —An elderly primigravida with persistent breech presentation at the 34th week and a little bleeding after an attempt at version had failed. Placentography suggested posterior placenta prævia of significant degree but subsequent cæsarean section at term for the presentation revealed an anterior placenta in the upper segment This was again very *early in our series and before* we began to use the tilted lateral view in doubtful cases. A healthy [illegible] lb *10 oz.* baby was delivered. (Eighteen months later significant posterior placenta prævia was again diagnosed in this patient's second *pregnancy* at the 34th week, breech again presenting This time the tilted lateral view was taken and subsequent cæsarean section proved the diagnosis correct)

Case 6 — A para-5 with antepartum hæmorrhage and an unengaged head at the 39th week. The placentographic films were poor in quality and a full view of the uterus was not *available* A borderline posterior placenta prævia was diag nosed. Examination under anæsthesia was done but no placenta was felt (No postpartum examination or inspection of the placenta and membranes was recorded to confirm this finding) A healthy 7 lb 13 oz infant was subsequently delivered

HIGH HEAD, BREECH, OR UNSTABLE PRESENTATION, &C

The primary indication for placentography in this group (table III) was either an unduly high presenting part, or an unstable presentation suggesting the possibility of a low-lying placenta, in the absence of any other detectable cause Mostly the patients had reached the last month of pregnancy, but in some placenta prævia was suspected well before the 36th week, solely on the relationship of the presenting part to the brim As table I shows, 1 case of placenta prævia was suspected and proved by radiography as early as the 32nd week The patients who had a pelvic tumour were radiographed both to test the technique in these circumstances and to exclude the co-existence of placenta prævia Of 113 cases, radiographic localisation of the placenta was correct in 109 In only 1 case was the diagnosis said to be incorrect

Case 7 —A para 3 with an unstable presentation at 36 weeks Posterior placenta prævia was diagnosed by placentography, but near term the fit of the head threw doubt on the diagnosis, so artificial rupture of the membranes was done to stabilise the presentation When labour began, bleeding was so severe that cæsarean section was undertaken. The surgeon, however, was of the opinion that the placenta did not reach the lower segment No cause for the bleeding was suggested, and we offer no other explanation There were no signs of toxæmia, and a healthy 7 lb 2 oz infant was born

The other 3 cases were essentially borderline 1 of them, case 3, has already been discussed

Case 8 —A para 2 with a very unstable presentation at 35 weeks Placentography was reported as showing a minor degree of posterior placenta prævia There was no antepartum hæmorrhage or any departure from normal in the subsequent labour at term, when a healthy 6 lb 8 oz infant was delivered No postpartum intra uterine or placental examination was recorded This, therefore, must rank as an error in diagnosis, although it is possible that such a minor amount of placenta dipping below the brim might either have been carried up later by uterine growth, or been so slight as to cause no trouble

Case 9 —A primigravida with a high head at 39 weeks Placentography suggested a minor degree of posterior placenta prævia, because of slight forward displacement of the head and the placenta occupying the posterior wall No bleeding took place during labour, which began at term, but the head engaged slowly Delivery was uneventful Unfortunately there is no record of examination after labour

No mother or fœtus was lost as a result of these debatable errors No gross mistake was made in missing significant placenta prævia The errors, as they should be in this work, were rather those of commission than omission When there is doubt, "placenta prævia" should be diagnosed Just over half of the cases were confirmed by one or other of the usual methods In the remainder there was no departure from normal to suggest a low-lying placenta The different reasons for the ill-fitting or abnormal presenting part are shown in table III In about half no cause was found This is too high a proportion and simply means that such common conditions as multiparity, occipitoposterior, pelvic inclination, and hydramnios have not been recorded in the notes

Table III also shows the comparative rarity of breech presentation in placenta prævia or contracted pelvis and pelvic tumour on the one hand, and the significant coincidence of cornual implantation and breech presentation on the other Of the 35 cases of breech presentation investigated, the placenta occupied the cornual position in no less than 24 In our series, as in Stevenson's (1951), this position was the commonest finding associated with breech presentation, and it is the most probable cause of persistent breech presentation The placental position in the [illegible] cases is shown in table III In 1 case there was both pelvic tumour and cornual implantat but precedence has been given to the tumour as the c of the breech

Further Points

Transverse or Oblique Lie

The very essence of soft tissue placentography is t use the contrasting outline of the fœtus to show by displacement the position of the placenta Unless lie is axial, with the lower pole over the brim, the imp tant brim area cannot be examined accurately, and the obstetrician should be present in the X ray depart to correct the lie immediately before placentography

Pelvic Tumour and High Head

Obviously the diagnosis of pelvic tumour will be ma by clinical examination, but it is not by any means ea to exclude the co existence of placenta prævia clinical Even when the radiologist knows of the presence of pelvic tumour, if the placenta extends well down the posterior wall it is not always possible to be sure that some of the head displacement is not due partly to placenta prævia The same is true when the head is displaced by a rectum grossly distended by fæces The difficulty does not arise when the placenta is on the anterior wall or fundus, for the radiologist can then diagnose the cause of the displacement with confidence In practice, from the aspect of delivery, it is of no importance to distinguish between tumour and placenta prævia, because cæsarean section will be needed in both However, for safe ante natal management it is important to know of the possibility of placenta prævia

Early Diagnosis

Before about the 34th week precise diagnosis can made only when the placenta is implanted mainly arou the fundus, or mainly in the lower segment Even wh *the placenta appears to extend from the* anterior posterior walls into the pelvis, at this early stage it impossible to predict how much will remain there as t *uterus grows and the lower segment forms* Natura if a case is borderline so early it will almost certain become negative for placenta prævia at a later date wh *further placentography should be done* A correct dia nosis was made in 5 of our patients by the 30th week In 3 placenta prævia was excluded, in 2 major place prævia *was discovered, and both* subsequently need cæsarean section

Placenta Prævia and the Presenting Part

The relationship of the presenting part with the pe brim is used both clinically and radiologically to det placenta prævia, and the more experienced a clinic becomes the closer will he approach the precision placentography, yet it is only in the more extrem forms of placenta prævia that he is likely to achieve comparable degree of success Similarly, it is only wh the presenting part is deeply engaged and can be palpat readily through the fornices that placenta prævia ca be excluded as the cause of bleeding in a particul patient In between these extreme examples are fou *the majority of cases of antepartum* hæmorrhage, a clinically there must be doubt about the position of th placenta Even when the head can be engaged read at term there can still be significant placenta præv The following case is an example of this

Case 10 —A para 1 had a little vaginal bleeding at ter The head was resting in the brim and could be enga readily The placentography report stated there was signifi displacement compatible with the presence of posterior plac prævia Cæsarean section was done and a posterior mar placenta prævia was found

Radiological Technique

The technique used was essentially that described Reid (1949) and by Whitehead (1953), but we redu the number of films taken to two—an anteroposter d a standing lateral which included the whole of the erus and the pelvic inlet In some a third view was eded—the tilted lateral where the standing lateral ows apparent forward displacement Very occasionally her views may be required in cases of hydramnios

High kilo voltage (115–120 kV) is used for lateral ws. Development is cut to 3½ min to avoid over ckening of the part of the film which shows the terior wall

The patient must empty the bladder immediately fore examination If the rectum is too full of fæces e procedure may have to be repeated.

Summary

Soft tissue placentography is a practical method of ating the placental site The margin of error is siderably less than with clinical methods.

Its advantages are greatest in the conservative manage nt of antepartum hæmorrhage

In cases of major degree placenta prævia the hazards digital exploration of the lower segment can be avoided ogether Only in lesser degree or borderline placenta evia, in which the risk of severe bleeding is propor nately less, may examination under anæsthesia be eded, either for final diagnosis or treatment.

The method has proved particularly useful in patients pected of having placenta prævia before they have d.

That certain placental positions may cause persistent ech presentation has been confirmed by our observa ns No association was found between the placental e and accidental antepartum hæmorrhage

TREATMENT OF ADRENOGENITAL SYNDROME

WITH CORTISONE AND ŒSTROGEN

C N Armstrong
M.D Durh F.R C.P D.P.H
PHYSICIAN ROYAL VICTORIA INFIRMARY
NEWCASTLE UPON TYNE

h cases of adrenogenital syndrome presenting female udohermaphroditism due to hyperplasia of the adrenal ıds, continuous treatment with cortisone reduces the kal masculine features and the urinary excretion 17 ketosteroids and promotes the development of inine characteristics (Wilkins et al 1950 1951 1952, Vines and Dods 1954) To obtain this result large doses of cortisone (100–200 mg daily by mouth) may have to be given, and this presents difficulties where supplies of cortisone are restricted

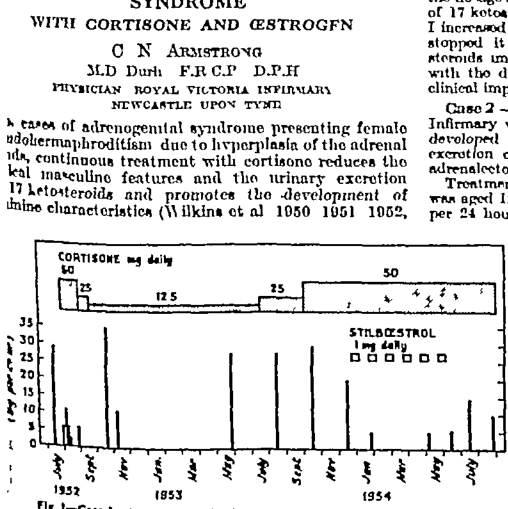

Fig 1—Case 1 : treatment and urinary excretion of 17-ketosteroids.

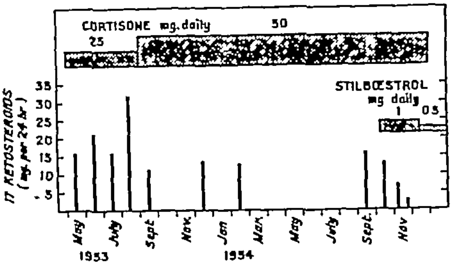

Fig. 2—Case 2 : treatment and urinary excretion of 17-ketosteroids

Treatment of such cases with œstrogen alone produces neither clinical improvement nor reduction in the excretion of 17 ketosteroids. In the following three cases, however combined therapy with œstrogen and cortisone was successful.

Case 1 —A girl aged 10 years, was admitted to the Royal Victoria Infirmary Newcastle upon Tyne with male body contours, severe hirsutism pubic hair of male distribution, undeveloped *breasts, and urinary excretion of 17 ketosteroids* 36 mg per 24 hours A congenitally large clitoris had been amputated

Laparotomy revealed uterus vagina, and ovaries Right adrenalectomy was performed but produced no improvement

Treatment with oral cortisone was begun with 50 mg daily in 1952, when the patient was 16 and the urinary excretion of 17 ketosteroids was reduced from 29·0 mg to 2 8 mg The dosage of cortisone was reduced to 25 mg and later 10 mg daily with no change in the clinical picture The excretion of 17 ketosteroids increased to 30 mg ; so the cortisone dosage was increased to 50 mg daily When the excretion of 17 ketosteroids was 21 mg under this dosage of cortisone I prescribed (for acne) 1 mg of stilbœstrol *daily for 14 days followed by 14 days without stilbœstrol,* the dosage of cortisone remaining 50 mg daily The excretion of 17 ketosteroids decreased rapidly to 4 5 mg in 24 hours I increased the dosage of stilbœstrol to 2 mg daily and then stopped it whereupon the urinary excretion of 17 keto steroids immediately began to increase (fig 1) Coincident with the decrease in excretion of 17 ketosteroids there was clinical improvement

Case 2 —*A girl aged 9 was admitted to the Royal Victoria* Infirmary with a deep voice a hypertrophied clitoris, well *developed pubic hair ; the vagina was present* Urinary excretion of 17 ketosteroids 23 6 mg per 24 hours Left adrenalectomy did not produce any clinical improvement

Treatment with cortisone was started when the patient was aged 12 and her excretion of 17 ketosteroids was 10 mg per 24 hours. The dosage was 25 mg daily and was later increased to 50 mg daily The excretion of 17 ketosteroids fluctuated somewhat but the smallest amount excreted was 11 mg in 24 hours and the girl's breasts began to develop when the excretion of 17 ketosteroids was 15 3 mg Stilbœstrol 1 mg daily was prescribed in addition to the 50 mg of cortisone daily and the excretion of 17 ketosteroids decreased to 6·8 mg *and later 2 3 mg per 24 hours (fig 2) Menstruation was also* established.

Case 3 —In this girl an enlarged clitoris was found at the age of 1 year and pubic hair began to grow at the age of 2½ years In 1953 when she was aged 14 treatment was started with oral cortisone 50 mg daily The excretion of 17 ketosteroids decreased from 23 0 mg per 24 hours to 13 2 mg *and later* to 7 8 mg but increased again to 10·5 mg The breasts began to develop and menstruation

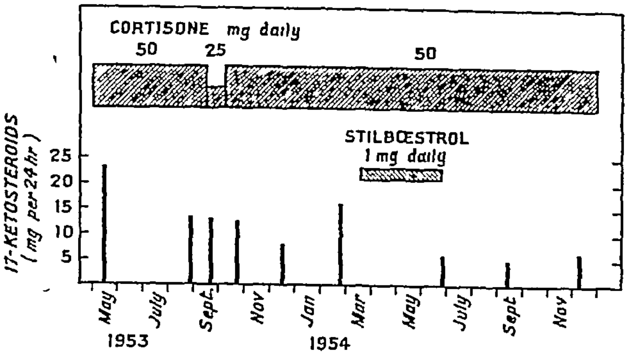

Fig 3—Case 3 : treatment and urinary excretion of 17-ketosteroids

was established With the dosage of cortisone kept at 50 mg daily stilbœstrol 1 mg daily was prescribed, and the urinary excretion of 17 ketosteroids decreased to 6 0 mg per 24 hours (fig 3) Stilbœstrol therapy had to be stopped then because of heavy menstrual bleeding

These cases show that, in the treatment of female pseudohermaphroditism, administration of œstrogen and cortisone is more effective than cortisone alone in reducing a high urinary excretion of 17-ketosteroids

MASSIVE BLOOD-TRANSFUSION THROUGH THE CEPHALIC VEIN

E G Dolton
M B Lond , F R C S
THORACIC SURGEON, ROYAL HOSPITAL, WOLVERHAMPTON

Patients undergoing major thoracic surgery may need very rapid transfusion of considerable quantities of blood Cannulation of the internal saphenous vein at the ankle leads to a disappointingly slow flow In the commonly favoured lateral position this may be partly due to compression of the saphenous vein at the knee and in the thigh by the opposing limb or an intervening pillow, and also possibly the opened chest and relaxed abdominal muscles lessen the negative pressure responsible for normal systemic venous flow Needling of an arm vein is more effective but often unsatisfactory Intra arterial transfusion gives a rapid replacement of blood lost by major cardiac or vascular injury but is not easy to do, requires a special pump and expert medical su and leads to an excess of potassium in the p (Melrose and Wilson 1953)

What is wanted is a large cannula inserted into a superficial vein reasonably near the heart No the inferior vena cava is of use, but the external vein and the cephalic vein near the shoulder satisfy criteria Use of the external jugular would lead to on the neck , therefore the cephalic vein is to be I was encouraged to use this vein by Dr N H then casualty registrar to this hospital, who told had given infusions through the cephalic vein successfully in cases of burns

My assistants and I have cannulated the cephalic in over 100 cases in the past twelve months. The runs very freely, venospasm has not occurred, and pint of blood can be completely transfused within minutes without any form of pressure The vein is thin-walled, easily dilated at the site of tion, and admits an unexpectedly large cannula ease This method has proved eminently satisfactory without any complication, and I recommend it to engaged in major surgery and not blessed with assistants

The only disadvantage has been that on nine the cephalic vein has been absent from its normal tion Such patients have had small transverse taneous veins across the front of the shoulder, and I not now explore for the cephalic vein when such present

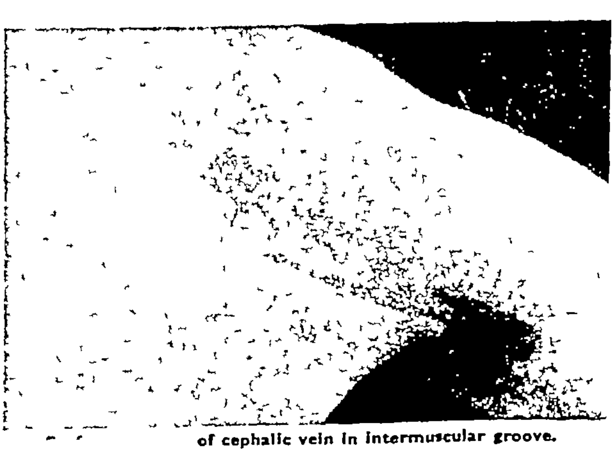
Anatomy

The cephalic vein begins on the radial side of dorsum of the hand, runs up the radial side of the and at the bend of the elbow gives off a median branch medially to join the basilic vein Thereafter travels up the outer side of the arm lateral to the muscle until it crosses the anterior aspect of the of the deltoid muscle , it next approaches from lateral side the groove between the deltoid muscle the pectoralis major muscle, and soon runs in the itself (see figure) , about two inches higher the sinks deeply into the groove and becomes difficult to by ordinary dissection No artery accompanies it. ever deepening course leads it to the coracoclav fascia, which it pierces, and it ends in the subcl vein The junction of tributary with recipient vein be guarded by valves, but these are often absent

This description is based on surgical exploration on several post-mortem dissections

Procedure

It has been found convenient to cannulate the when general anæsthesia has been induced and with patient supine The arm which will be uppermost operation is selected, because flexion and compress the lowermost arm has caused angulation of the and failure of the drip With the arm held away from side of the body at about 45° (most easily accompl by placing the hand under the upper part of the an incision 2 inches long along the lower part of deltoideopectoral groove, and extending just below beginning of that groove, will expose the vein If vein is not in the groove it will be found slightly laterally, over the deltoid muscle The vein is thin easily dilated, and in an adult takes the largest Bailey cannula , the medium Bailey cannula and normal adult Sutton cannula can usually be introd into the vein of a child aged 5–10 years After I customarily insert a distal skin stitch which holds cannula in its second loop, and a proximal skin which, passing under the vein, is left long and until after the cannula has finally been removed



of cephalic vein in intermuscular groove.

THROMBOCYTOPENIC PURPURA SSOCIATED WITH OXYTETRACYCLINE THERAPY

A G BECKETT
B.M Oxf'd M.R C.P
IOR MEDICAL REGISTRAR, ROYAL FREE HOSPITAL, LONDON

A. W H. FOXELL
M.B Lond
MATOLOGIST, NORTH WESTERN GROUP LABORATORY LONDON

ALTHOUGH oxytetracycline is known occasionally to use toxic reactions in the skin and gastro intestinal act, no case of blood dyscrasia (including thrombo topenic purpura) due to this drug has been reported in is country

In a nation wide survey of 1448 cases of blood dyscrasia the United States, Welch et al (1954) report 41 cases of blood orders associated with oxytetracycline therapy including cases of thrombocytopenia in 4 of which no other drug s given. The outcome and details of these cases are not ported. Of the 409 cases of thrombocytopenia 62 were ssified as due to 'infection' and 266 as idiopathic It is refore possible that some or all of the cases associated with ytetracycline therapy should have been classified under ther of these headings.

We describe here a case of thrombocytopenic purpura ssibly due to oxytetracycline

Case-report

A man, aged 77 was admitted to hospital on Oct 19 1954 th bilateral pneumonia, which had started 10 days earlier th tiredness followed 3 days later by pain in the chest and termittent ache in the right ear For at least 10 years he had d Paget's disease of bone 3 years previously he was found have diabetes mellitus, which was subsequently treated by et alone. There was no history of any tendency to morrhage.

On admission his temperature was 99°F pulse rate 100 d respirations 28 per min. He was flushed and dyspnœic th signs of consolidation at the left base and coarse crepita tions with expiratory rhonchi at the right base He had a llapsing pulse and blood pressure 160/70 mm. Hg Paget's sease of the tibiæ was present the changes being more onounced in the right leg There was no retinopathy the ee and ankle jerks were absent but vibration sense was sent.

vestigations

Radiography of the chest showed extensive pneumonic anges in the lower zones, greater on the right side On ct 20 the hæmoglobin was 90% (13·3 g per 100 ml) and the hite cells were 9900 per c.mm. (differential count of normal stribution); the erythrocyte-sedimentation rate (E.S.R.) as 120 mm. in 1 hour (Westergren) The serum alkaline osphatase level was 9·5 King Armstrong units per 100 ml he sputum contained scanty pus cells and on culture grew *reptococcus viridans* Cultures of swabs from ear and eye re sterile

reatment and Progress

Treatment with penicillin and sulphadiazine started on the ening of admission by his private doctor was continued r 24 hours; but as there was no improvement and his ndition was serious, these drugs were stopped and he was ven a course of oxytetracycline 1·0 g initially followed by 5 g. twice daily Little or no improvement followed at first ute otitis media was diagnosed on Oct 24 and was treated ith chloramphenicol in propylene glycol which was applied to e auditory meatus on a wool wick 6 hourly for 18 hours. yringotomy was then performed under general anæsthesia nd the discharge stopped a few days later

On Oct. 26 the patient had acute cardiac failure which proved after venesection and administration of oxygen and travenous aminophylline Subsequently he was treated ith digitalis and mersalyl and had no further episodes. ecause of the severity of the illness and this episode of rdiac failure the dosage of oxytetracycline was increased 5 g 6 hourly being given for the next 6 days. This produced clinical improvement the symptoms decreasing and the temperature which had been 99–100°F falling to normal The signs in the lungs did not change however and radiography showed increased shadows in both lower zones extending into the mid zone on the left

The white-cell count, which on Oct 27 was 21 000 per c.mm (neutrophils 91%) fell to 10 000 per c.mm. 9 days later The E.S.R. was now 65 mm. in the first hour The sputum again produced a heavy growth of *Strep viridans* Oxytetracycline was continued on a reduced dosage 1 g daily in two divided doses for 8 days making a total of 26 g in 22 days.

Blood Dyscrasia

On the third day after stopping the oxytetracycline the patient had a severe epistaxis followed next day by more epistaxes and gross hæmaturia By this time he had developed extensive hæmorrhagic purpura During the next 24 hours many fresh cutaneous hæmorrhages appeared and the hæmaturia continued At this stage he had normochromic and normocytic anæmia, thought to be due to blood loss The hæmoglobin was 66% (9·8 g per 100 ml) red cells were 3 270 000 per c.mm and white cells 18,000 per c.mm (neutrophils 63%); *his platelets had decreased to 15 000 per c.mm* The bleeding time was much prolonged no evidence of cessation of bleeding occurring after 18 minutes. The prothrombin time and clotting time were normal and the Hess test was positive Next day there were further skin hæmorrhages and hæmaturia. The hæmoglobin was 63% (9·2 g per 100 ml) platelets were 11 000 per c.mm. and white cells 16 700 In the evening he started to cough up bloodstained fluid and vomited 'coffee grounds.' His general condition deteriorated rapidly and in the early hours of Nov 17 he died

The Sternal Marrow

Sternal marrow puncture was done 15 minutes after death the differential marrow count being as follows: myeloblasts 1% promyelocytes 1% neutrophil myelocytes 8% metamyelocytes 8·5% neutrophil polymorphs 51%, eosinophil polymorphs 1%, early normoblasts 4% intermediate normoblasts 6% late normoblasts 14·5% plasma cells 0·5% lymphocytes 4% and monocytes 0·5% The myeloid/erythroid ratio was 2·9/1 There was no evidence of platelet production, and only an occasional promegakaryocyte was present. No other evidence of toxic changes was seen. The development of the myeloid and erythroid series was normal apart from some increase in mature polymorphs.

Necropsy

There were numerous petechiæ in the skin of the trunk and limbs, the pericardium and endocardium, and the mucosa of the stomach small intestine colon and urinary bladder Ecchymoses were present in the pelves of the kidneys and in the leptomeninges over the left frontal and parietal lobes of the brain The lungs showed organising fibrinous pleurisy and gangrenous pneumonia with abscesses up to 2 cm. in diameter in the lower lobe of the left lung An older unresolved pneumonia, with abscesses up to 1 cm in diameter in the lower lobe of the right lung and œdema and congestion of the remainder of the lungs were also found The spleen showed subacute septic changes. Pus was present in the right middle ear The neck and upper half of the shaft of the right femur and the sternum contained red marrow

Discussion

Thrombocytopenia is occasionally associated with septicæmia but throughout his illness our patient did not show any clinical evidence of this and it seems improbable that the purpura was due to septicæmia He had suppurative pneumonia, diabetes mellitus and Paget's disease of the bone none of which are known to produce thrombocytopenia

Sulphonamides and chloramphenicol cause thrombocytopenia on rare occasions, but we do not think they were responsible for it in this case because the sulphadiazine was given for only 24 hours to a total of 2·5 g and the bleeding did not come on until 3 weeks later Chloramphenicol was applied aurally only on three occasions in 18 hours and this local application could scarcely have had a toxic effect on the marrow

In spite of the widespread use of mercurial diuretics we have found only 3 published reports of thrombocytopenia possibly due to mercurials (Butt and Simonsen

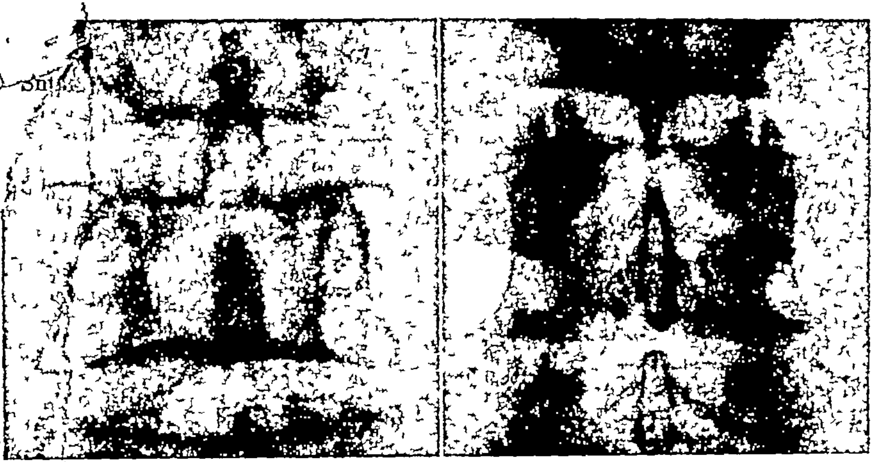

Fig 6—The normal vertebra on the right shows a fine *honeycomb* pattern, in contrast to the osteoporotic vertebra on the left which is less radio-opaque, and shows *relatively few but coarser* trabeculæ *of mainly longitudinal distribution*

stresses are greater up and down the spine *rather* than across The centra become biconcave, with increase in size in the intervertebral discs (fig 7) The centra may show denser end-plates *than normal* The condition is most marked in the spine, especially in the lumbar vertebræ There is a general deformity of the column, which shows a rounded kyphosis A kyphosis may, however, be due solely to disc degeneration There may be a wedge-shaped deformity of individual vertebræ All degrees of collapse occur sometimes the spinous processes become so close together that they develop false joints between them (Other decalcifying diseases, especially osteomalacia, produce similar X ray appearances in the spine, so it is unwise to make *the diagnosis* of osteoporosis on this one observation *alone*) It is usually stated that in osteoporosis the *pelvis may* be slightly affected, but the long bones scarcely ever and the skull almost never Actually, the other bones are affected, but less obviously so

Ghormley, Sutherland, and Pollock (1937) found that of pathological fractures arising from non-malignant conditions, one-third were due to senile osteoporosis, a cause three times as common as the next most numerous group

In patients over the age of 50 admitted to the Radcliffe Infirmary for fractured neck of femur, the condition is three times as common in women as in men It is difficult to believe that the women are submitted to more trauma than the men, and one must conclude that their bones are more brittle This belief is supported by work of Rutishauser and Dufour (1950) who examined patients who had died with fracture of the neck of the femur They cut sections of the necks of the unbroken femurs and found that these always showed characteristic changes including osteoporosis The condition is also found in the arms and legs, if the necessary predisposing factors are present and if it is sought (fig 8) These age changes also occur in compact bone as well as in cancellous bone (Amprino and Bairati 1936)

It must be admitted that the difficulties of determining the degree of osteoporosis by X ray examination are great Cobb (in Cowdry 1952) has described post-mortem chemical analyses of phalanges from patients whose hands had been radiographed during life A just-detectable X-ray difference of the dissected bone corresponded to a chemical difference of 9%, but a just detectable difference in X-ray films of the whole finger corresponded with a 25% difference in chemical analysis must be emphasised that these figures were obtained the most easily X-rayed bone in the body and in a ation where there is more bone than soft tissue Decal- spine must be even harder to detect

Similar experiments have been made by Fusi (1953) He placed complete and sliced lumbar vertebræ in 5% nitric acid, which slowly removed the mineral matter Radiological changes were visible when the isolated vertebræ had lost 3% of their calcium content, but he estimated that in the living subject changes begin to be recognisable only when the vertebræ have lost 60% of their calcium This is a surprising figure, but supporting evidence is provided by some experiments of Ardran (1951) He bored holes vertically through the centra of normal lumbar vertebræ taken from the post-mortem room A hole 3 mm in diameter could be seen clearly in a lateral X ray film of the isolated vertebra, but if the hole was filled with water it was entirely invisible A similar hole 14 *mm* in diameter—i e , about the size of the spinal canal—and occupying about *one* third of the diameter *of the* centrum, was naturally very obvious in *an X ray film* , but when it was filled with water it was *only just* visible as a faintly porotic area If this is so in excised vertebræ, no doubt such X-ray appearances would be even *more* difficult to detect in a vertebra in the body

One may therefore conclude that if there are X ray changes indicating osteoporosis, and particularly if there is vertebral collapse, there must be gross anatomical changes

The Strength of Bone

The mechanical strength of compact bone has been extensively studied, and a remarkable material it is. Its *tensile strength is nearly as great* as that of cast iron and its *crushing strength* three quarters of that of wrought iron (Bell, Cuthbertson, and Orr 1941) It is about three *times as strong as* wood The tensile and compression *strengths of* compact bone are about equal, an unusual *distinction among* building materials

A vertebral centrum consists essentially of a block of cancellous bone, with a very thin outer shell of compact bone and usually weakened by a surprisingly large hole on the posterior aspect for the emissary veins

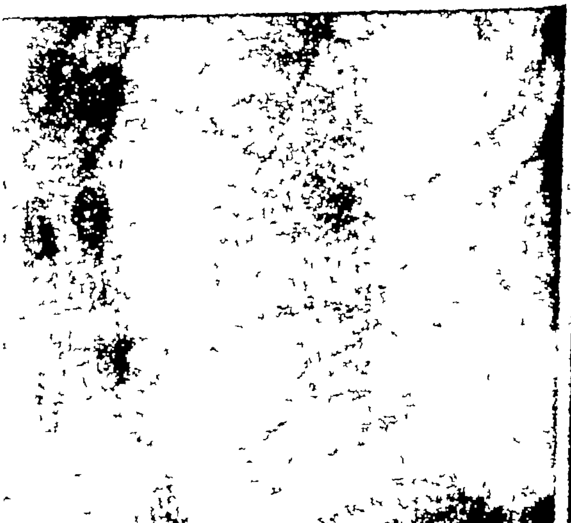

Fig 7—X ray of the thoracic spine of a woman of 73, with a long history of chyrotoxicosis and immobilisation She has a pronounced kyphosis with flattened biconcave *porotic* vertebræ

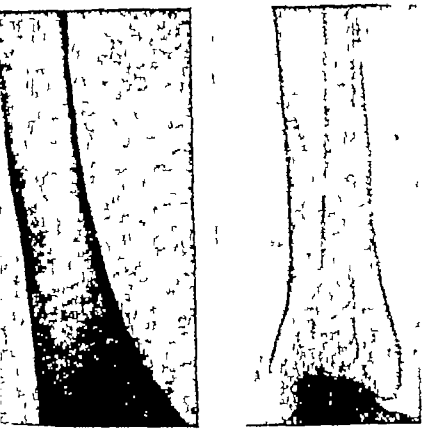

ig. 8 (same patient as fig 7)—X rays of (a) the lower end of the femur and (b) the lower end of the tibia.

have been able to find no modern reference to experiments on the strength of cancellous bone Indeed, the ly publication is that of Ward in 1838 to whose book have already referred He wrote:

> "A cubical inch of cancellous tissue was cut from the ntre of the external condyle of an adult macerated femur d subjected to gradually increasing pressure with the llowing results It sustained four hundredweight without isible alteration; sank a little on one side upon the addition the next half hundredweight and continued to yield upon ery further increase of pressure so that when the weight mounted to 6 cwt., its height was reduced to half an inch his reduction however took place entirely at the expense of e upper portion of the cube; its lower moiety which esented a much closer texture bore the whole pressure of cwt without visible alteration The weight of the cube mitted to this trial was 54 grs. troy It was placed during e experiment in the natural position with its principal res upright The side on which the cube first gave way rresponded to the outer and posterior part of the condyle d its structure was here evidently looser and more fragile an on the side which in the natural position had lain arest to the axis of the bone In Mr Rennie's experiments on e strength of woods a cubic inch of solid elm was crushed y 1284 lbs avoirdupois—about $2^1/_2$ times the weight beneath hich the cube of reticular tissue began to yield The com arison may assist the reader in forming a just estimate of the trength of the reticular tissue

I have performed some similar xperiments with the assistance f Dr J D Todd of the School f Engineering at Oxford which s equipped with appliances for sting the strength of materials riefly we found that lumbar entra from healthy subjects ithstood a pressure of 0 61–87 ton (1300–1950 lb) before ollapsing. The area of a entrum is about 2 2 sq in hich gives a strength of about 900 lb per sq in as against he 500 lb found by Ward. he difference was that his pecimen was an isolated cube f cancellous bone whereas ours ere whole centra which have thin layer of compact bone around the outside and are presumably designed specially to withstand the kind of pressure that we applied

As well as the strength of 900 lb per sq in normal centra show surprising resilience even after fracture by compression When the centrum has collapsed, if pressure be increased, the deformity becomes greater until the bone is perhaps only $^1/_4$ in thick and squashed outwards till its diameter is $2^1/_2$–3 in As soon as the pressure is released, the centrum resumes its normal shape and is sufficiently strong to resist deformity by manual pressure

Osteoporotic vertebræ are easily crushed, sometimes by trauma and sometimes spontaneously or at least by the application of little more force than the weight of the upper part of the patient's body or the slight stresses caused by the muscular movements of an old person. Centra from old or osteoporotic subjects withstand a pressure of 300 lb per sq in or less, which may seem a large figure in comparison with the normal In real life, fractures in bones are seldom produced by static forces but usually by relatively small forces applied dynamically Work by Evans Lissner and Pedersen (1948) has shown that a force of only 16 inch pounds, applied dynamically to the femur can produce deformation patterns similar to those of forces of 400–700 pounds applied statically Many forms of athletics and games must produce great stresses on the skeleton but in them fractures are relatively rare because in controlled movements the muscles are used to support the skeleton. On the other hand an unexpected fall on to the outstretched hand may produce a Colles fracture with surprisingly little violence Similarly patients with osteoporosis may fracture several vertebræ from minor but sudden trauma

Diagnosis

As I have said before osteoporosis is strictly speaking a histological diagnosis and can be made with certainty only by the morbid histologist but there are clinical features and X ray changes sufficiently well defined to justify the diagnosis at the bedside and it is an important diagnosis, because the condition is often treatable (fig 9)

In a patient over 60 years of age any pains in the trunk or legs for which there is no obvious explanation should raise in the physician's mind the possibility of osteoporosis. If the patient is a woman the chances of this being the cause are six times greater than if he is a man If there is a history of loss of height the odds in favour of the diagnosis are further increased In women special inquiry should be made about the menstrual history, the date of the menopause, and any gynæcological operations especially to ascertain whether the ovaries have been removed Questions about diet and physical activity may provide suggestive information

On examination loss of height as shown by measurement evidence of shortening of the axial skeleton a rounded kyphosis, a transverse infolding of the skin

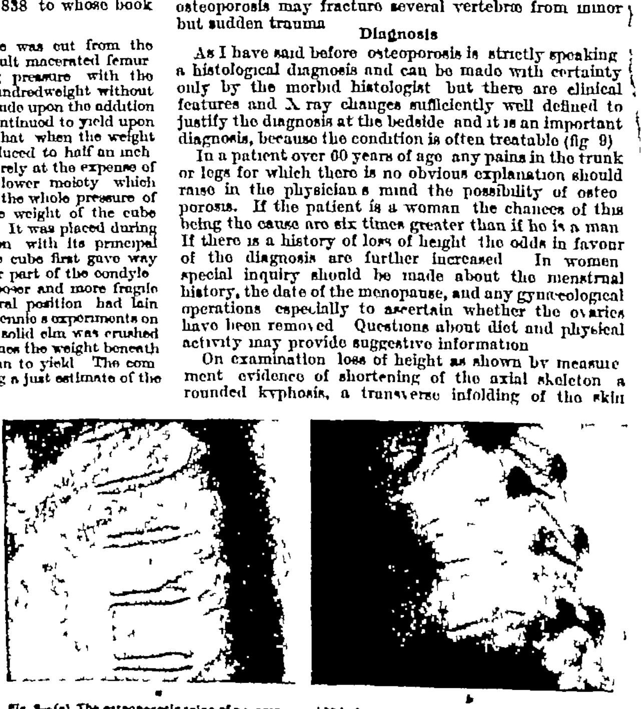

Fig 9—(a) The osteoporotic spine of a woman aged 52 before treatment. (b) The same area from the same patient (then aged 56) after 4 years treatment with calcium and vitamin D This has had no effect on the osteoporosis which has progressed and caused compression fractures

across the upper abdomen, and approximation of the lowest ribs to the pelvis are important signs The patient tends to look older than her stated age, with a lax wrinkled skin Evidence of other disease will be lacking, although the thoracic deformities make the patients unduly liable to chest infections The urine should, of course, be tested for Bence Jones protein, which strongly suggests myelomatosis *but is occasionally* found in other generalised bone diseases Sulkowitch's reagent for the quantitative estimation of calcium in the urine provides a rough screening test for the excessive calciuria of hyperparathyroidism Radiography *of the* spine and pelvis will usually reveal the characteristic changes of osteoporosis, with or without fractures If there is doubt, an X ray film of the skull (which is never affected) and some of the long bones (which are rarely affected except in very advanced cases) should provide valuable negative evidence The presence of a pseudo-fracture at once raises the question of osteomalacia, in this country usually a sequel to steatorrhœa

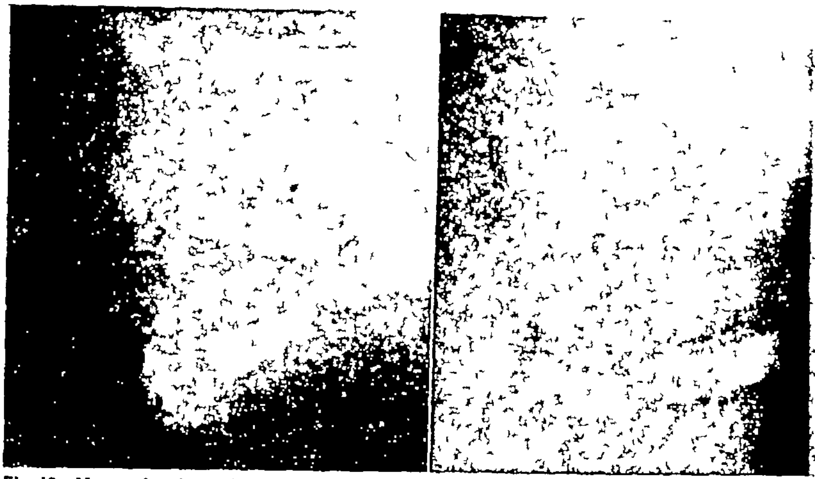

Fig 10—X rays showing radiographic improvement in osteoporosis after 2½ years hormonal therap

In osteoporosis the serum calcium and phosphorus and alkaline phosphatase are within normal limits The average total plasma-proteins are in the lower normal range and the average plasma-albumin just below the lower limit of normal Basically, *the diagnosis is made* by the exclusion of other bone diseases Bone biopsy from the iliac crest or from the dorsal spine of a lumbar vertebra is a practicable investigation (Vogt 1949, Vogt and Tonsager 1949) Lastly, it is sometimes justifiable to try a therapeutic test

Diagnostic traps are to be found in the *other diseases* that produce osteoporosis as a secondary effect Cushing's disease, acromegaly, and thyrotoxicosis usually present characteristic features which should not give rise to serious difficulties More subtle and deceptive are the osteoporotic changes of myeloma, hyperparathyroidism, the osteolytic type of Paget's disease, and so called idiopathic osteoporosis The last is a rare and puzzling variety of osteoporosis occurring in young subjects of either sex, without demonstrable endocrine defect and unresponsive to hormonal treatment

Treatment

The diagnosis of senile or postmenopausal osteoporosis made, the essentials of treatment are firstly to get the patient out of bed, if only to sit up in a chair, at the earliest possible moment Secondly, if the pains are severe, a light spinal jacket will give physical and moral support Thirdly, a high protein diet and a pint of milk a day will ensure an adequate supply of the materials from which bone is formed Last, but not least, is the hormonal treatment Opinion differs on the details, but there can be no doubt that the patient needs some preparation of male sex hormone, such as testosterone propionate 10–20 mg daily by injection, or methyl testosterone 30 mg daily by mouth Androstenediol is said to have the anabolic actions without undue masculinising effect The patient also needs a female sex hormone, such as œstradiol benzoate or dipropionate 2 mg daily by injection, or an oral preparation such as dienœstrol 1 mg daily, or æthinylœstradiol 0 1 mg daily There are satisfactory proprietary preparations containing appropriate mixtures of male and female sex hormones *Large doses are not required,* and osteoporosis is one [illegible] diseases where twice the dose of medicine *does not produce twice as good an effect, but the revers* Indeed, large doses of œstrogens inhibit bone growth Intermittent treatment will tend to prevent unpleasant side effects, and a régime of four weeks' treatment and two weeks off is often recommended Treatment should be continued for a long period, probably for not less than two years *In successful cases, the trunk pains will b* greatly improved in two weeks, and in severe bedridd cases in two months The effects of treatment are usually more pronounced in patients who have underg surgical removal of the ovaries than in those who ha had the normal gradual diminution of œstrogen activit by age

There are many cases on record of patients wi postmenopausal osteoporosis, and indeed with sen osteoporosis, who have shown great subjective improv ment on endocrine therapy and a corresponding improv ment in function, but very few cases have been report where *the X-ray appearances of the bone have be* improved Nearly all writers on the subject comment this curious fact

Cases of X ray improvement have been reported Albright and Reifenstein (1948), by Sherman (19 by Snapper (1952), and by Polishuk and Kleinh (1952), and I have seen two myself (fig 10) A poss explanation is that X-ray changes for the better are dom seen before two years' treatment and many patie are not followed up for so long a period Reifenste and Albright (1947) estimated that osteoporotic patien receiving appropriate endocrine therapy retain abo 200 mg of calcium daily If we assume that a sever osteoporotic patient has lost half the bone substance his skeleton, which is not an excessive estimate, at th rate of replacement it would take seven or eight years restore the bones to normal

Voltaire's gibe that "a physician is one who po drugs of which he knows little into a body *of which* knows less" is unfortunately still true and applies ev to endocrinology In the treatment of osteoporo chief unpleasant side effects arise from the masculinis effects of androgen therapy, which are of course m noticeable in women, who provide the majority *of t* patients *There may be coarsening of the skin,* ac hirsutism, deepening of the voice, and occasionally unseemly increase in libido Oedema of the ankles m occur from retention of electrolytes These effects seldom serious, but they are distressing to the pati They can best be prevented firstly by the use of sm *doses, secondly by intermittent treatment,* and thirdly the opposing action of œstrogens

The commonest undesired effect of œstrogen ther is uterine bleeding in women past the menopause.

possible carcinogenic effects of male and female sex hormones are a very remote danger because the doses are small and the drugs are merely replacing something which the patient is lacking

Prevalence

How common is osteoporosis? Omitting local forms such as osteoporosis of the pubic bone in prostatic disease Sudeck's atrophy osteoporosis cranii circumscripta, and the like over 800 cases have been reported (references in bibliography marked with an asterisk) The proportion of female to male patients was 6 to 1 and this is a significant ratio to which I shall refer later

Albright has described osteoporosis as the commonest bone disease likely to be encountered by the physician Priority of place must I think, be disputed by Paget's disease but there can be no doubt that both are extremely common It is interesting therefore to see how osteoporosis is dealt with in the standard British textbooks of medicine for students The following table shows the number of lines devoted to the subject in ten such textbooks

Textbook	*Date*	*Osteoporosis of any type*	*Postmenopausal osteoporosis*
A	1950	0	0
B	1950	4	0
C	1951	6	6
D	1952	0	0
E	1952	0	0
F	1953	4	4
G	1953	0	0
H	1953	0	0
I	1953	40	0
J	1954	8	0
	Total	62	10

A Personal Series

My own experience is similar to that of all those who have interested themselves in this condition The adult inpatient records of the Radcliffe Infirmary over the past fifteen years show that, of the common medical osteopathies there have been 110 patients with Paget's disease, 36 with spinal osteoporosis of one sort or another and 6 with osteomalacia (all from steatorrhœa) I have also found some osteoporotic subjects among the outpatients, and with some private patients have brought the total to 50

Of these 50 patients 43 were women and 7 men 30 were over the age of 65 and the osteoporosis was presumably senile in origin 20 were under 65 14 women and 6 men, and in the women the condition was presumably postmenopausal (fig 11)

The results of routine laboratory investigations were

	Number of observations	*Mean*
Serum-calcium	37	9 5 mg per 100 ml
Plasma-phosphorus	32	4 0 mg per 100 ml.
Plasma phosphatase	31	9 6 units
Plasma-protein	19	6 7 g per 100 ml.
Plasma-albumin	19	3 7 g per 100 ml
Blood-sedimentation rate	26	25 mm. in 1 hour

It will be seen that the serum-calcium plasma phosphorus, and plasma phosphatase are all within normal limits—a diagnostic point of importance The total plasma proteins are within the normal range but the plasma albumin is just below the generally accepted lower limit of normal (4 0 g per 100 ml) The slightly raised blood sedimentation rate is difficult to relate to the bone condition because there are so many other factors which may affect it

Apropos of the low serum-albumin levels Henneman Carter, Forbes and Dempsey (1953) tried the effect of protein administration on 4 patients with osteoporosis. There was no demonstrable effect from oral administration Daily intravenous injections of 50 g of human serum albumin for periods of from nine to thirty days produced a rise in serum albumin and considerable retention of calcium and phosphorus Henneman et al inferred, but could not prove that the treatment was a stimulus to bone formation and that serum albumin might 'actually be the transport form of bone matrix precursor'

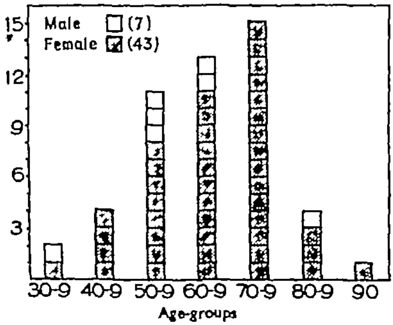

Fig 11—Age-incidence of 50 patients with spinal osteoporosis.

Of my series 37 patients were given hormones—mostly combined œstrogen and androgen therapy—but 5 had œstrogens only and 3 androgens only The follow up was adequate in 27 cases. Of these, 1 patient said that she felt worse but the remainder reported subjective improvement in varying degrees 4 patients were able to discard plaster casts, and 2, from being completely bedridden were able to get up from bed and walk about 16 patients over the age of 65 were treated with endocrine therapy and adequately followed up Of these 15 were obviously greatly improved and 1 was the patient mentioned above who felt worse

Prevention

There is no doubt that age is a common and important factor but not as has often been supposed, the only factor It is probable that a large proportion of persons over the age of 70 have some degree of osteoporosis The fact that at all ages the ratio of women to men is six to one suggests that something other than age is operative and all the evidence points to this being an endocrine factor

It is a matter of some therapeutic importance that patients with so-called senile osteoporosis respond to the appropriate treatment for so-called postmenopausal osteoporosis. The distinction between these two types is probably not only artificial but non-existent and they are really the same disease

As regards prevention there are about 7 million postmenopausal women in England and Wales, not to mention those younger who have had the ovaries removed or irradiated and over 5 million men above the age of 50 Many persons over 60 will not of course, develop osteoporosis other than the gradual and inevitable changes which will occur if they live till 70 or over But a considerable number will sustain compression *fractures* of the spine either spontaneously through extreme osteoporosis or through injuries occurring on top of moderate osteoporosis and some will become bedridden and crippled A number will sustain fractures of the *femoral* neck from trivial injuries

This formidable problem will be met if physicians surgeons and *gynæcologists* have an awareness of the existence of osteoporosis and its implications *and* realise that it is one of the few treatable chronic conditions in elderly *patients and indeed is* probably the only age change in the body that can be reversed

No-one could seriously advocate universal endocrine substitution therapy after the age *of 50* It would be administratively impossible and very costly and would carry hazards There are however some simple preven tive measures worth considering, specially by those responsible for the care of old people It will obviously be wise to encourage some physical activity, or at least to discourage undue inactivity It should not be difficult to arrange an adequate protein, calcium, and phosphorus intake—a pint of milk daily would guarantee 680 mg of calcium It would be simple to record the height of each subject annually, and to inspect the abdomen for the appearance of a transverse fold across the epigastrium Any aches or pains in the trunk for no good reason should at once call for antero posterior and lateral X rays

Patients with osteoporosis, or even patients potentially osteoporotic, should be given cortisone or corticotrophin with great caution, if possible not in large doses or for long periods (Hjorth and Dragsted 1953) In the recorded cases of osteoporosis with fractures occurring during cortisone treatment, the patient has almost always already qualified for osteoporosis by immobilisation or the postmenopausal state (Boland and Headley 1950, Teicher and Nelson 1952, Demartini, Grokoest, and Ragan 1952, Curtiss, Clark, and Herndon 1954)

Summary

I conclude by summarising the points which I consider the real essentials of these lectures

Firstly, the skeleton undergoes slow, steady resorption from all its surfaces, more apparent in cancellous than compact bone

Secondly, this process is counteracted by endocrine factors and the physical stresses and strains of use It is affected to a lesser extent by diet and age

Thirdly, osteoporosis is an extremely common condition

Fourthly, so called senile osteoporosis has an endocrine component which is treatable

It will have been obvious that these lectures have been largely a compilation from the work of others, whose original contributions to the subject I gratefully acknowledge I have received the most generous help from colleagues and friends too numerous to mention, but I must allow myself the pleasure of placing on record my particular indebtedness to Dr Alastair Robb Smith

HIATUS HERNIA

SURGICAL RELIEF OF REFLUX ŒSOPHAGITIS

CHARLES WELLS
M.B Lpool F.R.C.S
PROFESSOR OF SURGERY UNIVERSITY OF LIVERPOOL

J H. JOHNSTON
M.B Belf F.R.C.S F.R.C.S.I
SENIOR SURGICAL REGISTRAR, LIVERPOOL ROYAL INFIRMARY

HIATUS hernia of the sliding type is a very common condition, in which the tissues at the œsophageal hiatus of the diaphragm have relaxed and allow the cardio-œsophageal junction to become retracted into the chest This retraction unfolds the acute angle between the œsophagus and the fundus of the stomach which normally prevents reflux of the gastric contents into the œsophagus (fig 1*a*) The hernial sac may occasionally be quite large but usually it is very small—indeed scarcely more than a potential sac which can be invaginated with the finger for an inch or so (fig 1*b*) The characteristic symptoms are caused by reflux and their severity does not depend on the size of the hernia

Ætiology

The *ætiology* is not fully understood, but advancing years obesity and increased intra-abdominal pressure as in pregnancy all play a part Since the pressure within the abdomen is positive and the pressure in the chest negative it is perhaps not surprising that this hernia should appear from time to time, and its more frequent recognition in recent years may be related to dietetic and weight changes in the population Gall-stones are often found in association with hiatus hernia and may arise from common causes Hyperchlorhydria with duodenal ulceration is also a common concomitant and it is possible that in both cholelithiasis and ulcer a vagal reflex may cause muscular contractions of the œsophagus and so lead to retraction of the cardia More probably, however in duodenal ulcer it is the hyperchlorhydria which aggravates the effects of associated but unrelated reflux

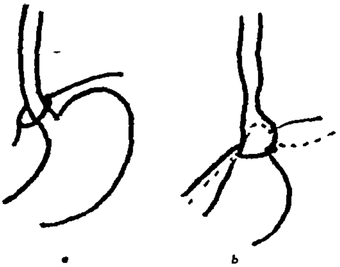

Fig 1—*a* Normal angle between œsophagus and stomach tends to obstruct gastro-œsophageal reflux; *b* retraction of cardia into thorax is followed by small sac of peritoneum (unfolding of cardia facilitates gastro-œsophageal reflux)

Symptoms and Diagnosis

The symptoms which suggest retracted cardia are heartburn (retrosternal burning pain) and acid regurgitation into the throat especially on lying down or on stooping Later there may be painful dysphagia from œsophagitis or ulceration or obstructive dysphagia from spasm or stricture The stricture may be annular from the healing of superficial lesions or may be due to dense fibrosis of the œsophagus and peri-œsophageal structures causing organic fixed shortening Secondary anæmia from steady slight bleeding is not uncommon, and sharp hæmorrhage may rarely occur One of our patients had a fatal hæmorrhage from perforation into the aorta, and in another who recovered a peri-œsophageal abscess was caused by a penetrating ulcer These severe complications are quite unusual and are more likely to arise from ulceration at the level of the hiatus in the gastric pouch of a large hernia than from the commoner inflammation or ulceration of the œsophagus itself caused by reflux. The pain of a penetrating ulcer is experienced at the level of the lower ribs, especially towards the back. It may be excited by swallowing

Investigations to confirm and assess the condition comprise radiography a search for occult blood, the estimation of gastric acidity the exclusion of other disorders (e.g duodenal ulcer and gall-stones) and œsophagoscopy The endoscopy may reveal superficial ulceration spasm or stricture formation, redness and œdema or simply an abnormal regurgitation of gastric

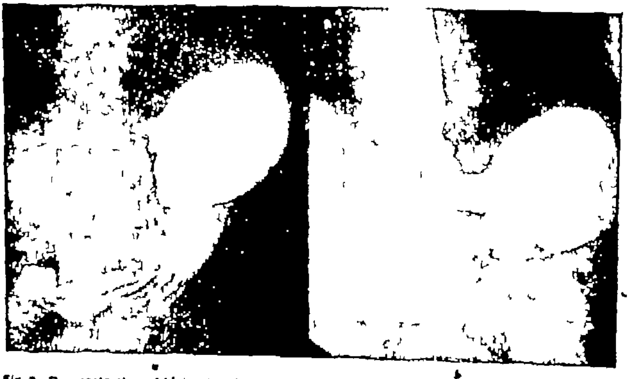

Fig 2—Demonstration of hiatus hernia: *a* with patient in head-down position diaphragm holds back gastric contents and no herniation is visible; *b* a further swallow of barium reveals herniation.

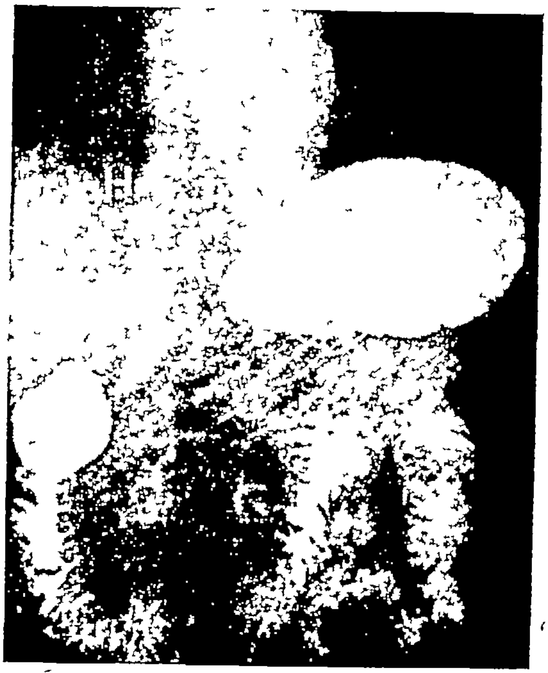

Fig 3—Typical small hiatus hernia.

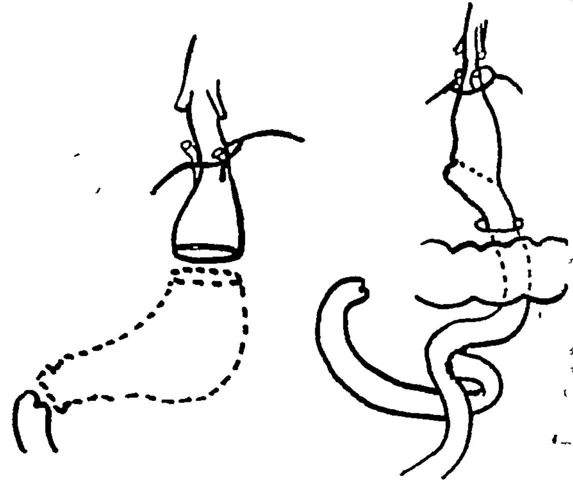

Fig 4—Scheme of operation described in text.

contents Gastric mucosa is seen sooner than is normal in some cases but not in all, since the instrument will displace the cardia downwards in the early and fully mobile case

A normal bismuth series may show retraction and incompetence of the cardia, or this may be demonstrable only with a special technique in which, after the meal, the patient, having been put in the head down position to show the fundus, is given a further bolus to swallow (fig 2) Even with the greatest care it may be difficult to distinguish with certainty between a small hiatus hernia (fig 3) and the physiological intermittent dilatation of the œsophagus, known as an epiphrenic ampulla, which is not associated with regurgitation Observation under the X-ray screen is of the greatest value and most instructive

Treatment

Non operative treatment gives a variable amount of relief Weight should be reduced, and food should not be taken for some hours before retiring, when antacids should be given as a nightcap The patient should be instructed to sleep propped well up with several pillows

Surgical Treatment — Conventional surgical treatment for those who do not get relief from non-operative measures is ordinarily directed to correction of the deformity By a thoracic approach the lower end of the œsophagus is drawn down to below the diaphragm and fixed there with sutures Reconstitution of the normal œsophago gastric angle is the essential and effective step Unfortunately most workers report a high incidence of recurrence after this operation, and in our own hands the recurrence rate has been so high that we no longer use this method

An alternative operation which we practise and advocate is based on a different principle We accept the incompetent cardia but seek to prevent regurgitation by securing rapid emptying of the stomach We also produce achlorhydria and divert the bile and pancreatic stream so that such regurgitation as may persist does no harm These desiderata are achieved by vagotomy, partial gastrectomy, and re anastomosis by the Roux-Y method (fig 4) The approach is from the abdomen

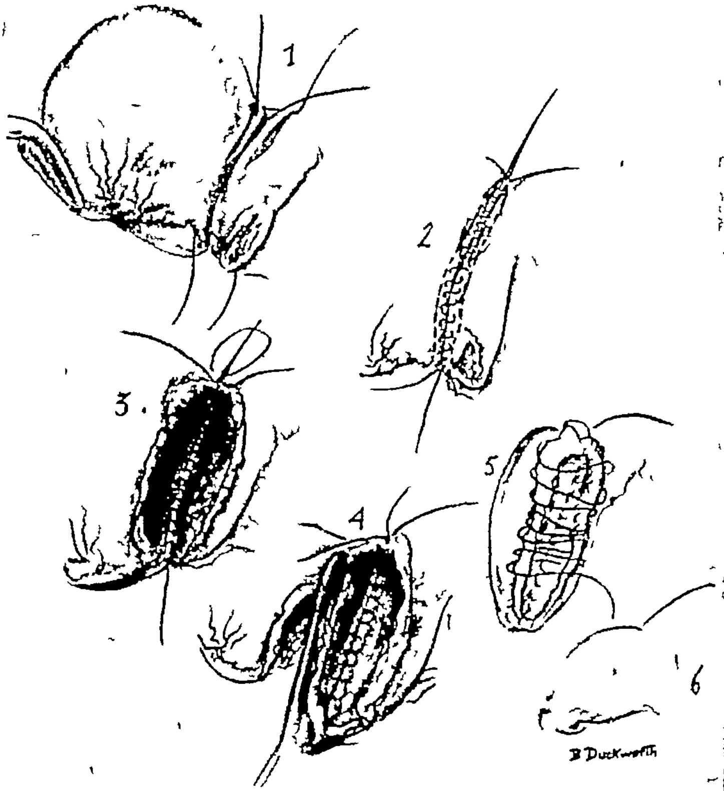

Fig 5—Gastrojejunal anastomosis : 1 start of edge-to-edge suturing at point of exit from stoma near greater curve 2 continuation of this suture line as conventional seromuscular suture and indication, by interrupted lines, of incisions into stomach and jejunum 3 posterior suture line completed and corner at open end of jejunum trimmed away; 4 distal part of stomach being cut away , 5 anterior suture line taking mucosa alone near greater curve and all coats elsewhere (cf fig 6) 6 suture-line completed

und consequently enables any associated abnormality o be given appropriate attention

The diagnosis is confirmed by palpation of the hiatus, hrough which a pouch of peritoneum can be palpated or xpelled by the examining finger If the hernia can still be educed which is usual, the left lobe of the liver is mobilised he peritoneum incised around the hiatus, and the œsophagus freed and drawn down into the abdomen for an inch or two Vagotomy is then carried out in the usual way If a completely satisfactory denervation is not achieved this fact should be carefully noted, so that in the event of pain recurring a transthoracic vagotomy may be advised If the patient is obese or if the œsophagus cannot be pulled down, vagotomy by the transthoracic approach becomes obligatory

The gastrectomy follows the usual lines. We like to conserve the gastro-epiploic arch. In hiatus hernia we do not always divide the left gastric vessel near its origin; alternatively we divide the descending branch on the lesser curve About two-thirds of the stomach is removed and the duodenum is carefully closed as usual.

The upper jejunum is then displayed and a point is selected a few inches beyond the flexure for its division Nutrient vessels are sacrificed and arcades preserved in such a way that the jejunum distal to the cut can be drawn up through the mesocolon and anastomosed to the stump of the stomach without tension The opening at the cut end of the jejunum is extended by an incision along its antimesenteric border and the resultant corners are trimmed away The anastomosis is made with great care at the point of exit at the greater curve since easy emptying of the stomach remnant is essential to success. Sometimes at this point in the anastomosis we use the edge-to-edge technique illustrated in fig 6 The mesocolon is finally fixed to the stomach proximal to and around the stoma.

The anastomosis in Y is completed about twelve inches below the stoma by bringing the biliary loop underneath and round to the left side of the vertical limb To avoid any narrowing of the jejunum carrying the food-stream (the vertical limb) the suturing is done with meticulous care in a special manner As illustrated (fig 6) the seromuscular coats are joined edge to edge with a continuous catgut stitch the loops of which are placed as delicately and as close together as possible The posterior mucosal layer is oversewn, and the stitches almost encroach on the first layer The anterior mucosal layer is made with a Connell stitch almost encroaching on the cut seromuscular coats and these are finally sutured together as in the first layer This close suturing controls hæmorrhage whilst the use of the extreme edges of the structures avoids constriction in a remarkable way

During the anastomosis it is impossible to control bleeding from the jejunal ends with the ordinary bowel clamps, but we have found that Crile's vessel-clamps on the mesenteries are excellent.

Discussion

It is twenty years since one of us performed his first gastrectomy for hiatus hernia. There was a large fixed hernia with a penetrating ulcer of the stomach at the level of the hiatus Polya gastrectomy below the level of the ulcer (Wells 1933) was undertaken as a first stage procedure It gave complete relief and no further treatment was required More recently however, we have been disappointed with the results of both the Polya gastrectomy and the Steinberg (1940) modification in the presence of retracted cardia because of the persistent

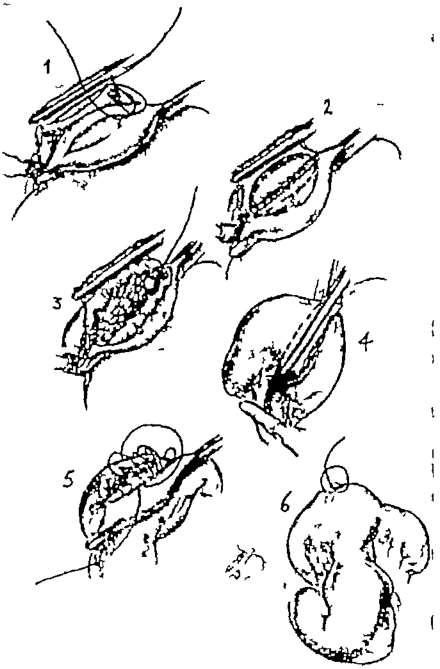

Fig 6—End-to-side jejunal anastomosis by edge-to-edge technique; 1 seromuscular coats joined; 2, incision through mucosa indicated; 3 posterior mucosal layer completed; 4 final seromuscular incision at end of afferent loop indicated; 5 anterior mucosal closure with Connell's stitch; 6 edge-to-edge seromuscular suture completed.

HIATUS HERNIA FORMER OPERATIONS, ASSOCIATED DISORDERS, AND PRESENT SYMPTOMS

Patient no	Sex	Age (yr)	Former operations	Associated abdominal disorders	Duration of follow up (mos)	Present symptoms	Weight

vomiting of bile In patients 9 and 10, who had each undergone Steinberg gastrectomy, the symptoms of œsophagitis persisted, and there was profuse regurgitation of bile on recumbency or stooping Conversion of the anastomosis to the Roux type, without disturbing the original gastrojejunal stoma, and vagotomy, have produced, in patient 9, complete relief of dyspepsia and gain in weight Patient 10 had also complained of palpitations after food, following the gastrectomy This symptom has persisted to a lesser degree after the conversion operation and, in addition, the patient has occasional reflux of clear fluid into the mouth

The cases are summarised in the accompanying table The predominant complaints in the three patients with concomitant duodenal ulcer were related to the incompetent cardia rather than the ulcer The history of the remainder conformed to a common type, and the following is typical

Case 6—A man, aged 74, was admitted to the Liverpool Royal Infirmary in August, 1953, with four years' history of burning epigastric and retrosternal pain radiating to the neck and regurgitation of acid fluid into the mouth on lying down He was often wakened at night by a choking sensation due to fluid in the throat, and there were pain and difficulty in swallowing and loss of weight Probable œsophageal carcinoma had been diagnosed in another hospital

On admission clinical examination was negative Radiography showed slight spasm in the lower œsophagus and, in the Trendelenburg position, revealed a sliding hiatus hernia with incompetence of the cardia A fractional test meal showed hyperchlorhydria Retraction of the cardia and œsophagitis were confirmed at œsophagoscopy, but, in view of the patient's age, medical treatment with diet, alkalis, and an inclined sleeping posture was advised

Progress—Seven months later the patient was readmitted with no improvement in his symptoms and requested an operation Ten months after operation he is free from dyspepsia and has returned to his work as a hairdresser

All our patients obtained complete relief from their main symptoms by operation Subsequent fractional test-meal or 'Diagnex' tests have shown achlorhydria, which suggests that vagotomy and two-thirds gastrectomy do in fact protect the Roux anastomosis from the danger of stomal and jejunal ulceration which formerly led to its abandonment in the treatment of peptic ulcer In case 8, because of difficulty in exposure, vagotomy was not performed with the gastrectomy The patient remained well until three months later, when there was a recurrence of heartburn and pain on swallowing, which was relieved by alkalis Eupepsia has been restored by transthoracic vagotomy

It was feared that the entrance of bile and pancreatic juices into the alimentary tract at a distance from the stomach might interfere with normal digestion and absorption and lead to a deficiency type of post gastrectomy syndrome, but some of the patients have in fact gained weight and in none has there been a significant loss There has been no evidence of vitamin deficiency It is too soon to be sure whether or not microcytic iron-deficiency anæmia will develop, but it is, if necessary, easily corrected (Wells and Welbourn 1951)

Summary and Conclusions

Attention is drawn to the frequency of retracted cardia and gastro œsophageal reflux as a cause of dyspepsia

The diagnosis of the condition is outlined and, for its treatment, an operation which is new in this context is described It consists in vagotomy, partial gastrectomy, and re-anastomosis by the Roux-Y method

Satisfactory early results in twelve consecutive cases are summarised

THE MANAGEMENT OF CHILDREN UNDERGOING TONSILLECTOMY

PREMEDICATION WITH METHYLPENTYNOL

F R GUSTERSON

B Sc, M B Lond, F.F.A R C S

ANÆSTHETIST, WORTHING GROUP OF HOSPITALS, SUSSEX

It is estimated that every week, in Great Britain alone 1500 children undergo tonsillectomy In most cases this will be their first experience of hospital, and the responsibility for seeing that it does not cause emotional harm which may affect the child's whole life, rests largely on the anæsthetist Though much has already been written on the subject[6 14 16 17 20] it is one which should be continually reviewed in the light of new methods

Admission to Hospital

With a child of under 5 years of age, the important question is whether he has already learnt to adjust to separation from his mother by the normal process of going to school If this has not yet happened, no amount of sedation with drugs will save him from being mentally hurt by this forced separation So important did the late Sir James Spence feel this to be that he devoted much of his energies to establishing a hospital unit in which mothers had to remain in hospital with their babies It would be difficult to insist on this for tonsil cases, but much can be done even in routine hospital work to minimise the emotional trauma

So far as is practicable, each block of admissions should be of a similar age group The constant crying of the 2-year-old can be very upsetting to a 10 year-old, in addition the older boy resents being in hosp "with kids"

The mothers of all children of age groups usually admitted to children's wards should not only bring the child into hospital but should give him his first bath put on his night clothes, which could, with advantage be the child's own Many children feel more secure their own clothes The time of admission is important and should never be in the morning unless this absolutely unavoidable To put a young child to in the morning is synonymous with punishment first meal in hospital should be given by the mother aided by the nurse who will look after the child. raises a very important point The number of persons dealing with the child should be as small as possible ideally one nurse only, who will thus become temporary mother substitute

While the mother is still present, the child should meet as many as possible of the people whom he will next day, including theatre porters All these persons should be chosen for their ability to handle children there is a type of hospital porter who would frighten child out of its wits If not already done at home, would be a good time to tell the child exactly what happen the following day

One point which should be emphasised is the importance of the child's bringing into hospital some favourite toy, however shabby This is brought out very well Robertson's[28] film, in which the toy is a piece of well chewed blanket The toy will be returned the child, for the old idea of infection being transmitted in this way is no longer held This toy will naturally accompany the child to the operating theatre, which the end of a morning's list may thus look rather like scene from a Walt Disney cartoon The toy must be in the cot when the child wakes up

On the Way to the Operating-theatre

If the child is not asleep when his time comes to to the theatre he should never be made to lie down the trolley To lie flat on the back while being wheeled along corridors is very frightening The operating should be carefully timed, even when this means some inconvenience All operations on children should be done as early as possible in the day A child will tolerate the absence of his breakfast, but the absence of dinner as well, particularly if other children in the ward are having theirs, is really putting too great a strain on his control

Two more simple points are worthy of mention here The first is the old fashioned practice of making the child wear a mackintosh cap and bib for tonsillectomy With modern surgical techniques this surely is no longer necessary, and the children are much happier without them.

The other point is the wearing of face masks by the theatre staff It is most important that every person handling a child on his way to the theatre and in the anæsthetic room should have the face fully exposed Half masked faces are extremely frightening to children and it is a great help to the child to be able to recognise his ward nurse

Sedation

Many anæsthetists feel that to avoid any possible emotional upset all children of whatever age should be completely asleep before leaving the ward for the theatre This would in many ways be ideal provided that the perfect drug or combination of drugs could be found Even so the remarks in the foregoing paragraphs still apply to the time before and after the child has its actual operation and I suggest that however perfect the 'asleep in the ward' technique is some case will occur where sedation is incomplete Many think, although it is difficult to prove that in the resulting partially disorientated state a child is even more impressionable than when fully conscious This certainly applies to adults as many will remember from the early days of the use of barbiturates by mouth for premedication

Innumerable methods have already been used to ensure that every child is fully asleep before leaving the ward, and each has its enthusiastic advocates Having tried them all I have given them up one by one Personally, I feel that the rectal administration of drugs to children should be avoided except when absolutely necessary Children may not like an injection or a nasty medicine but that is an affair of the moment that a child can have explained to it. Not so with rectal interference, and the very young child is also psychologically sensitive about its rectum Hence while admitting the safety of rectal paraldehyde and the smoothness of rectal thiopentone I cannot agree that they should be used as a routine practice Furthermore I did find when using rectal paraldehyde in children some years ago that many had postoperative pyrexia and for several days were not fit to return home The disadvantages of any barbiturate (see below) are also applicable to rectal thiopentone

I have also used morphine for premedication either as morphine and atropine or as 'Omnopon' and hyoscine, using the dosage schedules advocated by various workers[8 16] I was immediately confronted with an increase in postoperative vomiting and complaints from the ward sister that quite a number of children were dangerously depressed on return to the ward, and that great difficulty was experienced in keeping their airways clear The dosage of these extremely potent drugs is small and minute errors can have serious consequences.

At present the drugs most popular for premedication are pentobarbitone ('Nembutal') and quinalbarbitone ('Seconal') Though undoubtedly satisfactory in many cases these have very grave disadvantages I have found very little to choose between them and I wonder whether it would be possible to differentiate between these two drugs by purely clinical assessment The following remarks about pentobarbitone therefore apply equally to quinalbarbitone

Barbiturates

In the first paper on pentobarbitone in this country Magill[31] wrote

> ' As with other barbiturates the variable reaction of individuals to nembutal renders the dosage by mouth and by rectum difficult to determine beforehand This is especially noticeable in children. In general, it may be stated that children are more resistant than adults and in children the variation has little to do with age or development For example, one well-developed child age 7 was fast asleep after the administration of grs. $1^1/_2$, while another child aged 6 and of small physique was quiescent but not asleep after grs. 3 had been given.

He further said that ' Irrespective of the dose or method of administration, a variable degree of restlessness was noted during the immediate post-operative period in 13 patients Five were children and their condition was controlled by potassium bromide

Waddy[30] confirmed the postoperative restlessness and in subsequent articles on these drugs the same two drawbacks of uncertainty of effect and postoperative restlessness have been mentioned[4 6 12 18 29] This still applies even if in a lesser degree, when the drug is given rectally

Postoperative restlessness is a more serious problem than this uncertainty of dosage and can be so great that a single nurse can hardly control the child A wardful of such children is in a real state of pandemonium, which can be reduced to a manageable degree only by giving morphine or one of its derivatives.

From the state of uncontrolled restlessness it is so easy to pass to that of an uncontrolled airway serious enough after any operation but liable to be extremely dangerous after an operation on tonsils and adenoids By whichever method the operation is done, blood is apt to accumulate in the upper respiratory passages Again even if the airway is not obstructed there is the very real risk that blood and mucus will be inhaled into the lungs during the state of respiratory depression which may follow the giving of morphine after a barbiturate

I was delighted to see attention drawn to this by Fraser[8] and Middleton Price[24] The situation is often made worse by ordering further morphine to control the hæmorrhage I recently had experience of such a case and at necropsy the lungs were full of inhaled blood which had without doubt been the cause of death I have indirect knowledge of other such cases which could usefully be made known and discussed Even if this complication occurs only in 1 case in 2000 it is too high a price to pay for the doubtful advantage of the child's being asleep before leaving the ward

A much less important difficulty with these barbiturate preparations is that of administration They all have an extremely unpleasant and long lasting taste and hence are supplied in capsules Nurses have developed many ingenious ways of administering these but often several mouthfuls of water are given When there has been some emotional upset during the attempt to swallow the capsules this may not be absorbed from the stomach with the result that the child vomits during the induction of anæsthesia Also in such cases the drug has not usually been absorbed and the child is still awake, thereby losing the whole purpose of this method. The drug may become absorbed later, another factor contributing to postoperative respiratory depression With these drawbacks in mind I had for some time relied on atropine alone for premedication induction usually being by intravenous thiopentone—a technique used by many others But in spite of the most careful handling about 20% of the children were obviously much upset by the visit to the theatre and yet another injection

Methylpentynol

The advent of methylpentynol therefore seemed to offer a via media between the dangers of a barbiturate and the disadvantages of no preoperative sedation All the early reports [2 7 10 11 13 22 23 25 26] of its use as a hypnotic emphasise the absence of side effects, especially respiratory depression and alteration of blood-pressure or pulse Methylpentynol was reported as having a specific effect in allaying fear and apprehension, even in doses where actual sleep was not obtained It is available commercially as a flavoured coloured elixir of 'Oblivon' (British Schering) containing 250 mg of methylpentynol per teaspoonful The flavour cannot be described as pleasant—it vaguely suggests paraldehyde—but in actual practice children very rarely complain about it

As soon as this investigation was planned, it became necessary to find some method of recording the children's reactions which would be impersonal and in no way subject to bias or prejudice It was decided to follow the work of Robertson of the Tavistock Clinic and make a film record showing children's reactions with different forms of premedication Cases were chosen at random by the camera operator from routine operating-lists This film is now available and demonstrates better than words the reactions of the children In nearly every case the child looks happy not only on going up to the theatre but also—perhaps more important still—on waking up in the ward afterwards

We soon found that in many cases the doses recommended by the makers had little effect We now give two teaspoonfuls for children aged 2–4 years, three teaspoonfuls for children of 4–8 (varying slightly with the build or temperament of the child), and four teaspoonfuls for children of 8–10 The methylpentynol should be given an hour before the anæsthetic, and the atropine can then be given half an hour later, when the child is much less upset by having an injection With these larger doses the children nearly all arrived in the anæsthetic room quiet and apparently unperturbed, some actually asleep though easily aroused Brown and Ellis[5] confirm the great safety margin of methylpentynol

In nearly every case anæsthesia was induced with a "sleep dose" of intravenous thiopentone This is a safe and easy procedure in a quiet and peaceful child, but the possibility of an intra-arterial injection has always to be borne in mind Attention was first drawn to this by Macintosh and Heyworth,[19] but there should be no difficulty in these cases, because the child will cry at once if the artery is touched If the child cries at all, the position of the needle must be checked, and, if there is any doubt, the injection is not continued Instead it is quite easy to induce anæsthesia with nitrous oxide without distress to the child

With this method no difficulty from vomiting in induction (Rendell[27]) has been observed, nor has there been any increase in postoperative vomiting I think the difference in my series (which now extends to more than 500 cases) is due to the fact that the methyl pentynol has been given early enough to be absorbed from the stomach

The ward immediately commented on the greatly decreased degree of postoperative restlessness in children premedicated with methylpentynol Children given no postoperative 'Nepenthe' were carefully watched and showed little restlessness, what little there was ceased in a few minutes No special control was required Absence of respiratory depression was quite obvious, and the children could keep their own airways clear even if they rolled over on to their backs This was equally true after an injection of nepenthe minim 1 per year of age With such a dose the children all remained peacefully asleep, and it is now our routine to give this injection as soon as the child shows signs of returning to consciousness

Before deciding on the value of this new method of preoperative sedation it was necessary to study it from the child's point of view A survey of these children

GENERAL COMMENTS

was therefore undertaken along the lines of th Albany Research Project[1] An experienced psychiat social worker was employed who also had a knowled of general hospital routine and an understanding children She was given the admission lists from th record department of the hospital and chose 100 cases random I did not know which cases she had visited, she did not know what anæsthetic technique had be used in any particular case Thus any possible bias opinion was eliminated. The children chosen w visited in their homes about a week before admission again several days after their return home Many of th children were visited several times in a period up to th weeks after their discharge from hospital

Several interesting factors emerged from this inve gation The first was the great advantage of a vi "by somebody from the hospital" The child's moth and the child had the whole episode explained in sim non-technical language It would be an excellent way reducing fear of hospital if this could be done in eve case, if not, perhaps a simple letter explaining th routine in hospital could be sent with the admiss note

The questionnaire is shown in the accompany figure This is quite a simple form because it was n considered advisable to make each child into a psych logical study, but all the necessary facts are includ in it

The numbers of children receiving pentobarbitone a methylpentynol were almost equal This was qu fortuitous At once it was evident that the proport of children disliking their hospital experience was equ in each case (see table)

REACTION TO STAY IN HOSPITAL

—	Received pentobarbitone	Received methylpent
No of children	51	49
Reaction favourable	40	39
Reaction unfavourable	11	10

ie "unfavourable reactors' varied in their com aints Most mentioned specifically a dislike of pricks,' while others merely mentioned that they did t like having to sleep in a room with the lights on or at they did not like the food

The number of children showing any real emotional pset was quite small in each series. Of those receiving ntobarbitone 3 showed increase of nightmares and of ose receiving methylpentynol 5 showed emotional upset ich as crying at night, and disinclination to return to hool Children showing this emotional upset were all nder 6 years old

It is therefore fair to deduce from this admittedly mall survey that there is no specific advantage from the hild's point of view in heavy preoperative sedation that btained with methylpentynol being adequate to prevent ny appreciable psychological trauma

The number of children mentioning an objection to the njection was considerable, and equal in each series This ed me to think of some method of avoiding the injection f atropine At first the atropine was dissolved in a ittle water in doses of gr $^1/_{100}$–$^1/_{50}$ according to age, nd this solution was added to the elixir This had a efinitely adverse effect on the not too pleasant taste of he elixir and in addition the children were not dry nough for comfort during induction or operation At he same time it was thought that the sedation obtained as not so good, but since secretions were not adequately ontrolled only a few cases were investigated

Hyoscine was next used in the same way in doses of r $^1/_{150}$–$^1/_{75}$ This did not affect the taste of the lixir and in every case the drying effect was satis actory In addition there was a much greater sedative ffect. Nearly every child arrived in the anaesthetic oom actually asleep, although easily aroused. In the ostoperative stage there was no restlessness and even nepenthe was given the children were quite easily roused. The ward nurses in fact commented that the hildren seemed to sleep naturally for the rest of the day ter returning to the ward although they could be oused quite easily and given a drink after which they uietly settled down and returned to sleep This modifi ation has not yet been used in many cases but so far ows great promise

It thus seems that methylpentynol, given as elixir of ethylpentynol, provides a safe and reliable premedica on for children There is no increase in emotional pset even if the children are not actually asleep on rival in the anaesthetic room Induction of anaesthesia ith a sleep dose of intravenous thiopentone gives a very mooth and pleasant induction and there is no danger of ostoperative respiratory depression The addition of oscine to the methylpentynol by mouth thereby voiding two injections, is at the moment being investi ated and shows every prospect of being successful

Summary

It is important to avoid emotional trauma in children dmitted to hospital for tonsillectomy especially when hey are under 5 years of age

Simple points in the management of children during heir stay in hospital are outlined

The disadvantages and dangers of using barbiturates r preoperative sedation are discussed

The use of methylpentynol in a flavoured elixir for reoperative sedation is described A follow up of 100 ases showed no difference between the emotional response f those children sedated with pentobarbitone and those eceiving methylpentynol Methylpentynol has a great fety margin and none of the disadvantages of the arbiturates

A sound film has been made illustrating the points the paper

I am indebted to Mr H G Downer and Mr P C Rushton hose cases these were and who performed all the operations I wish to acknowledge the very great help and coöperation I have received from the nurses of the E.N.T wards of Worthing Hospital. The children were visited by Mrs. E E Nevell, some time psychiatric social worker attached to Graylingwell Hospital The expenses of this investigation and of making the film were met by a grant from the research funds of the South West Metropolitan Regional Hospital Board. The photography was under the charge of Mr J Howard Dr R Mac Keith helped with the script of the film

CHEMICALLY IDENTIFIABLE BACTERIAL RESIDUES IN LUNG LESIONS

The syndrome described by Caplan (1953) in coal miners with pneumoconiosis consists in the development of radiologically characteristic pulmonary nodules in patients with concomitant rheumatoid arthritis In a community of South Wales coalminers Miall Caplan Cochrane Kilpatrick and Oldham (1953) found that more than half the men with this characteristic X ray picture also had rheumatoid arthritis compared with only 3% of those with ordinary progressive *massive fibrosis*

Because of our work on the chemistry of the subcutaneous nodules of rheumatic fever (Consden Glynn and Stanier 1953) we were invited by the South Wales investigators to study the chemistry of these various lung lesions with a view to confirming the difference between the Caplan nodule and other forms of pneumoconiotic fibrosis In the course of this work we found that in some samples the hydrolysates appeared to contain α ε diaminopimelic acid (D A P) when examined by paper chromatography Since this amino acid is not a normal constituent of mammalian tissue but is widely distributed among bacteria of various genera and species including *Mycobacterium tuberculosis* it seemed important to establish with more certainty that D A P was present especially as infection was no longer demonstrable by the usual methods of microscopy, culture, and animal inoculation. This method of detection is presented below.

Tissues Studied

(1) *A caseous nodule* obtained by biopsy from a man aged 23 was a typical caseous tuberculoma 1.5–2.0 cm. in diameter with an acellular non-fibrous necrotic centre surrounded by a zone of cellular fibrous tissue 2–3 mm. thick. Occasional foci of epithelioid and giant cells were present in this cellular zone. *No acid fast* bacilli were found despite prolonged search of several sections.

(2) *Tuberculous lung tissue* obtained by biopsy from a woman aged 28 contained several dense fibrous foci acellular *in the centre and only slightly* cellular at the periphery. The apparently necrotic centre, when stained by Gomöri's (1937) method for reticulin, revealed a dense network of fine and coarse collagen fibres with some still finer argyrophil fibrils interspersed with them. No tissue histologically characteristic of tuberculosis was seen, and no acid fast bacilli were found.

(3) *Progressive massive fibrosis*: a sample removed at necropsy from a man aged 55 consisted of jet black and fairly dense fibrous tissue about 1 cm. in diameter and surrounded by a narrow margin of emphysematous lung. The main fibrous lesion consisted of a dense central network of collagen with a surrounding fibrous capsule radiating into the surrounding lung. Similar but smaller nodules were present in the adjacent lung tissue. The acellularity of the fibrous tissue was striking.

(4) *Infective nodules* obtained at necropsy from a man aged 57 consisted of densely pigmented lung with diffuse fibrosis and some nodules up to 2 mm. in diameter formed of interlacing collagen fibres. Cellular reaction was virtually absent from the fibrous areas and the intervening lung tissue.

(5) *A Caplan nodule* obtained at biopsy from a man aged 52 was a sharply defined lesion about 1.5 cm. in diameter. Histologically the main central part of the nodule appeared structureless or faintly fibrillar when stained with hæmatoxylin and eosin, but with silver impregnation this central area was seen to be composed of a dense network of collagen fibres with finer argyrophil fibrils in the interstices. Peripherally there was a band of cellular tissue containing fibroblasts and foci of lymphocytes and histiocytes, but the cells were not in a palisade formation. The microscopic appearance lacked the characteristics of tuberculosis, and the structure of the acellular centre was quite different from that of the subcutaneous nodules of rheumatoid arthritis.

(6) *Normal lung removed* at necropsy from a male town dweller, aged 59, who died of congestive cardiac failure consisted mainly of the dark dusty surface and was used as a control of the other lung specimens.

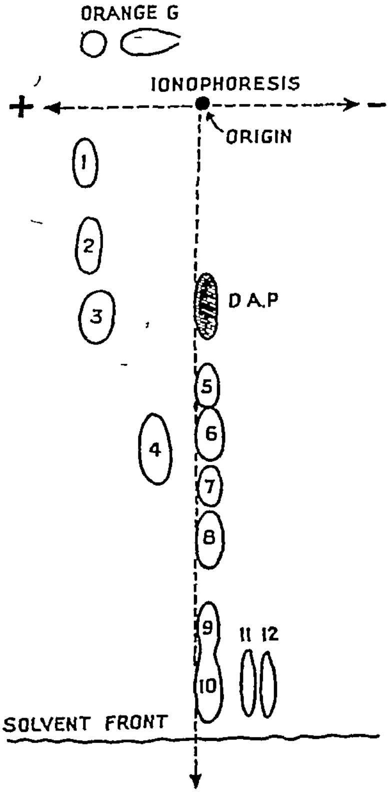
Method of Demonstrating D.A.P. in Lung Lesions

Samples of all the lung tissues were washed with 0.8% saline solution followed by distilled water, dehydrated in acetone, and autoclaved to remove collagen. Tests for D.A.P. as described below were made on the residues, since preliminary chromatography had indicated that in tissues which contained this amino acid, the bulk of it was not extracted by autoclaving. This procedure therefore has the advantage of concentrating the D.A.P.-containing constituents in the test material, because from a half to two-thirds of the organic material of the lung samples was removed by autoclaving. The residues of Caplan nodule, tuberculous lesion, and progressive massive fibrosis after autoclaving contained about one-third of the original organic matter, whereas the infective nodule and caseous nodule residues contained about one-half.

The following simple test for D.A.P. depends on a two-dimensional separation on paper by chromatography followed by ionophoresis at right angles to the direction of chromatography.

The tissue was hydrolysed with 6 N HCl at 105–110°C for 17 hours. Excess acid was removed by evaporation in vacuo. Insoluble humin was separated by centrifugation. A portion of the hydrolysate was treated with excess bromine water and stood for 5 minutes. Excess bromine and acid were removed by evacuation over KOH. The treated hydrolysate was concentrated to a suitable volume, and 5–10 µl. containing the equivalent of 0.25–0.33 mg. of protein was placed on a spot half-way across a sheet of Whatman no. 1 filter paper 24 cm. wide. Chromatography was carried out in water-saturated phenol in an atmosphere of NH_3 (produced from 0.3% NH_3 on the floor of the chamber) for 21–24 hr., by which time the solvent front had travelled about 25 cm. from the origin. The sheet was thoroughly dried and the paper below the solvent front removed. The remainder was suspended and sprayed lightly and evenly with M/20 phosphate buffer, pH 7, the spraying being done first on either side of the chromatogram and finally along the chromatogram itself. The wet sheet was then placed in position in the paper electrophoresis apparatus with the edges of the paper dipping into the electrode compartments containing M/20 phosphate buffer, pH 7. The apparatus consisted of a flat shallow 'Perspex' box designed for holding paper in a horizontal position. Before the current was applied, a drop of Orange G solution was placed above the origin to act as a control. The voltage applied was about 14 V. per cm., and the starting current 0.5 mA per cm. of width. The current was passed for 1 hour, after which the paper was removed, dried, and treated in the usual way with ninhydrin. During the ionophoresis the Orange G separates into two components (red and yellow). The faster (yellow) travels at a similar rate to *aspartic acid and hence is useful for observing progress during* the run. The resulting two dimensional separation (chromatophoretogram) is illustrated diagrammatically in the accompanying figure.

In phenol NH_3 the amino acids which would interfere with D.A.P. are glutamic acid, ethanolamine phosphoric acid, and cystine, all of which occur in animal tissues. The first two, because of their acidic nature, migrate towards the anode in an electric field. Cystine is completely oxidised by Br_2 to cysteic acid (Consden et al. 1946), which besides having a lower R_F value than D.A.P., is also acidic. D.A.P. behaves like the monoamino-monocarboxylic acids and migrates slowly towards the *cathode* because of electro endosmosis and no known amino acid of animal tissue hydrolysate would occupy the same position after two dimensional separation. Tyrosine, if present, is converted by bromine to dibromotyrosine, which migrates slowly towards the anode at pH 7 and has an R_F value in phenol similar to glycine. The basic amino-acids *migrate* towards the cathode.



Chromatophoretogram of a bromine-oxidised protein hydrolysate containing diaminopimelic acid (chromatography in phenol-NH_3, followed by ionophoresis at pH 7)

D.A.P., diaminopimelic acid. 1, cysteic acid. 2, aspartic acid. 3, glutamic acid (ethanolamine/phosphoric acid if present, would occur here). 4, dibromotyrosine. 5, serine. 6, glycine. 7, threonine. 8, alanine. 9, valine. 10, leucine &c. 11, arginine. 12, lysine.

Work at Dewey (1953) describe a method of demonstrating D.A.P., based on a similar principle but this is more laborious and time consuming than the method described above.

A number of solvents can be used for the first chromatographic separation because the interfering components of be subsequently separated by ionophoresis or converted to acidic amino-acids by oxidation However solvents which incorporate acid are a disadvantage because it is impossible subsequently to remove all the acid from the paper This increases the ionic strength of the buffer and hence causes too high a current for convenience in the ionophoretic separation Further if ethanolamine phosphoric acid were present it would only have appreciable ionophoretic mobility at pH 6 or higher (Clarke et al 1955) The acid in the paper would therefore require stronger buffer solutions to raise the pH sufficiently and this would also cause high current This could be overcome by using a lower voltage but the time of ionophoresis would be correspondingly increased The width of the sheet is not important it depends on the dimensions of the paper-electrophoresis apparatus used

Results

The lower limit of detection of D.A.P is about 0·5 µg Hydrolysed fat-extracted *M tuberculosis* by the above test showed a moderately strong D A P spot corresponding to about 5·0 µg Caseous tissue showed a spot of moderate strength (about 2·0–3·0 µg) the Caplan nodule showed a faint but quite distinct spot (about 1·0 µg), and a trace (about 0·5 µg) was found in the non caseous tuberculous lung No D.A.P was detected in the infective nodule, in the sample of progressive massive fibrosis, or in the normal lung

Discussion

D.A.P was first observed in *Corynebacterium diphtheriae* by Work (1949) and in *M tuberculosis* by Asselineau and Lederer (1950) Subsequently many investigations have shown its wide occurrence in bacteria (see Work and Dewey 1953) but it has not been demonstrated in either tissue fluids or tissue hydrolysates of mammals The ability to demonstrate D.A.P even in minute quantities in samples of lung tissue indicates heavy bacterial colonisation at some period in the evolution of the lung lesion Since the method used cannot detect less than about 0·5 µg of D.A.P the concentration of this amino-acid in the positive specimens must have exceeded 1·5–2·0 µg per mg But D A P only constitutes some 2% of the dry weight of those bacteria likely to occur in lung 1·5–2·0 µg therefore represents 5–100 µg of dry bacillus weight This is present in the residue after autoclaving and assuming that only negligible amounts of D.A.P are extracted by autoclaving evidence is thus obtained that lung lesions despite the absence of cultural or histological evidence of infection may contain identifiable bacterial residues resulting from a weight of infection amounting to at least 2·5% of the dry weight of the lesion itself

Moreover with the caseous material the strength of the D A P spot suggested that the bacterial contribution to the lesion was much higher amounting to at least 0% of the lesion These figures must not be taken as evidence that bacterial debris is actually present to this extent since the bulk of the organisms may well have been removed by the normal scavenging and enzymatic activities of the tissues On this hypothesis D A.P should be a component of the highly resistant residue of the bacteria That this is so for *M tuberculosis* has been shown by Colover and Consden (unpublished) in a chemical study of the fraction of the tubercle bacillus that is active in the experimental production of allergic encephalitis (Colover 1954) An active residue remaining after prolonged extraction with fat solvents followed by digestion with proteolytic enzymes still contained D.A.P in readily detectable amounts Some mention should be made of presence of D.A.P in the Caplan nodule and its absence in progressive massive fibrosis. Further investigation of the latter is necessary before this difference is established Prior bacterial infection might be an important factor in pathogenesis of one or both of these conditions.

Two further aspects of these results are worthy of comment

(1) The detection of bacterial debris by the presence of chemically characteristic components might well prove a useful method in the study of lesions of obscure ætiology such as sarcoidosis. The presence of either arabinose rhamnose or mycolic acid would provide further confirmation of the presence of such bacterial residues.

(2) In view of the rôle of tubercle bacilli in the experimental genesis of immunity and allergy, the persistence in the tissues of resistant bacterial fractions might be of great significance.

Summary

A method is described for identifying α ε diamino pimelic acid in some lung lesions

This amino acid was found in a caseous tuberculous nodule, a Caplan nodule, and a sample of non-caseous tuberculous lung tissue It was not found in a sample of "progressive massive fibrosis" nor in an "infective nodule"

The bacterial residues in the caseous nodule represent a weight of infection amounting to about 20% of the dry weight of the lesion

It is a pleasure to acknowledge the coöperation of Dr J Gilson, Dr W E Miall Dr D Rivers, and Dr A L Cochrane, of the Pneumoconiosis Research Unit for supplying tissues and for helpful discussion The infective nodule was provided by Prof. J Gough.

SIMPLIFIED OPERATIVE ROUTINE FOR CARCINOMATOUS OBSTRUCTION OF COLON

B N Brooke
M D Birm. M Chir Camb F.R C.S
READER IN SURGERY UNIVERSITY OF BIRMINGHAM

FOR the treatment of acute colonic obstruction due to neoplasm it has been usual either to do the Paul-Mikulicz operation or to relieve obstruction with a colostomy later resect the lesion and finally close the colostomy Though the Paul Mikulicz method is [illegible] and only requires a second operation for closure of the colostomy it is unsuitable for the purpose of eliminating neoplasm since there is inadequate [illegible] the lymphatic field By the three stage [illegible] temporary colostomy is made as far [illegible] lesion as is practicable, in order to [illegible] adequate resection later; but at the [illegible] the temporary colostomy tends to [illegible] the abdomen and thus the area [illegible]

When obstruction [illegible]

phase of acute obstruction if the two stage procedure is planned It is to draw attention to the value of this method that the following three cases are reported

Case-reports

Case 1 —A woman, aged 70, was admitted on Feb 22, 1954, to the Queen Elizabeth Hospital with acute obstruction of the colon Laparotomy next morning revealed a mobile growth of the rectosigmoid A loop colostomy was constructed in the left iliac fossa as close to the lesion as possible After operation an infected hæmatoma formed in the wound Sixteen days after admission the abdomen was reopened through a low left paramedian incision, thus avoiding the previous site on the right side It was confirmed that the neoplasm of the rectosigmoid was at an early stage , no glands were palpable, and so anterior resection was undertaken The colostomy was detached from the abdominal wall and withdrawn into the abdominal cavity From that moment it was possible to do an anterior resection in the usual manner removing the growth within the pelvis after mobilising the upper rectum and ligating the superior hæmorrhoidal vessels , end to end anastomosis between the mobilised portion of the descending colon and the rectum at the level of the pelvic peritoneal reflexion was a simple matter after removing the sigmoid and rectosigmoid, which contained both growth and colostomy The operation was completed by suture of the laparotomy and colostomy wounds, the latter being drained Recovery was uneventful, and the patient returned home two weeks after the second operation

Case 2 was similar to case 1 as regards site of the neoplasm, but the technique of removal was somewhat different A man, aged 53, was admitted on March 24, 1954, with intestinal obstruction due to a growth found at laparotomy to be adjacent to the brim of the true pelvis The sigmoid loop was long , at the lowest possible site a colostomy was formed in the left iliac fossa After this operation the sigmoid tended to prolapse through the colostomy incision Ten days later the abdomen was reopened through the lower left paramedian incision Because of the bulk of colon exteriorised as the result of prolapse at the colostomy, it was decided to perform the dissection through the paramedian incision but deliver the resected portion through the colostomy wound, so as to avoid contamination which might result from returning the prolapsed portion and the colostomy to the abdomen The splenic flexure was mobilised, and since it was impossible to dissect in the lower part of the left paracolic gutter, the left colonic vessels were ligated at their origin from the medial side, and special care was necessary to avoid injuring the ureter An anterior resection was done with end to end anastomosis between the upper descending colon and the rectum The colostomy and the neoplasm were excised together in the length of colon removed through the colostomy incision The paracolic gutter was drained through the wound in the left iliac fossa which was repaired Convalescence was smooth and the patient returned home twelve days after operation

In **Case 3**, a woman aged 61, the lesion was at the splenic flexure The preliminary laparatomy was done through a lower left paramedian approach , and the colostomy, placed as far to the left in the transverse colon as possible was brought out above the level of the umbilicus through a left trans rectal incision Fourteen days later the left paramedian incision was reopened and was continued upwards to include the colostomy wound and detach the colostomy An excellent exposure was thus obtained, and left hemicolectomy was done with end to end anastomosis of the right transverse colon to the lower sigmoid The paracolic gutter was drained through a stab incision in the flank, and corrugated rubber was placed at the site of the pre-existing colostomy The patient had an undisturbed convalescence and was discharged twelve days later

Management before resection in all cases has included colostomy washouts , and by mouth for three days streptomycin 1 g twice daily, alternatively oxytetracycline 250 mg six hourly, or phthalylsulphathiazole 2 g thrice daily, with the same drug instilled as a suspension into the distal loop of the colostomy At operation it has been found best to tie a dry swab over the colostomy and to make no attempt to close its opening with sutures, since this tends to be ineffective and promote bleeding and thus the possible spread of contaminants In the first case oxytetracycline, and in the second case strepto-mycin, was instilled around the area of dissection and anastomosis before closing the peritoneum This was done because of the wound infection complicating the one, and the prolapse increasing the possibility of contamination in the other , no local application of this sort was made in the third patient Case 1 was given oxytetracycline after operation because pus from the previous incision was encountered on reopening the abdomen No drugs of this sort were given to cases 2 and 3 after operation, and routine chemotherapy is avoided at this stage since these drugs are better kept in reserve for possible complications

The neoplasm itself has always been covered at an early stage with a surgeon's mask, the strings of which are tied tightly around the bowel above and below the lesion to prevent exfoliated malignant cells from spreading to the site of anastomosis, where they may be implanted (Cole 1952) while the mask itself prevents direct exfoliation and implantation due to manipulation

Conclusions

A method is described for treating carcinomatous obstruction of the colon and rectosigmoid At the initial operation to relieve obstruction, the colostomy is placed as close to the growth as possible so that both may be resected together at a second and final operation

The advantages include a reduction from three to two in the number of operative stages and therefore reduced risk of morbidity , shorter stay in hospital , and greater freedom of manœuvre, permitting wider excision of the area of lymphatic spread

PAROXYSMAL NOCTURNAL HÆMOGLOBINURIA

MARCHIAFAVA—MICHELI SYNDROME

DAVID DOUGLAS
M.D Glasg , F R F P S
CONSULTANT PHYSICIAN AND PHYSICIAN TO OUTPATIENTS, ROYAL INFIRMARY, GLASGOW

JAS C EATON
B Sc , M.B Glasg , F R.I C
CONSULTANT BIOCHEMIST AND LECTURER IN PATHOLOGICAL BIOCHEMISTRY IN THE UNIVERSITY OF GLASGOW

CHRONIC hæmolytic anæmia with paroxysmal nocturnal hæmoglobinuria (P N H) is fairly rare Crosby (195 remarks that 162 cases have been reported since Marchiafava's first description in 1928, but probably the true incidence is much greater The ætiology is unknown The present concept is of a cell defect shared by erythrocytes, leucocytes, and platelets This defect of unknown nature but possibly one of cell stroma protein, renders the erythrocyte abnormally susceptible to a hæmolytic system present in normal plasma

It has been claimed that electron microscopy in some cases has shown abnormal structure in the envelope of the hæmolysed red cell (Matthes et al 1951) Electron microscopy in the case presented below did not support this contention

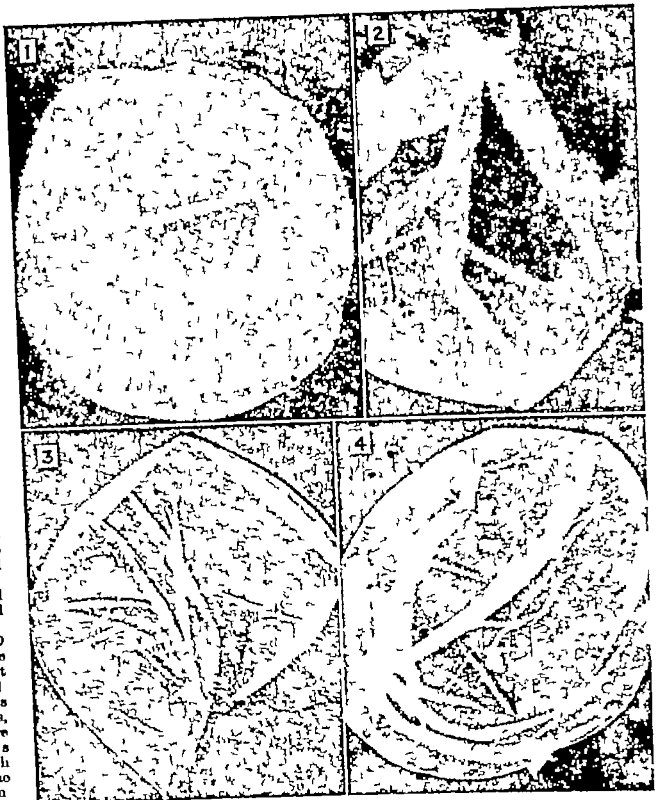
Case-report

A married woman, aged 35, with one child aged 11 years and no history of any previous illness of consequence, she noticed hæmoglobinuria in 1943 while she was pregnant She had it on only one occasion, but she was found, during the puerperium, to have a mild anæmia which did not respond to iron therapy She remained in her usual health thereafter until August, 1953, when she was admitted to hospital as a contact carrier of *Salmonella typhimurium* She was given a course of oxytetracycline, after which her stools were negative r pathogens. She was again found o have an anæmia not responding o iron. Shortly afterwards hæmoglobinuria recurred being present n the first morning specimen of urine but not at other times of the day Her doctor detected slight jaundice which remained, with some fluctuation until readmission to hospital in December 1953 The patient felt tired and weak and had spells of dizziness in the morning lasting about an hour She knew by a feeling of general malaise when she would pass bloodstained urine. There was no history of anæmia or jaundice in her family or of exposure to hæmolytic drugs

The patient was a small and slimly built young woman who was pale and had a lemon yellow tint and a few soft and slightly enlarged glands on either side of the neck but not elsewhere No enlargement of liver or spleen was detected No abnormality was found in the cardiovascular respiratory nervous or alimentary systems. The morning urine was the colour of port wine and contained albumin but no bile

Laboratory Investigations —Examination of the blood showed Hb 9·8 g per 100 ml red cells 3,030 000 per c.mm., and white cells 5400 per c.mm A red-cell fragility test showed that hæmolysis began in 0·5% solution and was complete in 0 35% (control 0 45% and 0·4% respectively) The blood group was A Rh D positive The probable genotype was R2 r (c̄DE c̄de) The direct Coombs test was negative; and when the patient s serum was tested against a large panel of cells, no irregular antibodies were detected Ham s test and Crosby s modification of Ham s test both showed strong hæmolysis of the patient s cells by homologous serum whereas there was no hæmolysis in the control tests. In addition the patient s cells were incubated with an anti A serum which contained a weak anti A hæmolysin; the control cells showed slight hæmolysis, whereas the patient s cells were considerably hæmolysed The Wassermann and Donath Landsteiner tests were negative Between periods of hæmoglobinuria the serum contained small amounts of oxyhæmoglobin and considerable amounts of methæmalbumin Shortly after the passing of dark urine it contained a large amount of oxyhæmoglobin and a small amount of methæmalbumin. The methæmalbumin was never demonstrable spectroscopically and was only detected by plotting absorption curves on a spectrophotometer Electrophoresis of the serum did not reveal any abnormality; likewise electrophoresis of the hæmoglobin within the cells revealed no difference in mobility from that of control samples The dark samples of urine contained variable amounts of methæmoglobin and oxyhæmoglobin. When the urine was freshly passed the amount of methæmoglobin was usually considerable but on standing it disappeared rapidly increasing alkalinity converting it to oxyhæmoglobin. The deposit revealed a few hyaline casts numerous squamous epithelial cells (a small proportion of which contained iron granules within the cells) and very numerous amorphous particles of iron-containing material. No red blood-cells were seen. The urinary excretion of urobilinogen was 3 mg daily The fæces were of normal colour The fæcal excretion of urobilinogen was 238 mg daily

Progress —Hæmoglobinuria ceased spontaneously after five weeks. It has not so far recurred but there has been no improvement in the anæmia. The patient s general condition remains moderately satisfactory There have been no thrombotic or infective complications For these reasons it has not been deemed advisable to give a transfusion of washed cells or anticoagulant drugs which may have a temporary ameliorating effect on hæmolysis



Appearance of normal and P N H erythrocyte ghosts on electron microscopy: 1 normal erythrocyte unshadowed (× 8000); 2, P N H erythrocyte unshadowed (× 12,000); 3 normal erythrocyte shadowed with Au and Pd (× 8000); 4 P.N H. erythrocyte shadowed with Au and Pd (× 8000)

Electron Microscopy —The patient s red cells were examined by electron microscopy and some of the results are shown in comparison with those of normal cells in the accompanying figure The cells, obtained from samples prepared as shown below were separated from plasma or from serum by spinning and hæmolysed with 5 10 or 30 volumes of water The envelopes were separated by centrifuging and were treated with 1% osmium tetroxide for 30 minutes The material was again spun, washed resuspended to a suitable concentration and sprayed on to a supporting film for microscopy Some films were shadowed with gold and palladium at 15 C The following preparations were examined thus: (1) citrated blood; (2) cells from blood allowed to clot spontaneously; (3) cells from blood defibrinated by shaking with glass beads (4) cells from blood defibrinated by stirring with a glass rod; (5) as (3) but after allowing the blood to stand for some days before defibrinating; and (6) as (4) but allowing the blood to stand for some days. Samples 4 5, and 6 were unshadowed None of the photographs showed any significant differences between normal and P.N.H cells. There was no evidence of the spotty or "mesh like" appearance described by Matthes et al (1951)

Discussion

The lytic mechanism in P N H has been studied by many workers, notably Crosby (1953) and Crosby and Bell (1951), the current views and the literature being well reviewed by Crosby (1953) It has been shown that both lytic and inhibitory factors are present in normal plasma, but that the abnormality in P N H does not lie in these factors If P N H cells are placed in normal plasma they tend to undergo lysis, this process being hastened by acidification, normal erythrocytes are not lysed by P N H plasma This explains why transfusion of a P N H patient with normal blood tends to produce a lytic crisis The system present in the normal transfused plasma attacks the abnormal cells of the patient If washed cells only are given, the normal plasma system being absent, no lysis results

Despite much examination no satisfactory explanation is forthcoming for the widely observed tendency of P N H patients to get lysis during sleep It has been repeatedly suggested that diminished excretion of respiratory carbon dioxide during sleep reduces the plasma pH (T H Ham 1939, G C Ham and Horack 1941, Matthes et al 1951), but the evidence for this is not entirely conclusive (Peterson 1949, Crosby and Bell 1951) From in-vitro experiments Peterson (1949) suggested that carbon dioxide has some specific effect not shared by other acids, but Crosby and Bell (1951) and Ham (1939) could not confirm this It appears clear that the lytic tendency is associated with sleep as such and not with posture or time of day Increase of pulmonary ventilation in a respirator during sleep will prevent lysis (Ham 1939, Ham and Horack 1941)

Paroxysmal nocturnal hæmoglobinuria does not appear to be hereditary, only one of a pair of uniovular twins had the abnormality (Crosby 1953) The onset is usually in adult life, the sexes are equally affected It has been suggested that the disease is due to some unknown sensitisation Experiment has failed to reveal any abnormality in the hæmoglobin (McIlvaine and Beard 1951 and our own results) The apparently normal condition of plasma and hæmoglobin in this disease points to the red-cell envelope as the seat of the abnormality Despite the claim by Matthes et al (1951) to have demonstrated lacunæ and a mesh like appearance in electron microphotographs of P N H cells, our findings showed no significant difference between P N H and normal cells Sundharagiati and Wright (1953) found changes similar to those described by Matthes et al in a variety of blood dyscrasias and believe that these were due to artefacts

Splenectomy has been found to be useless or even harmful Treatment with alkali is ineffective (Buell and Mettier 1940), and numerous hormones and drugs have been tried without success by other workers Crosby (1953) showed that dicoumarin may help Thrombin destroys the normal heat stable inhibitor of lysis By preventing conversion of prothrombin to thrombin dicoumarin inhibits this destruction In emergency, transfusion with homologous cells washed free from plasma is effective

Summary

A case of paroxysmal nocturnal hæmoglobinuria is described

The laboratory findings were characteristic Some hæmolysis was present even when there was clinical remission Electrophoretic examination of the hæmoglobin revealed no abnormality Electron microscopy of the lysed red blood-cells showed no difference between their envelopes and those of normal erythrocytes

We wish to thank Miss H. M Laird, of the Beatson Memorial Hospital, for preparing and reporting on the electron microphotographs, Dr J Wallace, of the West of Scotland Blood Transfusion Service, for serological examination of the blood, and Dr David Smith, of Glasgow Royal Infirmary, for permission to examine the patient

ON THE SEX OF CANCER AND TERATOMATA CELLS

AMÂNDIO S TAVARES
M B Oporto
ASSISTANT, DEPARTMENTS OF GENERAL AND ANATOMICAL PATHOLOGY, FACULTY OF MEDICINE, OPORTO UNIVERSITY, PORTUGAL

A MORPHOLOGICAL sexual difference in the nuclei of nerve-cells of cats was found by Barr and Bertram (1949, 1951), and later work showed that a chromatin mass called "sexual chromatin" or "corpuscle of Barr" is seen in about 75% of nuclei of various tissues in females, but is seldom detected in males (Barr et al 1950, Graham and Barr 1952)

These findings have been applied to the diagnosis of sex in other animals and in man (Moore and Barr 1954). For instance, nuclear sex has been studied by this method in transvestites (Barr and Hobbs 1954), hermaphrodites (Moore et al 1953, Barr 1954), and Turner's syndrome (Polani et al 1954) Using a slightly modified technique, Emery and McMillan (1954) say that, except for some doubtful results obtained in necropsy material in the newborn, the method is reliable when applied to children

Hunter and Lennox (1954), who examined spino-cellular epitheliomata of the skin, conclude that cancer cells are of the same sex as the patient, but, as regards teratomata, 5 out of 9 in males were heterosexual whereas 12 teratomata in women were all of the same sex as the patient If this latter finding is applicable generally, we will have to revise our ideas of the genesis of teratomata

Meanwhile we add to the findings of Hunter and Lennox (1954) and of Cruickshank (1955) our findings in 34 teratomata and 110 cancers

Method

We used formalin fixed paraffin embedded sections 5–8 μ thick stained with hæmatoxylin and eosin, and

TABLE I—SEX OF CANCER CELLS

Tumour	Sex of patient					
	Male			Female		
	Average (%) no of cases		Range (%)	Average (%) no of cases		Range (%)
Carcinoma of skin	5 9	24	1 5–17 0	72 9	27	[illegible]
Undifferentiated carcinoma of skin		2	1 0– 4 0		3	[illegible]
Primary carcinoma of liver		1	11 5		3	[illegible]
Adenocarcinoma of stomach	5 6	5	2 5– 9 5	69 8	5	[illegible]
Papillary carcinoma of bladder	6 4	5	3 0–12 0	70 2	5	[illegible]
Adenocarcinoma of ovary				73 3	5	[illegible]
Seminoma of testis	4 0	5	3 0– 5 5			
Carcinoma of kidney	7 5	5	4 0–11 0	71 9	5	[illegible]
Myosarcoma	8 6	8	5 5–15 0		2	[illegible]

TABLE II—SEX OF TERATOMA CELLS

Sex of patient	Sex of teratoma cells: Male: Hunter and Lennox (1954)	Male: Cruickshank (1955)	Male: Present investigation	Male: Total	Female: Hunter and Lennox (1954)	Female: Cruickshank (1955)	Female: Present investigation	Female: Total
F					12	2	25	39
M	4	2	5	11	5	1	4	10
Total	4	2	5	11	17	3	29	19

χ^2 (for 1 : 2 ratio) = 1·999 P = 0·106
χ^2 (for 1 : 1 ratio) = 0·0476 P = 0·962

controls were stained by the Feulgen method. We found fixation to be of greater importance than the method of staining.

Counts were made of nuclei containing the sexual chromatin, as defined by Barr and his colleagues, and percentages were established for at least 200 cells. Doubtful nuclei were counted as half positive, half negative. Immature and degenerated cells were excluded and only one nucleus was examined in the multinucleated elements so commonly found in cancer.

This method gave statistically significant results ($P = 1 \times 10^{-11}$) with a relatively small standard deviation (s = 2·5), in the case of normal skin cells of 40 adults, the sexes being well separated (females 60–80%, males 1–18%) and the two frequency curves showing diverging skewness.

Results

Cancer

In 110 sundry malignant tumours, taken at random for each variety from the cases registered in the department of anatomical pathology in the University of Oporto, the sex of the patient and that of the tumour were the same (table I). The range of results shows no significant difference between normal and cancer cells, and identical percentages were obtained when both were examined in the same section. Neither localisation nor type of neoplasm influenced its 'sex'; the only exceptions were two undifferentiated carcinomata of the skin in women; the low figures (27% and 55·5%) may be explained by the immaturity of the nuclei in these neoplasms.

The number of chromatin-containing cancer cells and mature histiocytes in the stroma of the tumour were counted in 20 cases and differed very little (t = 0·632, d.f. = 10). The histiocytes proved much more reliable than epithelium, because in the undifferentiated carcinomata mentioned above the histiocyte-counts were 70·0% and 74·5%.

Teratomata

Our findings in 34 teratomata (25 from women and 9 from men) were very similar to those of Hunter and Lennox (1954): all 25 from women were 'feminine', whereas 4 of the 9 from men were 'masculine'. If we combine our findings with those of Hunter and Lennox (1954) and Cruickshank (1955) we find that 48% of teratomata in males are hetero-sexual. This fact argues against two current theories of the genesis of teratomata: the blastomere theory and that of parthenogenetic division of a diploid cell. On the other hand, not much support is lent to the theory of gamete (or at least haploid cell) conjugation proposed by Hunter and Lennox (1954), which calls for a ratio of 1 XX : 2 XY : 1 YY teratomata. According to Moore and Barr (1954) only the pair of XX chromosomes determine the appearance of sexual chromatin. This reduces the genetic ratio to 1 XX : 3 (XY + YY) or, if YY cells do not survive (and we know very little on this subject), to 1 XX : 2 XY. The χ^2 test of departure gives a probability rather close to the statistical level of significance (table II).

The objection that teratomatous material, since it is often either undifferentiated or immature, is unsuitable for this study does not hold, at least for our series: only nuclei from mature epithelial, connective, and nervous tissue were counted. On the other hand, if lack of cell differentiation (which may only cause a depression in percentages, as we have shown) influenced our results, these would be reversed and heterosexuality would be found in women alone.

A far greater number of teratomata will have to be studied before any theory emerges from these findings. However, one explanation of a 1 : 1 ratio is, perhaps, the parthenogenetic division of haploid cells followed by chromosome reduplication, forming 100% of XX cells in the female, and 50% of XX and 50% of YY cells in the male. Of course this means attributing a pair of YY chromosomes to the cells of some teratomata, and we do not know anything about their viability.

LOCAL TRANSMETATARSAL AMPUTATION IN ARTERIAL INSUFFICIENCY OF THE LOWER LIMB

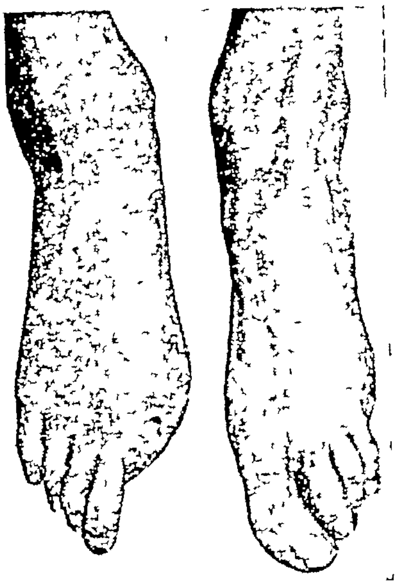
A. G. NORMAN
M.A., M.B. Camb., F.R.C.S.
SENIOR SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL, LONDON

ARTERIAL insufficiency of the lower limb is nowadays treated more conservatively than formerly, preserving as much of the limb as is compatible with healing and sound function. In gangrene of the foot amputation at the metatarso-phalangeal joint commonly proves unsatisfactory, and in the past these unsuccessful cases were treated by high amputation. We now attempt to save more limbs by local transmetatarsal (ray) amputation.

In the present series of 12 cases involving 14 limbs with gangrene of toes, only one of the five toes was involved in 10 limbs. This suggests that there must be some local fault in the circulation of the affected toe. Our arteriographic studies have led us to believe that gangrene in the arteriosclerotic patient results from multiple blocks, and we suspect that in these cases the final block is in the plantar *metatarsal* arteries as they pass the head of the metatarsal bones (Rob 1954). Although the toes, unlike the fingers, have *both* dorsal and plantar digital arteries, it is the plantar arteries that carry most of the blood supply.

In local transmetatarsal amputation the toe and the head of the corresponding metatarsal bone are removed through an anterior racket incision. The aim is to amputate above the level of the arterial block. Great care must be taken to clear away all splinters of bone, since these, if unremoved, delay healing.

Of the 12 patients (9 men, 3 women), whose average age was 61·5, all had diffuse arterial disease and 5 were diabetic. The main manifestations in the 14 affected limbs were: *dry gangrene* (6 cases), *ulceration* (5), and



Foot after local transmetatarsal amputation of right first toe and left fifth toe

cold blue toe (3), and the average length of history was four months In 5 cases these manifestations had been preceded by claudication in the calf

The digits most commonly affected were the first, fourth, and fifth The numbers affected in the 14 limbs were first digit, 4, second digit, 1, third digit, 1, fourth digit, 7, and fifth digit, 5

The results at three to fifteen months after operation were as follows healed, 7 (primary healing 5, delayed healing 2), unhealed, 2, required high amputation, 5 Thus the failure rate was 36%, which is similar to the 37% in a series of total transmetatarsal amputations described by Warren et al (1952)

Analysis does not reveal any sign by which failure can be predicted Failure was unrelated to age, sex, or the presence of diabetes

This operation is designed to remove as little as possible of the gangrenous limb McKittrick (1946), McKittrick and Risley (1949), Furste and Herrmann (1948), and others have attempted to achieve this end by total transmetatarsal amputation, thereafter the foot functions well (unlike the state after amputations at the tarsus by the method of Lisfranc and Chopart), and their results are similar to those described here

After local transmetatarsal amputation the healed foot (see figure) is functionally satisfactory, and the limited follow up in the series described here shows that the wound remains satisfactorily healed In 1 of the diabetic patients a perforating ulcer of the foot developed, but the amputation site remained healed

I am indebted to Prof George Perkins for introducing me to this operation, to Mr F B Cockett for criticism and advice, to the physicians and surgeons of St Thomas's Hospital for permission to describe their cases, and to Mr K G Moreman for the photograph.

Medical Societies

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE 54th meeting of this association was held in Douglas, Isle of Man, on April 13–15 We publish summaries of some of the papers presented at the meeting

Typing in Epidemiological Investigations

Dr W H BRADLEY said that Griffith had first introduced serological typing of hæmolytic streptococci in 1926, and by 1934 a range of 27 reference types was available Craigie and Felix had shown in 1938 that bacteriophage typing of *Sal monella typhi* was practicable, and by 1947 they had prepared a couple of dozen reference phages The significant fall in the mortality of streptococcal disease (particularly puerperal sepsis) between 1934 and the advent of sulphonamides probably reflected the increase in the possibility of outbreak control stimulated by the Griffith's typing

The mortality of enteric fever in the United Kingdom had fallen away more rapidly than in other European countries, and this improvement coincided with the introduction of phage-typing Dr Bradley thought that because typing made epidemiological investigations more convincing and more fun their quality was improved and preventive medicine became more effective Moreover, epidemiological and ætiological concepts had been reshaped The rôle of type 12 and to a lesser extent type 4 streptococci in nephritis was an example It was now realised that the many distinct serological or phage types within a species were acting independently and that their specificity was enduring

Antigenicity of Toxoids and Sympathomimetic Drugs

Dr J UNGAR described how water insoluble mineral carriers such as aluminium or calcium salts, tapioca, oils and fats, and, recently, bacterial suspensions, had been used to increase the efficiency of prophylactic toxoids and thereby reduce the number of injections required Their presence caused local irritation, which was most severe with aluminium and calcium salts and least severe with bacterial suspensions, he had used *Hæmophilus pertussis* vaccines successfully in the past

As the use of vaccines might be undesirable in hypersensitive persons, Dr Ungar had tried to improve the antigenic efficiency of diphtheria toxoid by altering the rate of absorption with drugs exerting a local tissue effect Adrenaline hydrochloride (1 in 1000 to 1 in 2000), benzedrine hydrochloride (1 in 250), ephedrine hydrochloride (1 in 250), and histamine (0 5 μg per ml) had been used Two amines, β phenylethylamine and phenylethylamine acetate, which have no vasoconstrictor action, were included as controls When tested in guineapigs the sympathomimetic vasoconstrictors greatly enhanced the response to diphtheria toxoid Combination with histamine caused only slight enhancement and the two control amines did not affect the response to the toxoid Vasoconstrictors might prove useful for enhancing the efficiency of diphtheria toxoid, especially when children hypersensitive to injections of antigen were being immunised

Lung Carcinoma in Hæmatite Miners

Dr J STEVEN FAULDS said that the incidence of primary cancer of the lung in iron ore miners in Cumberland over the last twenty three years was 9 4%—four times that found in a control group of males of similar age and habits, but different occupation. The site of the tumours corresponded to the areas where the characteristic massive fibrosis developed, and the primary lesion was not in the main bronchus, but in a peripheral lung field The observed association of squamous celled lining to a chronic abscess cavity and a squamous carcinoma in the same area suggested that the tumour arose in the sidero silicotic mass Since silicosis was a frequent finding in other kinds of mining and an association between silicosis and bronchial cancer was not common, it was difficult to give a reason for the increased frequency of carcinoma found in iron ore miners

Lower-nephron Nephrosis

Dr S SEVITT showed that distal tubular necrosis (lower nephron nephrosis) in the kidneys of burned patients was commoner among those who had an adequate or normal flow of urine than in those with severe oliguria or anuria Clinically and biochemically there were uræmic and non uræmic forms with little or no oliguria The uræmic group was important to diagnose because the recent advances in therapy may reduce its high fatality Morphologically these kidneys showed a *diffuse* distal tubular necrosis in which hæmoglobin casts were prominent Many nephrons were involved and although the morphology was no different from that found in those with anuria or severe oliguria, tubular function was impaired

The finding of non-oliguric uræmia in an injured man with histological distal tubular necrosis of the kidneys indicated that the phenomenon was not restricted to burned subjects In the non uræmic condition there was no significant azotæmia during the illness, and death was due to non renal complications. Histologically the kidneys of these patients should show either a *focal* type of distal tubular necrosis, associated with few casts and affecting only a minority of the nephrons, or the healing or healed evidence of a recent focal attack.

Blood-ammonia Levels in Liver Disease

Mr A G Riddell described experiments on dogs with portacaval anastomoses which had shown that a neurological disorder can be produced in these animals by intoxication with ammonia Histological examination of the brains of these dogs showed the same change in the protoplasmic astrocytes as in patients dying in hepatic coma In hepatic coma a raised blood ammonia level was found The type of hepatic coma that followed bleeding from œsophageal varices was analogous to the syndrome seen in dogs and the ammonia was derived from the blood in the alimentary tract While blood ammonia determinations were required in the diagnosis and management of unusual cases, they were not required in the routine treatment of hepatic coma.

Fibrinous Vasculosis

Dr A. C Lendrum suggested this term for the deposition in blood vessel walls of a material giving the staining reactions of fibrin. The commonest cause of this was severe stagnant ischæmia, as in infarction or torsion Other causes were drug-induced hyperergic arteritis extreme hypertension, polyarteritis nodosa and occasionally acute rheumatic disease disseminated lupus erythematosus and dermatomyositis The fibrin was commonly seen under an intact endothelium sometimes as a complete ring round the intima From this level it either seeped into the wall (vessels of infarcted zone) or was injected across the media (in extreme hypertension) to spread out along the external elastica through which it may erupt focally At sites where a layer was traversed, there was in all types of fibrinous vasculosis a stretching and distortion of the nuclei as if they had been subjected to mechanical extension. Gross cellular aggregation was seen in and around a few some or all of the affected vessels. Intravascular thrombosis was uncommon except in small vessels, even when the vessel wall was a mass of fibrin

The most extreme degree of fibrinous vasculosis had been seen in the pulmonary vessels in 2 cases of mitral stenosis; and the next degree in infarcted organs. The three forms of fibrinous vasculosis, the stagnant hypertensive and hyperergic, appeared to be histologically indistinguishable All might be regarded as a form of exudation due to an upset between the pressure in the vessel and the permeability of the lining

Hæmophilia and Christmas Disease

Dr Rosemary Biggs discussing the diagnosis of these ditions said that the laboratory tests of clotting function t have been used were the whole blood clotting time the thrombin-consumption test and the thromboplastin eration test. In hæmophilia the clotting time was pro ged in more than half of the patients, but patients who quite severely affected may have a normal clotting time ilarly the prothrombin-consumption test usually gave ormal results in hæmophilia, but with some samples ults were normal The thromboplastin generation test e more reliable results in hæmophilia blood than either the other tests, and using this technique it was possible to tinguish patients with hæmophilia from those with Christ s disease About 10% of patients previously diagnosed having hæmophilia were found to have Christmas disease the patients with Christmas disease many were rather htly affected with a normal clotting time and consumption prothrombin

Interstitial Emphysema in the Newborn

Dr John L Emery in a consecutive series of 100 infants ing within seven days of birth had found that 7 out of f- ll term children had died with interstitial emphysema ter congenital deformities it was the commonest single cause of death The condition was spontaneous and not due to artificial respiration it was probably caused by the expulsive efforts of crying in lusty infants who had inhaled vernix or mucus.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

Diamox in the Treatment of Glaucoma

The 75th congress of the Ophthalmological Society of the United Kingdom, held in London on April 28–30 included a symposium on 'Diamox' in the Treatment of Glaucoma Diamox (2-acetylamino 1 3 4 thiadiazole 5 sulphonamide) has been known for some years to have a powerful inhibitory effect on the enzyme carbonic anhydrase and it has been used in the treatment of congestive heart-failure because of its diuretic effect[1]

Mr E S Perkins analysed the results in 58 cases treated at Moorfields Eye Hospital, and confirmed the value of this drug in controlling all of the major categories of glaucoma in about 50% of all cases—congestive glaucoma, simple glaucoma and glaucoma secondary to iritis and to trauma—the tension was brought well under control while of the remaining cases about half were controlled partially or for a short period This effect was potentiated by the simultaneous use of miotics The dosage suggested was 500 mg initially followed by 250 mg six hourly after a few days this dose could generally be reduced to twice or thrice daily at which level it should be maintained Side-effects were rarely disturbing diuresis and paræsthesiæ were usually very transient Mr Perkins concluded that the particular value of diamox was in the control of acute congestive glaucomatous crises where it allowed the eye to quieten for a subsequent drainage operation; in certain cases of simple glaucoma where miotics had failed to achieve effective control, and in cases of iritis glaucoma in which the tension could be controlled until the initiating iritis had been allayed

Dr John Gloster described his estimation of the effect of diamox on the intra-ocular pressure of normal rabbit eyes. He found that an intravenous injection of diamox caused a drop in the intra-ocular pressure within one minute the speed of this action suggested that it was due to a direct effect on the secretion of aqueous humour in the ciliary body The changes estimated by the insertion of a cannula into the aqueous, were significant only with doses larger than those used clinically

Dr Maurice Langham reported the results of further experiments on rabbit eyes Observations were made first on the effect of diamox on the distribution of bicarbonate between the aqueous humour and the plasma, since it might be assumed that the inhibition of the production of hydroxyl ions would decrease the osmotic pressure of the aqueous and thereby reduce its formation The influence of the drug was assessed according to the permeability of the blood aqueous barrier and the flow of the aqueous humour by measuring the rate of accumulation of fluorescein in the aqueous humour after intravenous administration It was found that, although the bicarbonate in the aqueous diminished after the administration of diamox its concentration relative to that in the plasma was unchanged The method by which diamox reduced the formation of the aqueous thus remained uncertain; the results of his experiments did not show whether diamox in fact exerted its effect by its systemic action or through a non specific inhibition of aqueous secretion

Prof G P Sourdille (Nantes) reported clinical observations which agreed essentially with those described by Mr Perkins

Reviews of Books

Practical Obstetric Problems

IAN DONALD, M B E, M D Lond, M R.C O G, regius professor of midwifery, University of Glasgow London Lloyd-Luke 1955 Pp 578 45s

IN many ways this is an admirable book, but it is not addressed consistently to any particular group of readers, and one cannot easily say just what kind of book it is. The title and part of Professor Donald's preface suggest that it is largely a reference work for the practising obstetrician, but, though the practising obstetrician will find much profit and enjoyment in its discussion of controversial problems, it leaves out things one would expect it to contain It is not a textbook, for the anatomical and physiological ground-work of obstetrics has been deliberately omitted Perhaps it will be of most value to those who have a little experience of obstetrics and are sitting a higher examination —though these will have no need of the details of simple obstetrical procedures (such as toilet of the vulva before forceps delivery) nor of some of the discussions of matters that belong to undergraduate rather than postgraduate teaching

The points at which fellow experts will take issue with the author mostly concern manipulative obstetrics In the section on manual correction of the fœtal head in the occipito posterior position, a good method is described for altering the fœtal position, but no reference is made to the alternative techniques, such as rotating the shoulders by the internal hand or correcting the malposition by placing the hand over the fœtal face In the section on breech delivery the description of the rotation of the anterior shoulder posteriorly does not mention the desirability of over correction if the back of the fœtal head is to remain directed to the symphysis The statement that "the lateral position for forceps delivery has been abandoned" takes no account of those who are convinced that the lateral position confers at least the two advantages of a reduced risk of anæsthesia and less perineal damage Some, too, will disagree with the opinion (on twins) that "if a general anæsthetic has been necessary in the course of delivery of the first child it is usually preferable to discontinue it while awaiting the arrival of the second." Sweeping statements such as "Cæsarean myomectomy is an indefensible operation" and "undoubtedly" routine X ray pelvimetry in all primigravidæ "will come in time" belong perhaps to the cut and thrust of debate rather than to the printed page

Against these objections must be set the important fact that the book conveys much of the author's zest Some of its parts, and some of its sentences, are too long, but it is often very readable Many will be grateful for its robust, uncompromising approach, and above all for its stimulating enthusiasm

Memoirs of My Nervous Illness

DANIEL PAUL SCHREBER Translators and editors IDA MACALPINE, M.D, RICHARD A HUNTER, M.D, M.R C.P, D.P M London Wm Dawson 1955 Pp 416 £1 15s

AUTOBIOGRAPHICAL accounts of mental illness are valuable documents, especially when written by patients of high intelligence, gifted with powers of self-observation and accurate recollection These qualities were undoubtedly possessed by Daniel Schreber, a judge of the supreme court in Saxony, who developed a severe schizophrenic illness in late middle life His account of his experiences in this illness, first published in 1903, was the subject of a study by Freud eight years later Freud's paper has become important in the development of psycho-analytic theory about psychoses, and the Schreber memoirs are often mentioned, but usually by people who have not read them, because the book has become scarce and has never been translated from German Dr Macalpine and Dr Hunter have now made good this deficiency

Their translation does not always run smoothly, but it may well be a faithful reproduction of Dr Schreber's style Schizophrenics do not write with terse and graceful precision, nor perhaps do judges, and the reader is willing to accept the translators' disconsolate reference to Schreber's cumbersome and involved language They give examples of his neologisms in an appendix They have fallen into a few well known traps—such as translating *Moment* as "moment" instead of "factor"—but these are trifling blemishes in a large undertaking Besides the *memoirs*, the book contains a clinical and historical introduction by Dr Macalpine and Dr Hunter, a reprint of their informative psychopathological article on the Schreber material, and translations of the psychiatric reports on Schreber, the legal statement in which he asked to be given back control over his affairs, and the judgment of the court which heard this appeal.

The translators ride a few hobby-horses, as their incidental polemic against physical forms of treatment shows, but the grateful reader will not begrudge them this by-product of their labours for his benefit, he may even, unless an orthodox psycho-analyst, find their irreverent re-examination of some central issues of Freudian psychopathology stimulating

Examen clinique et traitement d'un endocrinien

A. LICHTWITZ and R PARLIER, Hôpital Lariboisière Paris Paris L'Expansion scientifique française 1954 Vol I Pp 456 Fr 5200 Vol II Pp 392 Fr 4800

To apply recent advances in endocrinology demands some understanding of the experimental techniques which produced them Doctors are often ill equipped by their training to follow the methods of diagnosis and treatment that have evolved Dr Lichtwitz and Dr Parlier, in this frankly didactic account of endocrinology in its modern setting, have, by their attention to layout, tables, and diagrams, done much to explain the scientist's findings to the clinician In the preface they write "We hope the jealous guardians of pure biological science will pardon certain abuses of simplification, remembering that our aim is to reach not only those doctors who wish to perfect their knowledge of modern endocrinology, but all those who are harassed by the problems of general pathology" But the questioning and thoughtful reader may be disappointed

Dr Lichtwitz and Dr Parlier deal first with some general principles and then with the hypophysis, the thyroid, the ovary, and, in the second volume, with the testes and the suprarenal Throughout, the influence of Selye makes itself strongly felt The book is a useful guide to the French literature and in particular to the authors many original articles. It is lavishly produced, and misprints are mostly in the references but the index is unfortunately sketchy

The Challenge of Man's Future

HARRISON BROWN London Secker & Warburg 1954 Pp 290 21s

Prof Harrison Brown is a chemist with an expert's knowledge of the earth's material resources, an American's optimism about human capacity, and a citizen of the world's awareness of the rake's progress and the fateful hour Like Sir Charles Darwin he sees the ultimate consequence of an uncontrolled growth of population and a spendthrift use of our resources, but he is not convinced that there is no escape from this doom

He foresees three possible patterns of life reversion to the agrarian existence of the pre-industrial period a completely controlled, collectivised industrial society in which war has been abolished, new energy sources are utilised, and population is kept stable, a world wide free industrial society, labile but capable of permanence The last, the most desirable and to our favoured Western minds the expected outcome of "progress," is the most difficult to achieve since it requires efforts beyond anything human beings have so far compassed They must adapt themselves to constant change, preserve freedom while accepting control of reproduction, aggression, and other old desires, and use their intelligence and self restraint now in order to conserve their dwindling extra human resources and so turn to most use their inner resources of wisdom and generosity Though this is the conclusion of the matter, and gives only chastening comfort, it follows a well-organised factual account of what is happening and what must later happen if we continue in our present courses the account is objective and the main argument irrefutable

THE LANCET

Research in General Practice

There is a danger inherent in the work of general practice that the very great variety of subjects for practice and thought in a day's work may lead to a superficial and desultory curiosity rather than an eagerness for study

WHEN he offered this reflection in the first John Matheson Shaw lecture[1] of the Royal College of Physicians of Edinburgh last November, Prof JAMES MACKINTOSH was discussing the opportunities for research now opening before general practitioners. A Sassenach might have softened the blow with some reference to the fatigues of the family doctor's day, but Professor MACKINTOSH merely added that "it is easy to spread a thin layer of butter on the bread of idleness." This bracing approach has much to commend it, for some of the past attempts to get general practitioners to contribute to research have started hopefully but died of inanition. Too often self-chosen projects lose their charm for men working in isolation, especially during winter epidemics. Modern research is often done best by a team, and the College of General Practitioners[2] is surely right in encouraging group projects while at the same time offering information and help to the investigator who prefers to work alone.

At the end of 1954, the register of members willing to take part in research maintained by the research committee of the college council, contained some 380 names, sent in from every part of the Commonwealth. Research committees of 22 faculty boards have been formed in the British Isles and overseas composed of members and associates of the college and also coöpted members from local university or medical-school research departments. The college research advisory panel composed of experts in various medical fields, has been strengthened during the year. Scotland has its own research committee of the Scottish council with its own research advisory panel.

Four types of general practitioner research are being forwarded: college-sponsored investigations, studies by groups of doctors, faculty sponsored investigations, nd individual investigations. The college sponsored vestigations deal with subjects which can be studied ly in general practice, or studied there better than hospitals or laboratories.

A measles investigation to assess the value of sulphomides and antibiotics in preventing complications is ready in progress, and has only been handicapped (the port remarks sadly) by the low incidence of measles in 54. Better things are expected of 1955 and a report may published by the end of the year. A national morbidity rvey is being planned in collaboration with the egistrar-General's department; and a college records nit is being set up which should enable morbidity atistics to be recorded in a comparable way throughout e United Kingdom and overseas. Discussions with e Ministry of Health have resulted in the release of ational Health Service records of dead patients to ctors needing them for research purposes. It has en suggested that clinical trials of therapeutic substances might be made by general practitioners, but this introduces some ethical problems to which the college is rightly giving serious thought. Finally the epidemic observation unit of the college has coöperated with the Public Health Laboratory Service in collecting specimens from suspected cases of influenza for identification of the virus. Through this unit one member of the college has already brought to light an outbreak of Q fever in the South West; and specimens from a recent outbreak of infective hepatitis in the South East have been collected and studied.

Among the study-groups, one is engaged in observing the clinical patterns of acute respiratory infections; another, interested in hereditary diseases, is examining the incidence of hypertrophic pyloric stenosis in the children of people who have themselves survived Rammstedt's operation; a third group is investigating the value of tonsillectomy; a fourth interested in psychosomatic disorders, is making a study of asthma and migraine; and a fifth small group is concerned with *asthma in children*.

Faculty-sponsored investigations include one into obstetrical work in South West England; a study of the symmetry of heads of babies in Northern Ireland to determine whether cranial asymmetry is related to right handedness or left-handedness; a study, in Yorkshire, of the course of cancer in patients who for one reason or another have not been treated; and an epidemiological survey in South East England of non-notifiable diseases including glandular fever, infective hepatitis, and epidemic winter vomiting.

These studies have been started with great enthusiasm but the college has it in mind, from the history of earlier collective investigations, that too great a dispersal of effort may lead to disappointment, and moreover (Professor MACKINTOSH notwithstanding) that there is a limit to the amount of voluntary work a family doctor can undertake over and above his practice. They are therefore wisely planning rather to consolidate the research work begun than to expand into new fields during the coming year.

It is interesting to compare this promising beginning with the research programme Professor MACKINTOSH foresees for general practitioners in years to come. The Public Health Laboratory Service, as he points out, has greatly added to their powers to contribute to systematic research; and he hopes that before long a more organised system of diagnostic centres will be developed and take the place of the health centres—"which are now by general consent slipping back into the waters of Lethe." These, like the Nuffield diagnostic centre at Corby,[3] would be staffed by technicians working under the supervision of specialists, and here general practitioners would have direct access to technical help in the more straightforward types of bacteriology, radiology, and pathology—or could, if they wished, undertake laboratory procedures themselves.

First in his list of possible studies Professor MACKINTOSH puts hereditary defects and diseases, for family doctors, and especially old established firms of doctors have a better chance than most of noticing what happens from generation to generation. They can assess the significance of the eccentric relative and the slow child; can turn up records of stillbirths, neonatal deaths, minor congenital abnormalities, hæmophilia, Huntington's chorea, and pyloric stenosis; can observe the effects of common complaints on patients and their environment; and can assess the long-term effects of remedies old and new, and the protective value of vaccines. They alone have the chance of seeing the onset and full course of the diseases associated with old age, and can investigate both the basic and the precipitating causes of the so-called stress diseases They have remarkable opportunities, of which many of them make full use, of gaining skill in prognosis , and many a young doctor joining an old firm is startled out of his scientific calm by the uncanny skill of the senior partner in predicting the immediate and remote outcome of disease As Professor MACKINTOSH says, the true effects of pregnancy on chronic disease are largely unknown at specialist level Again, though the gross pathology of established disease can be seen and learned in hospital, the delicate innuendos of early disorder are to be apprehended only in general practice They are learned by watching the same patients for a lifetime Mental sickness, which sometimes has its origins in human relations, gives the general practitioner another field for study " The observation of years in a mental hospital or psychiatric clinic may not reveal as much about such patients in their true environment as the general practitioner learns in the course of his daily plodding " , and he it is, at present, who undertakes most of the follow-up and aftercare of patients who have been treated in mental hospitals Epidemiology still has many questions to be answered some incubation periods are still uncertain, and the modes of spread of many diseases are far from clear Professor MACKINTOSH notes the work in this field already being undertaken by the college, but mentions other possible inquiries—not only into the well-known infections such as chickenpox, herpes zoster, and poliomyelitis, but into local non-infectious diseases such as goitre and dental caries , and into chronic disorders such as rheumatism and bronchitis Finally, he suggests there is plenty still to study in the field of normal health and physiology—the disturbances of puberty and the menopause, the male climacteric, the onset of presbyopia, the significance of bodily and emotional types, and " the long fascinating story of child development "

[3] *Lancet* 1954, i, 871.

So much for the programme but there are, he hints, obstacles The first is the medical curriculum, which not only fails to prepare the student for research under the conditions of medical practice but introduces him mainly to the late stages of disease, gives him the scantiest notions of the relations of sickness to social and industrial life, and does not equip him with enough elementary statistics to conduct simple investigations in the field of general practice Given an early understanding of statistical methods and of the importance of controls he would quickly recognise how little is other apparatus needed for important work two eyes, a pen, and a record card often suffice Other obstacles are the want of liaison between general practitioners and consultants, the scarcity of leisure, the broken time, the prejudice of patients (" people in general have a respect almost amounting to awe for research, but they do not enjoy being the subjects of investigation themselves "), and the absence of a stimulating atmosphere, such as is found in hospital or laboratory But all these obstacles, he urges, can be overcome The college is already playing its proper part by giving help and guidance (particularly in the matter of collecting accurate statistics), by organising research teams and groups, and by keeping keen people [illegible] with one another and with experts in their subjects . Other incentives must come from elsewhere—from the medical schools, which must equip their students better for research , from the Ministry of Health, which can distribute information about minor disorders (bronchitis, common colds, and the neuroses) which are responsible for much ill health, and as a by-product from group practice which gives the doctor time for reading, writing attending clinical meetings, looking after his own health , and developing more fully his skill in his profession

Cell Type in Bronchial Carcinoma

NO-ONE would suggest that surgery is an adequate weapon in the treatment of bronchial carcinoma, but it is the best we have , and with modern technique roughly one quarter to one third of patients who have " curative " resections survive operation by at least five years[1–6] It is now clear that the prognosis in these cases is greatly influenced by the cell type of the tumour[5–8] Bronchial carcinoma is usually classified histologically as squamous cell, adenocarcinoma, or undifferentiated , but KIRKLIN et al[6] consider that it is worth subdividing the undifferentiated group into small cell carcinoma and large cell carcinoma The cells in small cell carcinoma have little cytoplasm, they are irregularly arranged, and as the nuclei are often spindle shaped the term " oat cell " is commonly applied to this group The cells in KIRKLIN's large-cell type have more cytoplasm, but the other histological features are variable, sometimes resembling those of the small cell variety and sometimes those of the squamous cell type, so that pathologists recognising only three groups would put them in one or other of these categories

The prognosis in the small-cell (oat-cell) type is very poor, though occasional good results are achieved On the other hand, the outlook in the squamous cell variety is relatively good[5–8] There is more doubt about the prospects with an adenocarcinoma, KIRKLIN and his colleagues,[6] for example, consider that the chances of a successful operation are almost as good as with a squamous cell tumour, whereas HOLMES SELLORS's experience[5] has been that the chances are not much better than in the deadly small cell group The prognosis in the large cell variety is poor, though it is apparently somewhat better than when the tumour is of the small cell type[6] Moreover, squamous-cell carcinoma means more than a better chance of survival after a " curative " operation, for a higher proportion of such growths are amenable to surgery when first diagnosed[6 8] , so that at first sight it seems fortunate that in most analyses of the results of treatment in bronchial carcinoma this variety is commonest But, as BIGNALL has lately pointed out,[9] it is the highly malignant small cell

tumour which preponderates in necropsy studies, and this discrepancy may be explained by the fact that it is the potentially operable cases which go to the special centres from which statistics of survival rates usually come

It is difficult to get reliable information about the actual proportion of all cases which are suitable for surgery when first diagnosed but it is safe to say that it is depressingly low Can the position be improved? Nothing can be done about the most decisive factor influencing survival—the cell type of the tumour—but there is a chance to reduce the delay between the appearance of symptoms and diagnosis Even so, it is doubtful whether any sizeable improvement in the situation would follow and experience so far suggests that mass radiography[9,10] has no striking contribution to make towards a reduction in mortality Indeed BIGNALL came to the sombre conclusion that, even with the most efficient medical service possible we could not, with present methods of diagnosis and treatment hope for any substantial improvement He suggests that we should aim at more effective palliative remedies and it is only necessary to consider the vast sum of human suffering involved to appreciate the value of any such advances

A Century of Army Pathology

THE story of pathology in the Army is one of small beginnings, big opportunities distinguished achievements, and heavy responsibilities faithfully discharged At the centenary of the service last week there was no lack of great names to honour or fine work to recall but above all there was a sense of this work continuing Nor is it limited or separate from work elsewhere Nowhere more than in pathology is there interchange between Army and civilian medicine, and the mixed gathering at the Royal Army Medical Corps Headquarter Mess on April 27 was evidence of a symbiosis which has been particularly happy and always beneficial

The day was chosen because it was on April 27, 1855 that Dr R S D LYONS, an Irish physician, and his "two able assistants" Dr WILLIAM AITKEN and Dr DOYLE, were sent their instructions on the pathological researches they were to undertake at Scutari among the sick and wounded of the Crimea In his centenary article on the service Major-General SACHS[11] quotes these instructions

> 4 As Morbid Anatomy is of little value unless studied in connection with the history of the disease You and your Assistants will require to visit the Hospital wards in order to become acquainted with the symptoms and characters of the diseases during their progress but you will not interfere with the treatment of the patients. In making notes of the cases, the name of the patient, and the number of his regiment should always be stated as by this means the nature of his duties, and the place where he was first attacked by disease can be more easily ascertained
>
> 6 It is expected that you will not content yourself with the simple dissection of the subject and the demonstration of the morbid parts, but that you will submit them to microscopical examination

Even at this early date in an era when little was known about the staining of tissues the importance of the microscope is usefully emphasised, and the instructions are well drawn. Less understanding was shown by the War Office when for years it blocked the plans made by FLORENCE NIGHTINGALE for a school of military hygiene and when at last, in August, 1860, the Practical Army Medical School was opened at Chatham the first 10 students found bare walls and no equipment Nevertheless it was not long before the school as the Army Medical College at Netley, redeemed its bad start Its professor of pathology from 1860 to 1892, Sir WILLIAM AITKEN F R.S , became the father of military pathology and was to make considerable contributions to medicine through his pupils Thus the roll of his assistant professors includes Surgeon Major TIMOTHY LEWIS (F R.S -elect when he died at 45) Sir DAVID BRUCE F.R.S and Sir DAVID SEMPLE. He was succeeded by Sir ALMROTH WRIGHT, F R.S who in 1903 when the college came from Netley to London was in turn succeeded by Sir WILLIAM LEISHMAN F.R.S In 1914 and again from 1919 to 1921 the chair was was held by Colonel S LYLE CUMMINS

In the decade preceding the first world war the value to the Army of a well-organised pathology service was gradually recognised, and the training of regular Army pathologists proceeded steadily, with research by teams as well as individuals The war saw the development of mobile bacteriological laboratories, hospital laboratories and research laboratories and classical work was done on wound sepsis tetanus, gas gangrene shock, and many forms of infectious disease The war also showed the need for a degree of central direction of all these vital undertakings, and in 1919 the Pathology Directorate was founded at the War Office with LEISHMAN as first director assisted by DAVID HARVEY and A C H GRAY At the same time the Army Pathology Advisory Committee came into being—a body to which Sir FREDERICK HARRIS director general of Army Medical Services paid a special tribute last week. (Among its original members was Dr MERVYN GORDON F R.S who attended every one of the seventy meetings during his lifetime) Under these arrangements development continued and research flourished especially in the 30s In India the pathology service profited greatly from the energy and drive of Major (now Major General) JOHN MANIFOLD Also in India, J S K. BOYD F R.S , made his observations on dysentery bacilli, and L T POOLE worked with H E SHORTT of the I.M.S on the virus of sandfly fever At the Royal Army Medical College MARRIAN PERRY was collaborating with H. T FINDLAY and H J BENSTED on virulent typhoid strains in the production of vaccines and BOYD investigated the dosage and administration of tetanus toxoid

In 1939 the Army had a well developed and efficient pathological service capable of rapid expansion Under the directorship of Major General PERRY, the formation of an Army Blood Transfusion Service was undertaken by Sir LIONEL WHITBY who with such lieutenants as G A H BUTTLE W D'A. MAYCOCK, and G T L. ARCHER made it one of the outstanding achievements of medicine in the war In 1941 Major General POOLE succeeding PERRY as director of pathology, took over a task now made immensely intricate by the requirements of large Forces in widely separate theatres of war and by the need to arrange and assist many kinds of urgent research by

many different kinds of group How well that task was performed, by him and his assistant Lieut-Colonel BENSTED, is known to many colleagues in all departments of medicine, who were thankful for his combination of high standards with a receptive mind and readiness to help After his retirement in 1945, the directorship was filled, for shorter periods, by Brigadier BOYD, by Brigadier FINDLAY, and by Major-General SACHS, from whose lecture at the college on April 27 we have drawn many of the facts of this outline Since 1953 the director has been Brigadier ARCHER, who arranged this memorable commemoration and at last week's dinner gave what he called the primary response to the toast of the Army Pathology Service proposed by Sir LIONEL WHITBY This is a toast with which a great many people have reason to associate themselves—even though they may never have heard of the service

Annotations

POLIOMYELITIS VACCINATION

MISGIVINGS about the new poliomyelitis vaccine,[1] lately put into extensive use in the United States, have been aggravated by last week's news that a number of children have fallen ill with paralytic poliomyelitis shortly after vaccination It is reported that 35 children have had paralytic poliomyelitis within a short time of vaccination,[2] and 2 have died Almost all these children had been injected with vaccine prepared by the Cutter Laboratories, of Berkeley, California, and supplies from this manufacturer have been recalled In the States of Idaho and California the immunisation programme has been stopped for the time being In Washington the situation has been examined by a group of advisers, including Dr Salk, and they have recommended that inoculations should continue[3] About 4 million people, nearly all children, have so far had a first injection In this country the Medical Research Council decided on Monday that their trials would not start until fuller reports of the American results were available

There are three possible explanations of what has happened First, the children may have been going to get poliomyelitis anyway, and vaccination was too late to have any preventive action Second, the children may have been carriers of poliomyelitis virus, and vaccination acted as a provoking stimulus in a similar way to pertussis and diphtheria immunisation Third, the vaccine may have contained live virus At present there is not enough evidence to decide which explanation is correct, but the third seems the most likely As there is nothing definite to suggest that vaccine manufactured by other laboratories is liable to produce paralytic poliomyelitis, it may be that the virus in certain batches of the Cutter vaccine had been incompletely inactivated

If it should turn out that the vaccine contained live virus two important questions must be considered. Did the Cutter laboratories follow closely the technique of inactivation by formaldehyde recommended by Salk? It seems unlikely that any firm would knowingly vary the procedure, and if these methods were in fact closely followed the margin of safety of this technique should be re examined In particular, there should be a thorough scrutiny, in a number of different laboratories, of the kinetics of inactivation of all three types of poliomyelitis virus by formaldehyde under various conditions The second question concerns the tests of safety which were applied to this particular vaccine Previously, vaccine had been tested to exclude the presence of live virus by tissue-culture techniques and by intracerebral inoculation of monkeys If the tests carried out on the suspect vaccine were not as rigorous as those applied during last year's vaccination trial, the remedy seems clear Many thousands of children received the Cutter vaccine, so the relatively small number of cases of paralytic poliomyelitis may mean that only a few infective virus particles remained in the vaccine On the other hand, if the vaccine passes the safety tests but is still suspect on the grounds of a statistical analysis of the incidence of poliomyelitis following its use, then we must think again about the safety tests Is it wise to apply the results of tests with scores of monkeys to the vaccination of hundreds of thousands of children? We hope that it will not be necessary to make these further inquiries, and that the postvaccination cases may turn out to be unrelated to the vaccine But at the moment it seems unlikely that the vaccine will escape all blame

ANÆSTHESIA IN OBSTETRICS

THE advances in anæsthesia in the past few years have usually been accompanied by administrative steps which have made the new techniques available to almost every patient who has to have an operation in this country But this scarcely applies to anæsthesia in obstetrics, and there are good reasons to reconsider the position in this branch of anæsthesia, as was done at a meeting of the section of obstetrics and gynæcology of the Royal Society of Medicine on April 22

There has been some uneasiness about an apparent increase in maternal deaths due to anæsthesia, but this may well be only a relative increase, brought about by a fall in the number of deaths from other causes One danger lies in giving general anæsthesia to a patient who has not been properly prepared for it, the mother is sometimes given food and drink almost up to the last moment, and there is occasionally, after prolonged labour, a gastric atony and a stomach full of fluid, which can remind the anæsthetist of paralytic ileus or intestinal obstruction Again, these anæsthetics are not always given by those thoroughly familiar with the drugs they are using, or with the particular points on which to concentrate during the administration Where anæsthetics are given to mothers in labour, suction apparatus should be close by, and the delivery table should be one which will tip both head up and head down. The head-up position, with the use of a relaxant drug and the passage of a cuffed endotracheal tube, is perhaps the safest method in experienced hands Sometimes induction at least should be carried out in the lateral position

The dangers of general anæsthesia emphasise the case for local or regional analgesia whenever possible. General anæsthetics are essential from time to time, for intra-uterine manipulations such as internal version and manual removal of a retained placenta, but the occasions could perhaps be chosen more carefully General anæsthesia is often adopted without question because it allows every conceivable procedure to be carried out, but in many cases another and safer method might have been equally effective Local and regional blocks have difficulties and dangers of their own, but there are many impressive reports of series in which they have been successfully used Perineal field block is probably the safest for mother and baby properly carried out, it will permit low, possibly mid-cavity, forceps delivery and it is particularly suitable for breech delivery As for domiciliary operations, modern antenatal care has made a high proportion of them straightforward, but the same dangers can threaten At the meeting at the Royal Society of Medicine last month, Dr R B Parker gave statistics from Birmingham which showed that the risk of maternal anæsthetic death was greater in hospital dice than in domiciliary obstetrics The domiciliary thetic is almost always chloroform, with or without The dangers of chloroform are well known and se is sharply condemned on all sides; but many mourn the passing of chloroform from hospital tice, and miss the smooth induction and the bility it affords At present there is nothing which replaces it for those who give most of the anæs ics in hospital obstetrics

seems that there is much useful information to be ined from a wide survey of anæsthetic mortality morbidity in obstetrics, both domiciliary and itutional This should take into account the circum ces of the operation the equipment available (such ipping bed and suction apparatus) and the experience training of the anæsthetist

XERORADIOGRAPHY

is a new form of X ray photography xeroradiography wet chemicals are used to develop the latent photo phic image The process is a photo electric one and s first described by Carlson in 1937 Although it has en in use in commercial photography for some time, edical applications are only now being investigated. e technique depends on the property of a group of bstances, known as semi-conductors, to hold an elec ical charge in the dark but to allow it to leak away when posed to light or X rays Of these substances the ost promising so far investigated is amorphous selenium xerographic plate consists of a metal base on which is posited a layer of selenium 120–150 µ thick. It is otected from light and mechanical damage by a cover milar to an ordinary photographic cassette Before e the plate is charged in a special chamber by a high ltage D C. source, which gives the selenium a positive ectrostatic charge The plate is exposed in the normal ay and the image is developed by spraying a fine wder on the surface of the plate in another light oof chamber The powder is taken up by the surface the plate according to the amount of charge remaining d so an image appears It takes about 10 seconds to arge the plate and about 20 seconds to powder it diographically speaking these times are remarkably ort even compared with those possible by the rapid t processing methods now available and there is the ded advantage that no dark room is required. Indeed whole charging and powdering equipment can be ilt into a trolley 4 ft by 2 ft or less and tucked into any ner of the X ray room or operating theatre Costs problematical but the charging and powdering chine may cost from £200 to £500 and the plates about each and since these can be re used indefinitely the thod offers a cheerful prospect of reducing costs

The quality of the image is a more debatable point. The rograph is rather like an etching in black and white d it is viewed by reflected light To the unaccustomed at least it is more difficult to interpret than e conventional radiograph. The image is of low ntrast, and soft tissue and bones are easily distinguish le on the same plate The powder tends to build up lines along the margins of the more dense parts of the age and this enhances the contrast and the clarity detail Fine wire grids as close as 1200 to the inch can resolved whereas, with normal film detail deteriorates 180 lines per inch[1] At the present stage of develop nt the speed of the xerograph is not all it might be ing about the same as that of non screen film; posures are therefore unacceptably long for the heavier rts of the body Another disadvantage is that a rmanent record can be made only by photographing e xerograph on miniature film or by copying it electri lly; this would be a particular drawback when a ries of radiographs has to be inspected regularly or hen it is likely that one or more films will be needed for future reference Further research into the possibility of using a translucent base, to allow inspection by trans mitted light, and of reducing the exposure required may make the method more useful medically

Much of the work on xeroradiography has been done in this country by W D Oliphant in Edinburgh, and trials of the equipment are well under way From America it is depressing to learn that the method is being considered as a means of replacing stocks of ordinary film fogged by atomic explosions But more cheerful news of the interesting medical possibilities should be coming shortly

SECOND AID

THE treatment of an injury begins almost as soon as it is sustained The patient himself—or a witness who renders assistance or tenders advice—is his first " doctor " From this haphazard beginning he passes through the hands of successively more experienced helpers until he undergoes definitive treatment His progress may involve a parent an older workmate, a resourceful bystander, a civilian or policeman trained in first aid, the chemist,' a nurse, a doctor a hospital and perhaps ultimately a specialist in traumatic surgery or a team of specialists The more serious his injury the more likely he is to follow this sequence to its end but how far he travels along the line depends also partly on chance and partly on the organisation Many of those who get no further than one of the early stages might have profited if they had been carried at least one stage further There is still much avoidable disability because patients with trivial injuries are not brought to clinics and services which are there to treat them until some complication has set in Of those sent to hospitals well fitted to deal with them some have suffered by delay in the preliminary " filter ing some by well meaning but unenlightened handling on the way, and some because no one appreciated that a patient with a dangerous condition may not look dangerously ill

One particular section of this line is receiving increasing attention, as is well illustrated by two publications from the committee on trauma of the American College of Surgeons[1 2] One is the fifth edition of a monograph on the treatment of fractures the other a new companion to it, is a similar work on the early care of soft tissue injuries The growing realisation of the importance of this second type of injury is reflected in the size of the monograph on it, which is twice that of the other Both combine simplicity brevity and absence of distracting controversy with remarkable comprehensiveness. Both may be accepted as a concise presentation of the most authoritative views in contemporary American teaching Both emphasise the value—often the supreme value—of correct *early* treatment which may lie in the hands of younger and comparatively inexperienced people They are aimed at interns and residents in the hospital who serve their periods in the emergency room " and at all doctors who have to do with the treatment of injuries but there is sufficient indication of the later specialised treatment for readers to understand why initial decisions have a vital influence on the final result

It is neither possible nor desirable for every minor injury to be submitted to highly specialised services. Nevertheless much delay in recovery may be avoided if those responsible for early care are guided to select accurately the more serious injuries and if they are briefed on the best way to deal with these before they are sent on Senior surgeons cannot sit all day in their casualty departments waiting for the next accident but they can make clear their wishes on early treatment and they can inform their juniors of the type of surgery likely to be required later in the day House-surgeons casualty officers, and "interns" usually have a comparatively brief term of office Many casualty departments and accident rooms have a periodicity in the standard of their service which corresponds with the length of the doctor's appointment Continuity of policy among successive holders is difficult to maintain, and these publications could do much to maintain it

ANTI-HISTAMINES AS HYPNOTICS

MANY anti histamine drugs in common use cause drowsiness, and that is usually unwelcome, but Straus et al ,[1] in New York, have tried to decide whether this property can be turned to good account In a controlled experiment they have shown that the anti histamine, methapyrilene hydrochloride, in a dose of 50 mg by mouth, is as effective a hypnotic as 100 mg (gr 1½) of phenobarbitone This work confirms a general clinical impression, but anti-histamine drugs are unlikely to be widely accepted as alternative hypnotics to barbiturates

The experiment is of interest because of the methods employed in evaluating methapyrilene's hypnotic powers It was conducted on the "double-blind" principle, and methapyrilene was compared with a positive control (in this case phenobarbitone) and with a negative control (an inert capsule) The "cross over" technique was used—that is, all patients received all the substances being tested, but different sequences were followed in the various patients The choice of phenobarbitone as a positive control was perhaps unfortunate, for this drug is usually classed as a sedative rather than a hypnotic, and 200 mg (gr 3) of pentobarbitone would perhaps have been a better dose The greatest difficulty in an experiment of this kind is the selection of suitable patients Ideally (for unquestionable results), no one should sleep well after the placebo and all should sleep well after the positive control As the experiment was designed with an evaluation period of three weeks, it was necessary to select patients with chronic insomnia relatively uninfluenced by factors other than the change of medication Obviously the ideal conditions will rarely be obtained in practice, and, in fact, although Straus et al selected their 54 subjects with great care (only male patients were included), 30% showed an excellent response to the placebo The number of variables might have been less if each drug had been given only once to each patient, and if a larger number of patients had been used

The criteria of a night's sleep were the patients' own statements in a standard interview and the observations of a night nurse who shone a flashlight on each patient regularly during the night The nurse's impression of the patient's sleep was consistently better than that of the patient himself Other methods of measuring sleep, notably electro encephalography, were considered but all were rejected as inferior to the simpler tests employed Each night's sleep was classified and scored, and the data so obtained were statistically analysed in considerable detail The conclusion was that, as a hypnotic, methapyrilene was superior to the placebo and about equal to phenobarbitone The refinement of the statistical methods seems scarcely suited to the analysis of data measured on an arbitrary scale, and in the presence of many uncontrolled and often unidentifiable variables But Straus and his colleagues have given a very good example of a carefully designed experiment, and it would be a great advance if all new hypnotics were examined with equal care On the other hand, some may think that the information obtained by an elaborate study like this still falls short of scientific proof, and that the judgment of an experienced clinician, based on the observation of relatively few patients (and perhaps of himself on the night train to Scotland), is still a very good measure of what a hypnotic is really worth

ORTHOSTATIC PROTEINURIA

ORTHOSTATIC proteinuria is a condition in which th urine is normal while the patient is lying down, b contains protein when he is up and about It is usual considered to be a temporary and harmless anomal King,[1] in a study of 4000 cases of proteinuria in th United States army, has put forward the view that i is often permanent and not completely benign Th proteinuria persisted for three years in 131 of 170 cas and many of these gave a history of proteinuria for u to ten years previously These observations agree wi those of Thorp and Wakefield [2] who found that 43 o 64 patients still had proteinuria after six years Th incidence of anatomical abnormalities of the kidneys an ureters in cases of orthostatic proteinuria is unusual high King found that 18 of 56 cases showed rad logical abnormalities by intravenous pyelography, a Young et al [3] have reported a similar proportion

The amount of protein lost in the urine may occas ally be as great as in severe glomerulonephritis. Co centrations of protein as high as 4 g per 100 ml in sin urine specimens have been reported,[4] and Wolman states that the range of concentration in 24 hour spe mens is 15–545 mg per 100 ml, with a mean value o 74 mg per 100 ml The highest level corresponds to protein loss of about 8 g daily, equalling that found i many examples of the nephrotic syndrome Elect phoresis showed that the proportion of globulin w unusually high [1]

There is still controversy about the cause of th condition Sonne [6] considered it was the result of c pression of the left renal vein as it crossed the abdom aorta, and Bull [7] thought that rotation of the li during lordosis compressed the inferior vena cava a so increased caval venous pressure King believes th further experimental evidence is necessary before eith of these hypotheses can be accepted King and Baldw have confirmed Bull's finding [7] that there is a profou fall in glomerular filtration rate and renal plasma-f in the erect lordotic posture, but they found no signific difference in filtration rate or plasma flow when c of orthostatic proteinuria were compared with n proteinuric controls

The immediate prognosis in cases of ortho proteinuria is good, and it is certain that this anom does not indicate rapidly progressive renal dis Insurance statistics suggest, however, that the mortal over many years is significantly greater than in cont "good life" cases Daley [9] states that actuarial statis published in 1938 showed a mortality in 52,000 cases "intermittent" proteinuria of 128% of the expect level Further experience [1] up to 1951 suggests t the mortality rises to 150% of the expected figure that the extra deaths are most commonly due cardiovascular disease

THE next session of the General Medical Council open on Tuesday, May 24, at 2 P M, when Sir Da CAMPBELL, the president, will deliver an address. T Medical Disciplinary Committee will meet on Thursd May 26, at 10 30 A M

Prof G W CORNER of Baltimore has been elected foreign member of the Royal Society in recognition his work on the endocrine control of gestation especially on the function of the corpus luteum mammals

Special Articles

CANCER

THE PSYCHOLOGICAL DISEASE

MALCOLM DONALDSON
FRCS FRCOG
IRECTOR OF CANCER SURVEY YORKSHIRE COUNCIL, BRITISH
EMPIRE CANCER CAMPAIGN

THE title of this article is not intended to suggest hat cancer is a 'psychosomatic' disease but rather o point out that besides the physical disease of cancer here is a psychological condition of 'cancer appre ension,' which affects almost the whole population his mental attitude is present in many members of the edical profession although in their case it assumes rather different form and the fact that discussions n cancer education often generate more heat than rguments about politics or even religion, may in itself e additional proof of my thesis.

PREVALENCE

Is this apprehension of direct harm to the community? learly in its acute form of 'cancerphobia' it causes eat harm to some individuals and each year a few icides are recorded, where the unfortunate victim found to be without trace of the disease Mental orry even if only intermittent as is often the case in ncer apprehension must also be harmful to the indi dual, and, if widespread, must surely be bad for the mmunity What evidence is there that cancer appre nsion is widespread? There is no statistical evidence t surveys in America are suggestive and a survey mong 1200 Manchester women[1] showed that three-arters considered it the most alarming of all diseases

Every doctor has patients who visit him with vague mptoms, and if at the end of an examination the ctor says 'I am glad to say that I can find nothing ious, no evidence of tumour or cancer' as often not the patient will say "Thank God, that was what was really worried about" Such cases clearly indicate e presence of cancer apprehension Unfortunately ne of these cancer-apprehensive patients are not ognised they are labelled neurotics or neurasthenics d they continue to live on the doctor's doorstep in the pe of being reassured

Reluctance in the dislike to mention the word cancer also evidence of apprehension Obituary notices er to a 'long and painful illness bravely borne eart-disease with its greater mortality is never nned in this way) Doctors even if they are not xious about themselves are anxious that nobody ould hear or think about cancer Whether a tient should be told the truth must depend on circum nces. Often the relatives are told but the patient deceived—if he or she can be deceived which is doubtful ter if the relatives think they have cancer the doctor ds it hard to convince them that there is no cancer the Manchester survey already mentioned 40% of e women thought that the patient should be told y attempt to keep the disease 'hush hush' must d, because it is met with so frequently Each year in this ntry about half a million are added to the number people who have already come in direct contact th a patient

An incident illustrating the fatalistic and defeatist titude of some doctors towards cancer happened to e When I entered hospital to be investigated for a ssible gastric carcinoma one of my colleagues said Of course you know you have not got a carcinoma you would never go into hospital On leaving hos tal after an exploratory laparotomy which fortunately oved negative another colleague said 'Of course you were the only person who thought it might be carcinoma Would these remarks have been made about any other disease?

Though there may be a difference in opinion as to how widespread is cancer apprehension there is no doubt that it often delays diagnosis There are no figures to show how many patients put off a visit to the doctor for fear that the condition may be cancer but the answers given in the Manchester survey to the question why women are more frightened of getting cancer than any other disease, are probably also the reasons for delay in reporting symptoms to a doctor Of these the answers that it is 'fatal' 'incurable' 'gets worse' 'only know when it is too late,' and "because of the pain and suffering" head the list

There are figures, however which show the time that elapses after a patient has noticed a symptom before he or she seeks advice Stocks[*] reported that the median number of months interval between the earliest symptom and the start of treatment for cancer of the uterus was 5 7 months (taken from the figures supplied by twenty six hospitals), for the breast 6 months and for the rectum 5 6 months Figures collected by the Yorkshire council of the British Empire Cancer Campaign show much the same delay

TREATMENT

What can be done to lessen apprehension and thus obtain earlier diagnosis? Surely the answer can only be to educate the public by giving information about the accessible cancers and by encouraging people to talk about cancer, and thus to bring their fear to the surface and to face it Those who oppose this plan do so chiefly on the grounds that attempts to educate the public will increase cancer apprehension and fear If true this would certainly defeat the object of obtaining earlier diagnosis Psychiatrists could help us to settle this question, but unfortunately, though interested in the treatment of true 'cancerphobia' patients they have little time to study the problem.

The Yorkshire Council of the B E C C, with the help of some of the local health authorities in the area, have lately given 220 lectures to the public on cancer educa tion At the end of most of these a printed slip is passed to each member of the audience asking whether the lecture has increased their worry and such lectures should not be given or whether it has diminished their worry and more lectures should be given The results from 5740 votes shows 99 1% in favour 0·2% against while 0·7% put a question mark

The other argument used against cancer education is that even if patients are persuaded to visit their doctor when a symptom is noticed the number of cancers treated in the early stage will not be greatly increased because of the large number of growths that disseminate before giving rise to symptoms It is very doubtful whether this is true of the accessible cancers which are the only ones that cancer education can hope to benefit

Figures quoted in support of this are usually based on the results of treatment within six months of noticing symptoms and after six months This is, in fact a comparison between two different types of growth The first set of figures includes all the rapidly growing tumours as well as the slow growing well-differentiated tumours whereas the second set includes only the well differentiated, slow growing ones The figures needed are those for 0–1 month 1–2 months 2–3 months &c., for the accessible cancers In the Manchester survey 76% agreed that there should be freer public discussion of the symptoms

If the psychiatrists could confirm the psychological benefit of cancer education it would be a great help to those of us who are trying to obtain earlier diagnosis

WORK OF A GERIATRIC UNIT

A SURVEY OF 13,500 PATIENTS

KENNETH B GIBSON
M.B E , M D Lpool, M.R C P
LATE PHYSICIAN SUPERINTENDENT, NEWSHAM GENERAL HOSPITAL, LIVERPOOL

I HAVE recently completed a survey of all inpatients treated in the 18 medical geriatric wards of this hospital, from the beginning of 1950 to the end of June, 1954 Of these 13,500 patients, 11,000 were over sixty years of age, and some of the findings seem likely to interest others concerned with planning hospital care for the elderly

The Background

Newsham, like many of the country's larger hospitals, had a humble origin as a 19th-century poor-law institution As time went on, buildings designed as dormitories for the able-bodied gradually came to be used as wards for the growing number of infirm inmates The occupants of these wards were mostly old and bedfast Some were merely frail and homeless, some were disabled by chronic disease, some were acutely ill For several decades there were few facilities for medical investigation, treatment, or rehabilitation , but a high standard of nursing care, provided by a hard-working though largely untrained staff, tended to conceal the defects of the system These defects were aggravated and became more conspicuous during the second world war, when a depleted staff had to meet the additional demands of the Emergency Medical Service Its new rôle as an emergency hospital led to the appointment of its first two resident medical officers, but the war precluded any large scale improvement

In 1946 there began a phase of development which has continued ever since, with a minimum of interruption due to the change of management in 1948 Staff was augmented , equipment was provided , and, despite financial restrictions and material shortages, some modest but useful structural alterations have been achieved The original programme for the modernisation of the hospital's 34 wards is now nearly complete, and ancillary services have been steadily expanded to meet the increasing demand for investigation and rehabilitation of a medical staff which now numbers 36 At the beginning of the period of this survey there were already adequate facilities for radiology, pathology, physio therapy, and occupational therapy , and an almoner's department dealt with social problems By the end, all these departments had been further improved and ma new ventures had been started—e g , there was a chirop dist, a dispensing optician, and a cardiographer, t hospital had its first operating-theatre , and a sm follow-up clinic had been set going

The number of beds in medical geriatric wards inev ably fluctuated during four and a half years, and th over all result was a slight reduction from about 740 i 1950 to 707 in 1954 For instance, 16 beds were lo when part of a male ward was converted to enlarge th X-ray department ; others were sacrificed to mu needed sanitary improvements in several wards In t review I have excluded 2 wards for senile dement a 1 mixed psychiatric ward Also I have ignored int departmental transfers , but this two way traffic is to small to influence the main findings

Most of the patients in the survey were admitted a the request of their own general practitioners Dur the greater part of each year there is a waiting list, a patients are admitted in their turn unless their doct ask for priority Apart from an occasional need to a the relative urgency of claims for priority, there was n selection or screening of admissions by the hospit medical staff About 9–10% of each year's admissi were transfers from hostels and other hospitals

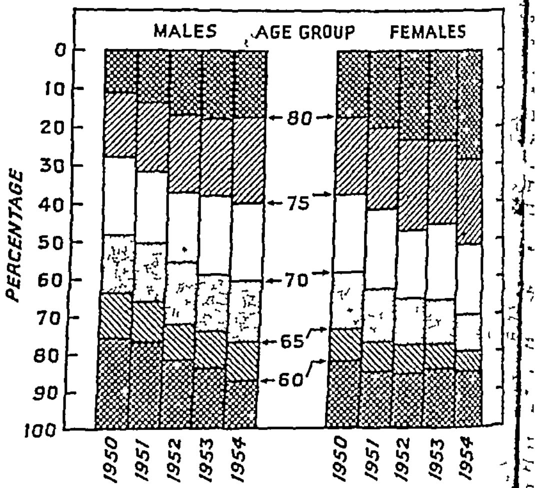

Fig 2—The changing age-distribution of men and women admit geriatric wards in 1950–54 (1954 percentages based on adm during the first six months of the year)

The 18 wards included in the survey form a compo geriatric unit, which undertakes not only investigati treatment, and rehabilitation, but also the long te care of patients with chronic disease who cannot adequately nursed outside hospital The latter are segregated in a separate annexe In general, a wa or group of wards, retains its own long stay pati but tends to concentrate them as a matter of conveni This system is largely dictated by local conditions offers many advantages Both medical and nursing share the variety and interest of different types of wo and most elderly patients like to remain with the s staff throughout their stay Moreover, the atmosph of an active ward helps to sustain an expectation ultimate discharge in the minds both of patients their relatives

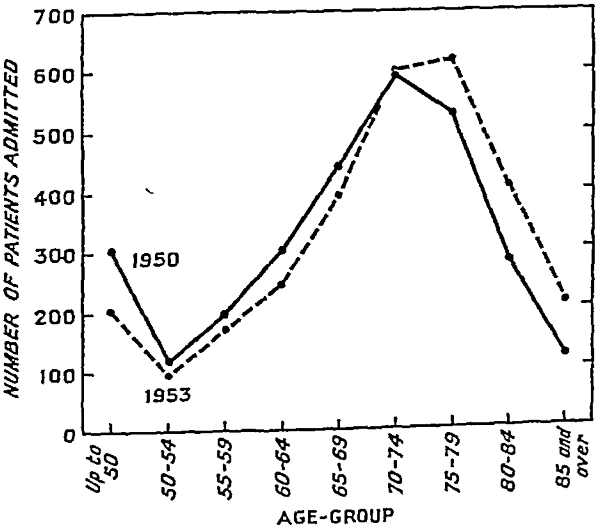

Fig 1 [illegible] of the ages of patients admitted in 1950 and 1953.

Analysis of Results

Age of Patients

Patients over seventy years age of increased fr 1516 (52 8% of all admissions) in 1950 to 1822 (6 in 1953, and represented 65 2% of all patients adm in the first six months of 1954 Higher in the age-s the proportion of admissions over eighty years of a increased from 13 9% in 1950 to 23 2% in 1953 (fig 1

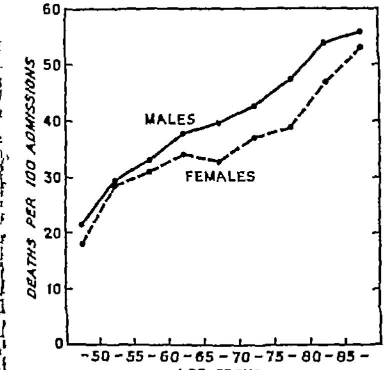

Fig. 3—Mortality of whole series at different ages.

Like other geriatric units (Thomson 1949, Morton 1952, Amulree et al. 1952, Andrews and Wilson 1953) we found that men tend to be admitted at an earlier age than women (fig. 2). In both sexes the age on admission rose in successive years, but women showed a greater increase than men. The increasing proportion of men in the older age groups depended partly on a reduction in the proportion under sixty years of age, while the numbers of women under sixty varied very little.

Mortality

As in the general population, mortality increased with age after fifty years, and in every age group women had a lower mortality than men (fig. 3). Death rates per 100 admissions varied from 18·0 (women under fifty) to 55·4 (men aged eighty five and over); the death rate did not pass the 50% level until age eighty for men and eighty five for women.

Despite the increasing age of patients admitted, mortality rates fell during 1950–53. Annual rates per 100 admissions (table I) are convenient for comparison, though not all the patients dying in a given year were admitted in that year. The mortality of both sexes combined shows a fall in each year after 1950, with the exception of 1951. (This interruption of the downward trend seems to have been caused by a severe influenza epidemic in January and February of that year. Mortality in this epidemic was particularly high in the elderly, and the hospital is situated in an area which was badly affected.) But table II shows that the combined mortality rates conceal an important sex difference. The over-all decline in mortality depends entirely on a fall in female rates (from 38·2% in 1950 to 33·4% in 1953), which offset a smaller rise in the male rates (from 39·5% in 1950 to 42·8% in 1953). The general increase in male mortality depends almost entirely on younger patients, however, for in the death rates of men aged sixty and over the rise is less definite. An unexpected finding was that both sexes had a falling mortality in the seventy-five and over age group. For this group the death rates per 100 admissions were:

TABLE I—MORTALITY IN GERIATRIC WARDS, 1950–53

Year	Patients of all ages			Patients aged 60 and over		
	Admissions	Deaths	Death rate	Admissions	Deaths	Death rate
1950	2877	1121	39·0	2256	963	42·6
1951	3216	1301	40·5	2587	1136	43·9
1952	3017	1166	38·6	[illegible]	1034	41·0
1953	2922	1109	37·9	2450	995	40·6

	1950	*1951*	*1952*	*1953*
Men	50·5	48·0	50·3	50·1
Women	48·5	47·0	41·5	39·5

Turnover

The highest annual total of admissions was 3216 in the year 1951—an increase of 339 over 1950. Rather more than half this increase in turnover can reasonably be attributed to the influenza epidemic, for in 1951 there were 173 more discharges as well as 180 more deaths than in 1950. Admissions then declined to 3017 in 1952, and again to 2922 in 1953. Even in 1953, however, admissions and discharges remained higher than in 1950, and the downward trend appears to have been checked in 1954, for 1523 patients were admitted in the first six months of that year.

The decline in turnover between 1951 and 1953—a difference of 294 admissions—certainly cannot be explained by the small reduction in beds already mentioned; for a loss of 24 beds would account, at 1953 rates of turnover, for 138 admissions at most. But this type of calculation over-simplifies a controversial issue. On the one hand, some of the improvements obtained in exchange for lost beds might be expected indirectly to increase turnover. On the other hand, any reduction in beds will tend to reduce admissions, and improvements, while they may at once increase comfort or convenience, will not increase turnover until this deficit is made good.

TABLE II—COMPARATIVE MORTALITY OF MEN AND WOMEN PATIENTS

Sex	Year	Patients of all ages			Patients aged 60 and over		
		Admissions	Deaths	Death rate	Admissions	Deaths	Death rate
Men	1950	1588	628	39·5	1200	534	44·5
	1951	1716	696	40·6	1316	596	45·3
	1952	1516	617	40·7	1238	538	43·5
	1953	1418	607	42·8	1187	536	45·2
Women	1950	1289	493	38·2	1056	429	40·6
	1951	1500	605	40·3	1271	540	42·5
	1952	1501	549	36·6	1284	496	38·6
	1953	1504	502	33·4	[illegible]	459	36·3

Table III suggests that the decline in admissions during these years depends mainly on falling mortality. The decrease in deaths was almost twice as great as that in discharges; moreover, if each is expressed as a rate per 100 admissions, the death rate fell by 2·6% while the discharge rate increased by 2·3%.

These findings illustrate an unpalatable truth—and a growing problem. Not every patient whose life is saved in a geriatric unit can be discharged, and falling mortality is likely to reduce the number of patients who can be served by each geriatric bed.

The numbers of discharges quoted above include patients transferred to hostels and other hospitals. In 1951, 337 were transferred, but in 1953 only 266, and their corresponding rate per 100 admissions fell from 10·5 to 9·1%. In the same period, patients discharged to their own homes showed a smaller reduction in actual

TABLE III—TURNOVER

Year	Admissions	Discharges		Deaths	
		Numbers	Rate	Numbers	Rate
1951	3216	[illegible]	59·9	1301	40·5
1952	3017	[illegible]	61·4	1166	38·6
1953	[illegible]	1817	62·2	1109	37·9
Difference 1951–53	−294	−108	+2·3	−192	−2·6

TABLE IV—TRANSFERS AND DISCHARGES

—	1951	1953	Difference
Transferred—			
to other hospitals	81	49	32
to hostels	256	217	39
Total transfers	337 (*10 5%*)	266 (*9 1%*)	71 (*−1 4%*)
Discharged to own homes	1588 (*49 4%*)	1551 (*53 0%*)	37 (*+3 6%*)

numbers and their rate per 100 admissions rose from 49 4 to 53 0% (table IV)

The fall in the transfers to other hospitals presumably reflects the development of Newsham and its growing independence of outside facilities The reason for the fall in transfers to hostels is more complex The number of places in local hostels for the elderly has increased in recent years, yet competition for vacancies seems to increase The turnover in the geriatric wards could probably be slightly higher if there were more hostel vacancies But the main problem arises from patients who, even after all possible active treatment, cannot be discharged to their own homes and are too frail to be transferred to most hostels of existing types It is an encouraging sign for the future that locally, at least, the need for a more sheltered type of hostel is recognised, and the hospital is collaborating with both the Liverpool public-health department and the Liverpool Personal Service Society to augment " half-way " accommodation for " frail ambulants "

Length of Stay

The study of length of stay in geriatric wards is complicated by a few patients who remain for long periods and whose final length of stay was still unknown when this survey was made For example, 56 patients admitted in 1949 or earlier, and a further 23 admitted in 1950, still occupied geriatric beds at the end of 1953 I have therefore divided all admissions into two groups —long term patients who stayed over twelve months, and those who left hospital within this arbitrary limit of twelve months According to this classification, 2 5% of the men, 5 2% of the women, and 3 8% of both sexes admitted in 1950–52 were long-term patients The proportion of each sex increased with age, and in every age group women show a higher proportion than men (table v)

TABLE V—PATIENTS ADMITTED 1950–52 WITH LENGTH OF STAY EXCEEDING TWELVE MONTHS

Age	Men	Women	Total
Under 60	15 (*1 4%*)	23 (*3 4%*)	38 (*2 2%*)
60–69	31 (*2 4%*)	36 (*3 8%*)	67 (*3 0%*)
70–79	52 (*2 9%*)	91 (*5 1%*)	143 (*4 0%*)
80 and over	22 (*3 3%*)	74 (*8 4%*)	96 (*6 2%*)
Total all ages	120 (*2 5%*)	224 (*5 2%*)	344 (*3 8%*)
Total 60 and over	*105 (2 8%)*	*201 (5 6%)*	*306 (4 2%)*

Fig 4 shows the proportion of long-term patients of different ages in 1950, 1951, and 1952 Though the proportion to total admissions remains about the same, there is a gratifying fall in the numbers and proportion of patients of seventy-five and over staying longer than twelve months

Admitted in 1950	63 patients (*7 0%*)
" " 1951	60 " (*5 1%*)
" " 1952	50 " (*4 0%*)

Choosing 1951 as an example, and excluding all long-term patients admitted in that year (4 1% of total), I have shown in fig 5 the mean duration of stay of all other patients—i e , those who left the unit within twelve months In this group, again, there is a remarkably close correlation between age and length of stay Both sexes show a steadily increasing length of stay in cessive age groups, but in every group the average of women was longer than that of men These patients also provide information about the effect on turnover of changes in mortality In each sex the average stay before death was much shorter than that before discharge (table vi)

A few of the patients admitted in each year of the survey are still in hospital, and it is not yet known to what extent they will influence the average stay of their group As an example of the serious distortion of average values which can be caused by a small minority of long stay patients, table vii shows the average stay of long term and other patients who left the unit in 19 Of the 3226 patients who died or were discharged, 31 had an individual stay of less than twelve months and the average stay was 47 days, while 121 long-term patients had stayed for an average of 970 days, or more than two and a half years A minority of 3 8% long-term patients raised the average stay of the 96 2% majority from 47 days to 81 days, and accounted for nearly 45% of the quarter million patient days spent in hospital by the whole group

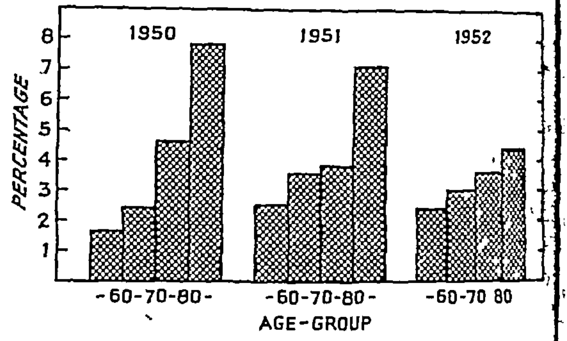

Fig 4—Proportion of each year's admissions with a stay exceeding twelve months, 1950–52.

Use of Beds

An important group of long term patients fails to qualify for inclusion in the usual statistics of admissions, discharges, and deaths in any one year In 1950, for example, 187 beds were occupied throughout the year by patients who were admitted before Jan 1 and remained on Dec 31 The number of beds occupied throughout a whole year fell to 170 in 1951, but rose

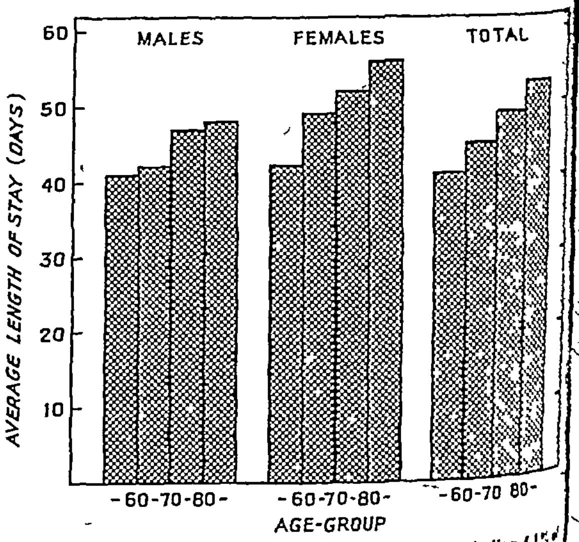

Fig 5—Average stay of patients admitted in 1951, excluding 4 1% total who remained longer than twelve months

ABLE VI—LENGTH OF STAY BEFORE DISCHARGE OR DEATH

—	Average stay (days)					
	All ages			Aged 60 and over		
	Males	Females	Total	Males	Females	Total
fore discharge	6[illegible]	54	53	56	57	56
„ death	33	46	39	32	46	39
ll patients	44	51	47	45	52	48

98 in 1952, and to 201 in 1953 Women patients caused lmost the whole of the increase

It is true that most elderly patients occupy beds little onger than younger patients (Graham 1951 Amulree t al. 1952) Almost half (49%) of the patients leaving he unit in 1951 stayed less than one month and 85% ad an average stay of less than one month Yet even small proportion of long-stay patients in the intake f successive years can cause serious cumulative obstruction of beds. Although only 3 8% of all patients admitted n 1950–52 stayed longer than twelve months more than 8% of the unit's 707 beds were occupied throughout 1953 by long term patients admitted before Jan 1, 1953 f the 201 patients who occupied beds throughout 1953, 141 were women (who occupied 35% of 399 beds in emale wards) and only 60 were men (who occupied 19% the unit's 308 male beds) Table VIII shows that 145 oth sexes) had been admitted in the years 1950–52 d 56 in earlier years before the survey began 14 had mpleted ten years stay by the end of 1953 of whom were under sixty years of age at the time of admission a reminder that younger victims of chronic disease o need hospital beds for long periods

ABLE VII—AVERAGE LENGTH OF STAY BY A SMALL MINORITY OF LONG-TERM PATIENTS BASED ON PATIENTS LEAVING GERIATRIC WARDS IN 1951

Classification by age and length of stay		Number of patients	% of total	Total patient days	Average stay (days)
All ages	Under one year	3105	96·2	145 640	46·9
	Over one year	121	3·8	117 326	969·6
	Total	3226	100·0	262 966	81·5
Aged 60 and over	Under one year	2474	95·8	118 120	47·8
	Over one year	110	4·2	99 476	904·3
	Total	2584	100·0	217 596	84·2

About a third of all long term patients leaving the nit between Jan 1, 1951 and Dec 31, 1953 were ischarged or transferred:

	Discharged	*Died*	*Total*
1951	41	80	121
1952	37	73	110
1953	31	68	99
Total 1951–53	100	[illegible]21	320

hese proportions of discharges and deaths give a somehat gloomy but far from hopeless picture of prognosis long term patients

The unequal sex-distribution of the long term patients able VIII) explains most of the apparent difference in the turnover of male and female beds in this series (table IX)

ABLE VIII—LONG-TERM PATIENTS REMAINING ON DEC 31 1953

Year of admission	Males	Females	Total
1952	22	49	71
1951	13	38	51
1950	6	17	23
1949	6	7	13
1948	3	8	11
1947	3	9	12
1946	—	4	4
1945	—	1	1
1944	—	1	1
Before 1944	5	9	14
Total	60	141	201

Demand for Beds

The demand for the unit's beds can be assessed from waiting lists, which have been counted weekly since the beginning of 1951 (table X)

The long waiting lists created by the influenza epidemic in the first quarter of 1951 were virtually cleared by the autumn of that year Thereafter the total numbers waiting in any one season show a steady increase. Once again however, this increase is not evenly distributed between the sexes Men show a slight increase but their rising trend appears to have been checked in the first part of 1954 Women show a greater and more consistent increase from October, 1951 to June 1954 In 1951 male and female waiting lists were about equal, but in 1953 the female list was almost twice as large as the male list

TABLE IX—ADMISSIONS PER BED IN 1953

—	Males	Females	Total
Number of admissions	1418	1504	2922
Number of beds	308	399	707
Admissions per bed	4·60	3·77	4·13
Beds blocked throughout the year	60	141	201
Beds available for admissions	248	258	506
Admissions per available bed	5·71	5·83	5·77

The major deficiency at present is clearly in female beds 90 have been made available in a newly opened hospital, administered by the same management committee and it is planned to increase this accommodation to over 250 beds within the next twelve months.

Discussion

Many social changes contribute to the growing demand for institutional care of the elderly but the basic cause is the changing age distribution of the population The Royal Commission on Population (1949) taking the year 1947 as a datum line and assuming a falling mortality, estimated that people over sixty five years of age would show an increase of 20% by 1963 and of 64% by 1977 The latest statistics show that in 1947–52 these age groups did in fact increase by 7 7%—an annual rate of 1 5%—which is in close agreement with the estimate Of even greater importance to the hospital services is the redistribution within the age structure of these older age groups Between 1947 and 1952 the number of people aged seventy five and over increased by 14%—almost double the rate of those aged sixty five and over (Annual Abstract of Statistics 1952 and 1953)

TABLE X—AVERAGE WAITING LISTS JANUARY 1951 TO JUNE, 1954 BASED ON WEEKLY COUNTS

Period of year	Males				Females				Total			
	1951	1952	1953	1954	1951	1952	1953	1954	1951	1952	1953	1954
1st quarter	181	66	61	32	133	44	79	111	317	110	140	162
2nd „	21	18	34	34	47	34	65	91	69	49	98	125
3rd „	6	1	[illegible]1		23	8	29		29	9	53	
4th „	3	10	16		9	[illegible]6	66		12	44	81	
Whole year	53	26	33		54	27	60		106	53	93	

In the general population as in the present series, increasing age is more obvious among women than among men In these five years women aged sixty five and over increased by 10% men of the same age by only 4% The sex-difference in the age groups over seventy five is less conspicuous but women show a greater rate of increase than males. Although our local population (Merseyside Conurbation) has a lower percentage of elderly people than the national population there are 173 women to every 100 men of over seventy-five on Merseyside, compared with 162 women to every 100 men in England and Wales (Registrar-General 1952)

The high rate of increase in the age-groups over seventy-five affects the hospital services in two ways First, because among the over-seventies there is a sharp increase in frailty, dependence on others, and demand for institutional care (Sheldon 1950, 1954) For example, the 1951 census returns (1% sample) showed that 48% of men remained in whole-time employment after the age of sixty-five, but only 20% after the age of seventy Similarly, the Wolverhampton survey (Sheldon 1948) showed that the proportion of women undertaking the sole domestic care of their household remained fairly constant at about 50% between the ages of sixty and seventy-four, but declined to 40% after seventy five and to 18% after eighty years As long as morbidity continues at present levels, any increase in these older age groups must cause a disproportionate rise in the demand for hospital beds Lowe and McKeown (1950) calculated age specific rates for patients in hospitals for the chronic sick per 1000 of the Birmingham population their rates show a remarkably sharp increase in the older groups

Age	*Rate per 1000*
55–64	1 53
65–74	6 38
75–84	22 21
85 +	58 93

This survey also suggests that an increase in the age of patients admitted to geriatric beds will tend to reduce turnover—both by increasing the proportion of long stay patients and by lengthening the average stay of those discharged

The Wolverhampton survey drew attention to the fact that the lower mortality of old women is accompanied by a morbidity higher than that of old men, and there has since been ample evidence that the proportion of hospital accommodation required for older women is far greater than can be explained by their greater numbers Greenwood (1949), Exton-Smith (1952), Morton (1952), and Andrews and Wilson (1953) all quote examples of the disproportionate demand for female beds, and in the Birmingham survey women had a higher age specific rate than men at all ages after seventy-five

Estimates of future hospital scales based on the total numbers of both sexes, either in the whole population or in the combined age-groups over sixty or sixty-five years, can have only a short-term reliability Long term planning should take account of the changing age-structure and sex distribution of the older population

The difficulties of long term planning have been discussed in a P E P study (1954), which reviews basic assumptions about trends in birth rates and mortality, and suggests that previous estimates of the economic burden of old age may have been exaggerated Fortunately changes in the birth-rate cannot directly increase the burden on the geriatrician for sixty years or more —though the size of the working population will influence the amount of the national income available for welfare services, including hospitals The future demand on the hospital services will depend both on the numbers of old people alive, and on the incidence of disease among them It is a melancholy thought that many of the problems of old age are a by-product of unbalanced medical progress We can prevent or cure many of the diseases which used to kill we cannot yet control many of the more insidious diseases which disable those who survive into an extended old age The control of arterial degeneration would probably do more than any other scientific advance to reduce the social and economic problems as well as the suffering of old age Extra longevity without lower morbidity is a doubtful blessing for most of us Old age must be made healthier and more useful if it is to be anything but an increasing burden, both to the individual and to the community

It is a pleasure to acknowledge the willing assistance of many members of the hospital staff I am especially indebted to Miss C Ledsham and others who helped in the tedious work of extracting the basic figures for this survey

SALARIES IN THE PUBLIC-HEALTH SERVICE

Under an Industrial Court award which operates as from Jan 1, 1955, medical officers of health, senior medical officers, and medical officers in departments (assistant medical officers) are to receive increases in salary ranging from £175 to £200 The new salary scales are as follows

Medical officers of health

Population Group	*Commencing salary*	*Increments*
Not exceeding		
75,000	£1625–£1830	4 × £5[illegible] 10s
100,000	£1730–£2040	6 × £51 10s
150 000	£1940–£2250	6 × £51 10s
250 000	£2150–£2450	2 × £100 1 × £50
400,000	£2400–£2700	2 × £100 1 × £50
600,000	£2500–£2900	3 × £100
Over 600 000	At discretion	At discretion

Senior medical officers

£1415 × 50–£1765 × 65–£1830

Medical officers in departments (assistant medical officers)

£975 × 50–£1375

The court found against a proposal to introduce in Scotland a salary scale for a medical officer of health with a population group not exceeding 60,000

WHOLE-TIME AND PART-TIME CONSULTANTS

The Joint Consultants Committees have had recent discussions with the Ministry of Health and the Department of Health for Scotland about whole time and maximum part time service for consultants in the National Health Service, and the following is an agreed statement of the position

It is recognised that some consultants, while prepared to devote substantially the whole of their time to hospital work and to give it priority on all occasions, would prefer a maximum part-time to a whole time contract Ever since 1948 it has been the Ministry's view that, subject always to the needs of the hospital service, employing boards should in this matter take into account the circumstances and preferences of the consultants concerned While there has been no previous statement on this point as regards Scotland, the practice in that country has been similar

Where a new appointment is being made this means that, except where the board decides that the needs of the hospital service (considered in conjunction with the of the local health services where the consultant is to undertake duties on behalf of a local authority) demand a whole time appointment, the competition should be thrown open to all applicants who are prepared to give substantially the whole of their time to the post, whether they prefer a whole-time or a maximum part time contract In such a case the successful candidate should e asked to state his preference until after he has been elected for appointment

Similarly, if a consultant who is already employed in whole time post wishes to transfer to a maximum part-ime contract, or vice versa the board should, before eaching a decision, take his circumstances and preferences into account again subject to the overriding needs of he hospital service.

This statement does not, of course deal with the many ases where the services of a consultant are needed in the ggregate for only a limited volume of work and where erefore a part time appointment would in all cases be ppropriate.

Public Health

Vaccination in London

At a meeting of the London County Council on April 20 t was stated that the percentage (based on live births) of London children under 1 year vaccinated against smallpox hows a steady improvement since 1949 The figures re as follows:

1949	25%	1951	38%	1953	48%
1950	32%	1952	45%	1954	49%

There is continual propaganda on the part of the ouncil's health visitors and clinic doctors to persuade others to have their young children vaccinated General ractitioners are encouraged to take their part in vaccina on and are paid a fee of 5s for each notification sent to e council. Opportunity is also taken to encourage accination by the distribution of literature and display f appropriate material in council establishments

Notification of Tuberculosis

A recent Ministry of Health memorandum[1] explains which medical officer of health should be notified when a erson is diagnosed in hospital as suffering from tubercu sis. Notifications should usually be sent to the medical fficer of health of the district in which the patient ormally lives; but where in the case of long-stay atients, the hospital itself can reasonably be regarded s the *patient's place of residence the notification should* e sent to the medical officer of health of the district in hich the hospital is situated.

Swedish Poliomyelitis Vaccine

As we reported a fortnight ago[2] plans are going ahead Sweden for the use of a poliomyelitis vaccine made growing virus on human tissue Further details have en given in a report by Prof Gunnar Olin of the edish State Bacteriological Laboratory The virus as been grown on aborted human fœtal tissue, and then activated with formalin (1 in 2000 compared with the in 4000 formalin recommended by Salk) The inacti ation is performed at 25 C (the American workers efer 37°C) The antibody response is said to be good hough vaccine has been prepared to immunise 120 000 hildren, but further supplies may be limited by the hortage of suitable tissue for culture American vaccine ay be imported for the time being

Education of Physically Handicapped

The Ministry of Education[3] has found that on Oct 1 31 1052 children were awaiting places in special schools. heir disabilities were as follows: cerebral palsy 485 liomyelitis 100 heart defects, 78 muscular dys-ophy 78; spina bifida, 68 hydrocephalus, 42 formities, 40; hæmophilia 20 fragilitas ossium, 20 berculosis 10; Perthes's disease 12 muscular atrophy, rheumatoid arthritis, 3; others, 83

Of the 1052 children 202 were awaiting places in day hools and 850 in boarding schools. The existing ucational arrangements for these children were as llows: 371 were receiving home tuition 250 were ordinary schools; and 100 were receiving some other pe of special educational treatment (mainly in hos itals). Of the 725 unprovided for some were not receiving home tuition because of difficulty in finding teachers or of unsuitable home conditions

There appeared to be enough places in day special schools There is still a shortage of places in boarding schools but additional places expected to come into use within the next two or three years should suffice for all children whose parents are likely to consent to their attending such schools

First Quarter in England and Wales

The Registrar General, in his provisional figures[1] for England and Wales in the first quarter of 1955, records a birth rate of 15·5 per 1000 population, compared with 15·9 per 1000 in the first quarter of 1954 The death rate was 15·4 per 1000 population, as against 14·0 per 1000 in the first quarter of 1954 The infant-mortality rate was a new low record for a March quarter—29·0 per 1000 related live births It was 31·0 per 1000 (the previous record) in the first quarter of 1954 The stillbirth rate was 23·1 per 1000 live and still births compared with 23·7 in the *corresponding quarter of* 1954

Parliament

Disseminated Sclerosis and War Pensions

In the House of Commons on April 20 Mr ARTHUR MOYLE asked the Minister of Pensions and National Insurance to examine the rules and the present terms of the Royal Warrant to see whether ex-Servicemen with disseminated sclerosis might not be assessed at the 100% disability rate—Brigadier J G SMYTH joint parliamentary secretary to the Ministry pointed out that in the first world war two-thirds of the casualties were wounds In the second world war the causes of two thirds of the pensionable cases were diseases. But to earn a war pension these diseases must be causally connected with service *There was no evidence that* disseminated sclerosis was in any way a military disease. The Ministry tried, however, to stretch the regulations as far as they could and where a man had been subjected to a sudden shock, and within a short period showed signs of disseminated sclerosis they said that perhaps the shock, although they knew it had nothing to do with the disease had accelerated its progress and pensions were granted for aggravation Accordingly after the late war pensions for aggravation of disseminated sclerosis were awarded in 1538 cases and there had been 1117 rejections.

QUESTION TIME

Ban on Heroin Imports

In the House of Lords, replying to a question Lord MANCROFT said that except for small quantities for purely scientific purposes Her Majesty's Government had decided not to permit the manufacture and export of heroin after Dec 31, 1955 As adequate supplies had hitherto been manufactured in this country imports of heroin had not been authorised for many years: it was intended to maintain the prohibition on importation. The Government had taken this decision in order to give effect to a resolution adopted by the Economic and Social Council of the United Nations at its 18th session, urging all governments to prohibit the manufacture export, and import of this drug except for scientific purposes. Before the *decision* was reached the advice of the appropriate statutory advisory bodies was taken.

Viscount ELIBANK Are the Government aware that Dr Arthur Douthwaite senior physician at Guy's Hospital, has stated in the *British Medical Journal* that the banning of this pain killing drug heroin, is an astonishing move which will inflict much hardship upon a multitude of patients? Is the noble Lord aware that one of the best known physicians in Edinburgh, Dr A B Flett has written to me saying it is iniquitous that this most useful, and often, in certain cases really necessary drug should be banned?—Lord MANCROFT: The Government are aware of these opinions On the other hand I understand that adequate supplies of perfectly good substitutes for this drug are now available The purpose of the action is, of course to facilitate the world wide banning of traffic in this extremely dangerous drug

---

[2] *Lancet* April 23 1955 p 857

[3] Ministry of Education: administrative memorandum no. 503 April 25 1955

[1] Registrar-General weekly return no 15 1955 H.M. Stationery Office 1 p. 20 1s

I do not think that the Government can do more than follow the technical advice and guidance given by the Central Health Services Council, the Standing Medical Advisory Committee, and the appropriate bodies in Scotland and Northern Ireland

Poliomyelitis Vaccine

Replying to questions, Mr Iain Macleod, the Minister of Health, said that a small field trial with the Salk poliomyelitis vaccine was being carried out by the Medical Research Council All vaccine used in this trial, whether imported or manufactured here, would first have been the subject of rigorous tests by the council Plans for large scale immunisation were, of course, dependent on the Minister of Health being satisfied, so far as was humanly possible, as a result of these tests and trials that the vaccine to be used was both efficient and free from danger

Mr Eric Fletcher Would the Minister say whether any supplies of Salk vaccine from the Cutter Laboratories have been received in this country ?—Mr Macleod No Cutter vaccine has been received in this country

Mr Mont Follick Are the vaccines which are being made by the Glaxo Laboratories of their own special prescription, or according to a prescription imported from America ?—Mr Macleod I understand that what they are making is, in fact, the Salk vaccine The difficulties in this case have arisen, I understand, from a batch made by the Cutter Laboratories As we have none from those batches in this country, there should not be difficulty in that particular direction

Salaries of Hospital Pharmacists

Replying to questions Mr Macleod said that a general agreement on increased salaries for hospital pharmacists was reached by the appropriate Whitley Council on April 20 Details were now being worked out

General Practitioners in the N H S

Replying to questions, Miss Patricia Hornsby Smith, parliamentary secretary to the Ministry of Health, said that on July 1, 1954, 19,300 general practitioners were practising in the National Health Service Altogether 837 doctors practised single handed and 614 partnerships employed assistants, other than trainees The Minister of Health was not prepared to limit the increased number on a list when an assistant was employed to a maximum of 1500 The relationship of principals and their assistants could not readily be regulated by statute

Mr Somerville Hastings Does not the Minister realise that many doctors find great difficulty in getting the necessary capital to start in practice and are therefore liable to be exploited by doctors who employ them as assistants ?—Miss Hornsby Smith The matter is being considered by the British Medical Association and the Medical Practitioners' Union, but we have had no decisions or opinions from them yet

Mr H Marquand Does the hon lady recollect that it was a definite promise by the medical profession at the time when the payment to general practitioners was referred to adjudication that they would seek to reduce the number of assistants and increase the number of principals in practice ? Is she satisfied that the medical profession are giving real coöperation in this matter as they undertook to do ?—Miss Hornsby Smith There has been an increase in partnerships and a reduction in the number who do a long period as assistants These consultations are going on between the B.M.A and the M P U and I think the profession are coöperating in this matter where they feel that there is hardship Mr Hastings said that the B M.A. committee had already reported and their report was by no means entirely happy about the situation

Replying to a further question, Miss Hornsby Smith said that on July 1, 1954, 131 assistants were still in posts which they had taken up before July 1, 1949 Mr Hastings Does not the Minister think that this is a serious matter ? Even her own figures show that While it is admitted that doctors may derive a good deal of benefit from being assistants for a time, does she not agree that for them to go on year after year in that position, as these figures suggest, is a very dangerous situation ?—Miss Hornsby Smith I think we should keep this matter in proportion There is a steady increase in the trend towards partnerships Mr Marquand Would it not be possible to make an inquiry into this comparatively small number of cases to see what the reason is for this long period of assistantship ?—Miss Hornsby Smith We will consider that point

Lung-cancer Mortality

Replying to a question, Mr Macleod said that the provisional number of deaths attributed to cancer of the [illegible] 1954 was 16,332 The numbers of deaths so attributed in [illegible] and 1944 were 2775 and 6684

Mr Hastings Does the Minister realise the importance to the health of the community resulting from his pronouncements on this subject some few years ago ? Will he consider making a similar pronouncement setting forth the increased knowledge up-to date resulting from research ?—Mr Macleod I recognise the public anxiety here and I shall be very glad to consider the suggestion Dr Barnett Stross Would it not be true to say that whatever may be the cause of this disease—and many people now suspect what may be the cause—it cannot be the ingestion of any foodstuffs that is causing the rise in cancer of the lung, for it would affect women as well as men, and that it does not do ?—Mr Macleod Whatever may be the reason, it is true that the increase is very much more—indeed it is more than twice as great—amongst men than women, which would seem to indicate a special cause

Child's Treatment in Hospital

Mr Kenneth Robinson asked the Minister why a boy aged 10, who was admitted to Hampstead General Hospital on March 30 with a fractured and dislocated arm, received no medical attention for more than six hours, during which time he was offered neither food nor a sedative —Mr Macleod replied I am very much afraid that the facts are as stated and it is clear that the hospital staff failed grossly in providing proper attention On behalf of the board of governors and myself I must apologise to the child's parents I assure them that the board take a serious view of the whole incident and that those responsible have been severely reprimanded Mr Robinson Whilst I welcome the Minister's admission of the responsibility of the board of governors for the matter, and, of course, accept his assurance of regret, does he not agree that the public has been led to expect that the teaching hospitals should set a standard of conduct in these matters, and does that not make the incident even more deplorable ?—Mr Macleod No doubt that is true I am bound to say that the only thing I welcome about this case is that the hospital at once admitted an error As we know errors happen in the hospital service I deeply regret that this should have happened, and my views have been put very strongly to those concerned Mr Hastings Will the Minister make it quite clear that it is his desire that at every general hospital there should be a medical cover throughout the twenty four hours, and that so many doctors should not be away from their work as at present ?—Mr Macleod It is certainly desirable that wherever possible cover should be provided, if not on a twenty four hour basis, at least urgent and near

Requests for Lists of Patients

Replying to a question, Miss Hornsby Smith said that the Minister of Health was not aware that political party organisations were asking doctors for lists of patients for the purpose of the postal vote at the general election

Mrs Barbara Castle I have in my possession circular letters from Conservative associations to local doctors in their areas asking them to supply the Conservative party with the names of blind, sick, and aged patients on their registers in order that they may be contacted with a view to their having a postal vote Will the Minister institute an immediate inquiry and inform the doctors that this is contrary to professional etiquette and their duty to their patients ?—Miss Hornsby Smith If the hon lady will let the Minister have the evidence I can assure her that he will look into the matter The vote is secret and in their individual capacity it is certainly helpful to see that as many as possible obtain their vote

Mr Herbert Morrison Will the hon lady on behalf of the Minister give an assurance that neither directly or indirectly will those associated with the National Health Service be coöperators with any political party organisation in connection with the forthcoming election ? Is she aware that there was the strongest impression at the last election that such malpractices took place ?—Miss Hornsby-Smith I can certainly give the assurance that the Health Service will not be used in this way

Replying to further questions, Mr Macleod said he would ook into this matter at once Whether he would make a tatement on it would depend on the results of his inquiries.

Orthodontic Treatment

Replying to questions Miss Hornsby-Smith said that he number of courses of orthodontic treatment approved nder the National Health Service for 1949 was 12 000 and he payments made were £300 000 The figures for 1954 ere 48 000 and £500 000 Orthodontic treatment was rovided under the hospital and specialist services, the school ealth service and the general dental services. The number f dentists in England and Wales who in 1954 were each given pproval to start more than 100 courses of orthodontics under he general dental services was 42

Medical Examination of Broadmoor Prisoners

Mr T E Driberg asked the Home Secretary if he was ware that a medical report by the principal medical officer f Brixton Prison dated Feb 14 1953 stated that a prisoner was sane and fit to stand trial on a charge of attempting to murder his wife and recommended him as suitable for voluntary treatment in a mental hospital; that at his trial five days later this man was found guilty but insane and ordered o be detained during Her Majesty's pleasure and that he is till detained at Broadmoor where his wife and other relatives had found him in apparently normal health and if in these circumstances, he would allow an independent medical xamination of this patient.—Major Lloyd George replied The responsibility for deciding when a Broadmoor patient s fit to be transferred or discharged rests on the Home Secretary and my predecessors and I have consistently taken the view that the expert staff of psychiatrists at Broadmoor who have the patient under constant observation are n a better position than an outside doctor to advise the Home Secretary on the patient's mental state and future prospects. The answer to the last part of the question is, therefore No Sir

Mr Driberg Is the Home Secretary aware that Dr Mathieson, of Brixton, also said that this man was suffering imply from a mild anxiety neurosis, which should yield to proper psychiatric treatment but that since he has been in Broadmoor he has had no such treatment whatever? It is obviously impossible for the very efficient and conscientious staff at Broadmoor to give proper psychiatric treatment to the very large number of patients with whom they have to deal. In the circumstances, will the Home Secretary consider either getting an independent opinion r transferring the man to a mental hospital where he can be treated?—Major Lloyd George: These cases are very difficult I am aware of the opinion to which the hon Member has referred and I have of course gone into the case myself with great care On the information I have I do not think anything can be done But I am prepared to look at the matter again and I will do so

Motoring Offences and Blood Tests

Replying to a question, Sir Hugh Lucas Tooth, joint under secretary of State to the Home Office said that during the last ear no motorist charged by the Metropolitan Police with being under the influence of drink while in charge of a car had requested a blood test but in one case samples of blood and urine were taken at the request of a doctor called on behalf of a person who had been arrested for such an offence

Mr Somerville Hastings: Does the Minister not agree that this test which has been largely used in other countries might usefully be tried out in this country so that some idea would be obtained of its real value? At present its value seems to be somewhat uncertain. Will the test be made possible for those who apply for it?

Sir Hugh Lucas Tooth: Opinion about the value of blood tests in these cases is sharply divided, and it would be inappropriate for me to express a view either way at the present time. Research on the effects of alcohol upon driving performance is being carried out by the Medical Research Council and the Road Research Laboratory

Mr R. R. Stokes: Have not the police chucked this bit of nonsense as being absolutely unreliable?

Replying to a further question Sir Hugh Lucas Tooth said that the provisional figures showed that in magistrates courts in England and Wales there were during the first nine months of 1954 1051 convictions of driving or being in charge of a motor vehicle while under the influence of drink or drug The number of resulting sentences of imprisonment was 112

In England Now

A Running Commentary by Peripatetic Correspondents

They say a psychiatrist is a man who goes to the Folies Bergère to look at the audience, so I went to the Private View day at the Royal Academy The trouble about Private View day is that you get trampled underfoot by people with one eye on the pictures and the other on the look-out for their friends But still, it has the advantage that the ladies hats are more surprising than they are on other days, and the girls seem prettier and you can watch the artists being casual about their masterpieces They have a variety of techniques for this. I heard one ask, in incredulous tones, 'Do you mean you *like* it? but whether this was modesty, or surprise that his audience appreciated it, I could not tell. Then I like to see the subjects standing sheepishly near portraits of themselves. I am one of those people who do not get much further in Art than knowing what they like, but I did like the portraits this year there were several startlingly good ones and very few of those others. I liked the one of the toy monkey because he unlike most of the other sitters, was not pretending to be blase about having his picture painted There were, of course, the usual dreary people sitting in dreary rooms but I wonder how Charles Spencelayh manages to make ordinary objects so exciting? I suspect that the secret lies in the title he has given to one of his groups—*God's Good Things* Perhaps it is because I like bouncy dogs, but I was intrigued by *Whippet* in terra cotta, who had curly ears and a curly tail and was very much alive. 'And ducks are soothy things and lovely on the lake That was another lovely thing in oak, a mother duck obviously telling her brood a bedtime story Exciting in a different way is a statue of a nun, with severe straight lines except for her face and expressive hands. There is so much too much, to take in as always The biggest crowd was consistently round what has now come to be known as the Annigoni of the Queen For the record the most frequent remark I heard in the whole exhibition was The traffic my dear, was simply frightful.

* * *

My medical wife and I discussed the mushrooms fully Growing they were pleasant-looking things and after consulting the encyclopædia we convinced ourselves that they were edible We ate them for breakfast the following day and I had a large helping which tasted delicious with bacon My wife drove me to the hospital where I sat down in the office to attend to some routine papers Some thirty minutes after breakfast the odd feeling started I found it difficult to concentrate on my work and noticed a transient diplopia which could be mastered only by an effort. I experienced a curious sensation of being in the room but apart from my body The voice of someone speaking in an adjoining office seemed a great distance away Of course this disturbed me but the probable cause eluded me for a while. Then—The Mushrooms! I grabbed the phone and with some difficulty dialled my home. With great relief I heard my wife s voice, though it was slurred and not too intelligible. In the brief moments of waiting for her to answer I had an awful vision of her having crashed the car on the way home She too felt very odd and had just realised why By this time I was getting a bit disorientated but I sent one of my colleagues off to bring my wife my daughter, and the lodger into hospital. I then floated rather than walked up to the ward for a stomach pump session. I was given atropine and intravenous glucose and rapidly felt better

My wife who was not treated so soon became quite confused and went into a state of shock before she reached hospital but fortunately retained enough presence of mind to insist on picking up the lodger from her office on the way The three of them were then treated as I was, to the intense indignation of daughter aged eight who had eaten only one small mushroom and felt quite well They too improved rapidly, but my wife remained mildly shocked for several hours

I found it impossible to get the fungus identified but assumed that it was one of the types containing a mus carine-like alkaloid—possibly *Inocybe patouillardi* I don't think it could have been *Amanita muscaria*, which from its pictures seems a distinctive fungus quite unlike our specimens

The story spread rapidly and, needless to say, such an occurrence in a medical family was the cause of much ribald comment The loudest laugh was enjoyed by my son aged twelve who doesn't like mushrooms and who refused them on this occasion because he didn't like the look of them His big moment came when he poked his head into my hospital room and said "I told you so!"

* * *

Some of our West End colleagues still bemoan the loss due to war, the B B C, and Big Business, of the Langham, and now the Bolivar—its posteriorly situated vestigial remnant—has suddenly closed its hospitable doors It is heart-rending to see thirsty pillars of our profession being caught out by padlocked doors without so much as a "closed" notice on them I saw one famous man nip round the corner to check his watch against the All Souls' clock before the devastating truth dawned upon him Where consultants' fluid-balance and milli-equivalents can conveniently be put in order now, goodness only knows What with this calamity and the Med Soc Lond having no visible means of support at its northern end, Chandos Street is not what it was

* * *

Those who heard Pierre Monteux conducting the Royal Philharmonic Orchestra at the age of 80 must have marvelled at his apparently limitless energy Bruno Walter, one year younger, is to take command of the B.B C Orchestra this month It is only a few years since Toscanini, now 88, electrified us all at the Festival Hall Vaughan Williams, at 83, would probably call himself an amateur conductor only Weingartner, Mengelberg, Richard Strauss, and Kussevitzky were all around, or well above, 80 when they died in full harness Sir Thomas, of course, is a mere stripling at 75, he, Cameron, and Ansermet are a trio of active septuagenarians Sir Henry Wood had hardly shed any of his habitual load of work when he died at 75

It is fortunate for the rest of us that these eminent maestros enjoy such long spans But why do they? Is it because, unlike most surgeons and professors, they keep on working? Or are eminence and longevity associated irrespective of occupation? Quite apart from ex-prime ministers, Augustus John and Brangwyn are well into their eighties, Sir Gerald Kelly and Sir Alfred Munnings are in their late seventies

A famous but still relatively young conductor once told me that, while in action, he felt "the vital juices flowing down the arms to the heart" Perhaps he was right, perhaps the apparent immunity of orchestral conductors to the more spectacular forms of cardiovascular collapse is due to the fact that they wave their arms about a good deal

* * *

How much we suffer from failure to convey our wishes correctly to our patients Listening to one's colleagues shows how much time and effort are wasted by lack of liaison

"Lie on your back on the couch—No, on your back, please"

"Show me where the pain comes—No, on your own back please"

"Please stand up—now, raise your right leg—thank you, and now your left leg—thank you, and now get off the floor"

There is clearly an urgent need to revise the technique of medical questioning, and at the next twelve unselected outpatient clinics we are giving a trial to the following phrases

"Lie on the couch with your tummy upwards"
"Show me on your own back where the pain is"
"Bend your knee crooked—and now bend it straight"

I would welcome suggestions how to avoid the inevitable contraction of the calf muscle just as I withdraw the tendon hammer from my pocket "Relax," "Pretend you're asleep," "Don't bother about me," "Go loose," and "Pretend you're dead" have been tried and found wanting

Letters to the Editor

HASHIMOTO'S STRUMA LYMPHOMATOSA

SIR,—Independently, we have each been interested several years in Hashimoto's "struma lyphomatosa" 1953, again independently, we obtained marke abnormal liver-function tests in some of these cas finding of which we have seen no previous record, and which one of us drew attention in your columns year[1] This mutual interest came to light when we by chance on the slopes of a Yorkshire mountain, not having met as colleagues for over twenty years. intend to record our findings in full in due course but preliminary details may interest your readers

Owing to a difference of approach there is some of uniformity in our case records, but we are agreed the main observations

(1) The presumptive diagnosis is essentially clinical the condition is commoner than is generally suppos Although there are certain typical features, includ preponderance of cases in middle aged females, sympto of subthyroidism of variable degree, and a thyroid easily felt and abnormally firm, we would stress that infrequently the patient first visits her doctor for sym toms not quickly ascribed to thyroid disturbance, as lassitude, muscle and joint pains, increasing weig and changed facial appearance The efficacy of mod treatment by oral dried thyroid emphasises the need the diagnosis of Hashimoto's disease to be consider more readily We have studied about 25 patients, nearly two thirds of whom the diagnosis has confirmed by surgical section

(2) The basal metabolic rate is subnormal in most the patients when first seen, but a minority in the stage show signs and symptoms of hyperthyroidi Anæmia is not a characteristic feature

(3) The liver function test most consistently abnor in the untreated patient is the colloidal gold te thymol turbidity and flocculation tests generally parallel with it In a few patients the serum alka phosphatase is slightly or moderately raised T bromsulphalein test may be abnormal, but the galac tolerance has been normal in the 5 patients exami After treatment by dried thyroid gland, the liver-func tests in some patients return to, or towards, nor within a period of months, but in others the retur much slower and we have seen the tests still gro abnormal after more than two years Electrophor shows a raised and abnormal serum-globulin level in few patients In general, however, there appears to no close relationship between the results of the flocc tion test and the plasma cholesterol, or the ba metabolic rate

(4) We suspect that gross liver disease may arise struma lymphomatosa One of our patients, observed seven years, now has a liver which is greatly enlarg and abnormally firm, and a palpable spleen The spl is palpable in 2 of 17 other patients In the 1 patient whom surgical biopsy of the liver has been possi however, the histology was normal

(5) We have not yet seen such gross changes in th liver-function tests in typical primary myxœdem although lesser degrees of change have been observed.

(6) We are impressed by the steady diminution the size of the thyroid gland during treatment by dr thyroid, this point is not mentioned in the literatu but it was emphasised by Crile in his Moynihan lec to the Royal College of Surgeons in January, 1954

STAPHYLOCOCCAL INFECTION IN THE NEWBORN

ir,—We fear that others, like ourselves may interpret paper by Dr Forfar and his colleagues (March 19) simply as a clinical and bacteriological study but as a ommendation that all infections in newborn babies in ternity hospitals should be treated with erythromycin feel that such a recommendation would be misguided d we should like to comment upon it The clinicians ongst us made the mistake of adopting just such a icy some years ago and we have lived to see its fortunate long term consequences We have also rnt more about the nature and dangers of staphylo cal infection in the newborn as a result both of close laboration between clinicians and bacteriologists and more critical clinical observations in our hospital during past few years We accordingly reversed our previous licy some time ago, and have as yet had no cause to ret this decision The fact that the antibiotic with ich we were concerned was penicillin not erythromycin does not appear to be relevant since as Forfar d his colleagues admit, there is evidence that sooner later staphylococci become resistant to erythromycin

For us the crucial fact is that the more frequently the phylococci in a particular community are exposed to a ticular antibiotic, the more likely are they to become istant to that antibiotic. If there were any overriding vantages to be gained by using an antibiotic as freely Forfar and his colleagues recommend the inevitable dvantage would have to be accepted But although y state that "Edmunds et al (1955) show that early ognition and early treatment of minor staphylococcal ection in the newborn play an important part in venting serious sepsis" we can find no evidence atever to support this statement in the paper to which y refer[1]

We have not treated any case of skin sepsis when t seen during the past twenty months unless it was extensive pustular rash in a small premature baby, we had other grounds for believing that the baby ill

uring this period 163 cases of skin sepsis have occurred tules and paronychia): 11 were treated from the start use of one of the indications we have mentioned 11 e treated later because the local lesions were extending r a period of forty-eight hours observation and the aining 141 cases (86%) received no treatment of any kind n they remained well and the local lesions were clearing or cleared after forty-eight hours.

uring the same period of twenty months virtually all s of sticky eye developing after the first twenty four rs of life were treated simply by local instillation of 10% hacetamide The cases which developed within the first nty four hours were left untreated unless they failed to lve spontaneously during a period of forty-eight hours ervation because we know as a result of earlier work in this spital[2] that a *Staphylococcus aureus* can be cultured from than 10% of these early cases. Altogether 470 cases of ky eye were recorded during the twenty months.

We should like to mention that no serious infection of y kind (pneumonia, osteitis &c) developed in any of 633 babies suffering from a superficial infection and ated on the conservative lines we have indicated

We did encounter a serious infection during this riod in a baby who died of a staphylococcal pneumonia the thirteenth day of life but there was no clinical perficial infection in this baby at any stage We also d to use a systemic antibiotic on a number of occasions ause a baby appeared to be ill and probably infected the absence of any minor superficial infection whatever We feel that this experience supports our present licy of restricting the use of all antibiotics to an absolute minimum since it has shown that this is not only desirable in theory but also safe in practice The real indication for antibiotic therapy seems to us to be a clinical diagnosis of systemic infection (with or without superficial sepsis) This indication is uncommon, but an effective antibiotic must be used at once in these circumstances and this is an urgent matter on which the baby's life may depend We feel that our chance of being able to use any particular antibiotic with confidence (before *the sensitivity of the organism from the particular case* is known) depends upon our past conduct in relation to that antibiotic. We are very glad to be in a position to keep erythromycin in reserve for the case that really needs it and whose life may very well depend upon it and we would like to think that others were exercising a similar restraint We cannot understand what has prompted Forfar and his colleagues to reverse the much more selective policy which they outlined in 1953[3]

ACID-FAST BACILLI IN ACHALASIA OF THE CARDIA

Sir,—Dr Davies and Dr Roberts (April 23) rightly emphasise the need for critical assessment of the finding of acid fast bacilli in the sputum in cases of achalasia of the cardia with respiratory symptoms A diagnosis of pulmonary tuberculosis may wrongly be made if such organisms are not cultured

Acid fast saprophytes are not uncommon findings in sputa in a number of other chronic pulmonary diseases and it is doubtful if they play any important rôle in them. In the lipoid aspiration pneumonia of achalasia of the cardia however, these organisms may act as pathogens and the bacteriological findings must not be summarily dismissed A fatal infection of this nature and a review of the subject has been published[4] Although mycobacterial strains freshly isolated from such cases generally show an unusual virulence for experimental animals especially mice it is the modification of the host's response brought about by the presence of fat in the pulmonary alveoli coating the organisms that appears chiefly responsible for the resulting illness. The cultural characters of the strains isolated vary from case to case and so these pulmonary infections differ from some of the recently reported non tuberculous mycobacterial skin infections such as that due to *Mycobacterium balnei*[5]

A BARBITURATE ANTAGONIST

Sir —I have read with interest the letter of Dr Morgan McElligott (April 16) in which he reports no change other than a deepening of respirations after the administration of 240 mg of ββ methyl-ethyl glutarimide ('Megimide') to a patient who had taken gr 72 of phenobarbitone Dr McElligott is not quite correct in thinking that the lack of clinical improvement was due only to insufficient dosage Certainly the dose for this case would have been 1 0 g and probably even then the patient would have regressed and required one or two treatments more But the important point is that treatment was not started until *six* days after admission

Megimide appears to be a specific antagonist to barbiturates. At the end of six days there would be little barbiturate in the body By this time however, there would have been extensive cellular damage—e g, cerebral œdema—and one would not expect any drug to reverse this injury

---

University of Melbourne, Australia F H SHAW

A VISIT TO KOLTUSHI

SIR,—Mr Ruscoe Clarke and Dr Leonard Crome (April 2) write that the objective of study at Koltushi "was an understanding of the functioning of the organism in its unity with the environment" They state that among the "general principles" used at Koltushi one was expressed in the statement "Descartes knew already that environmental factors determine the functioning of the organism by means of reflexes" In their conclusion, they state that they "had no more than a glimpse of the new science" They ask "was it a glimpse into the future?"

We are entitled to ask whether a science based on the study of the "conditioned reflex" is so new Is it a study likely to provide the kind of future we should all desire should come about? In his introduction to *The Use of the Self* by F Matthias Alexander, the late John Dewey wrote in 1932

> "The school of Pavloff has made current the idea of the conditioned reflex Mr Alexander's work extends and corrects the idea It proves that there are certain basic, central organic habits and attitudes which condition every act we perform, every use we make of ourselves This discovery corrects the ordinary conception of the conditioned reflex The latter as usually understood renders an individual a passive puppet to be played upon by external manipulations The discovery of a central control which conditions all other reactions brings the conditioning factor under conscious direction and enables the individual through his own coördinated activities to take possession of his own potentialities It converts the fact of conditioned reflexes from a principle of external enslavement into a means of vital freedom."

Mr Alexander enables a person to provide for his use a self acting as a unity with its environment by the following procedure

> The person inhibits his habitual reaction to a stimulus Thus he allows the head to go forward and up This sets in motion an innate reflex whereby the self as a whole instead of firstly directly reacting to its environment indirectly firstly acts as a whole outwards on the environment in all directions in the greatest possible degree Thereby the integrative action of the central nervous system is given freedom to work at its best Thereby the person is provided with a unified whole self he may use for reacting to his environment with kinæsthetic information about his guidance of his actions working in the best way

Bolton, Lancs MUNGO DOUGLAS

ARGININE DEFICIENCY AND MALIGNANT DISEASE

SIR,—I noticed an abstract of a paper by D L Horrigan[1] reporting the excretion of uracil in 3 out of 5 patients suffering from myeloid leukæmia It occurred to me that there might be a possible connection between this observation and the finding[2] that the growth inhibition of a micro organism by uracil was prevented by arginine It may be that uracil encourages malignant change by suppressing the growth of normal cells rendered arginine deficient by the invading neoplasm, which then grows at their expense The simplest test of this hypothesis would be the administration of arginine in cases of experimental or human cancer

As a microbiologist I am not equipped to make tests, but some of your readers may care to co the possibility

Banstead, Surrey E J MILL

REGISTRARS AND REGISTRARS

SIR,—I am a little surprised to read in your i April 23 so embittered and venomous an epistle as signed by Registrar (W plus) The writer's ignorance military ranks seems equalled by his lack of know of teaching hospitals If by any chance he is likely become a "failed registrar" he may perhaps be ab take shelter under the Strachan umbrella

London, S E 1 J J CONYBEA

SIR,—Registrar (W plus) has raised a subject of interest to all registrars One point which req further stress in the inequality of duties is the fact the same difference in the amount of work done registrars also exists in the teaching, but non profe units

There are many registrars (W plus) working in tea hospitals—not only in peripheral hospitals, as correspondent suggests The group he describes as trars (T) undoubtedly exists in professorial units. T add little or nothing to the every day (and night) ru of a hospital service, but they use the time and faci to acquire further qualifications, and write nume papers On these achievements they are often ele to consultant status in preference to registrars (W with a wealth of practical and useful clinical know and experience

Of course, many of these experimental studies are considerable value, but it is unfair, with the ever inc ing expense of the National Health Service, that expanding number of hospital staff should be seclude this type of work, whilst others of equivalent st provide a 24 hour hospital service Clearly the pr time for writing theses for higher degrees and pub ing articles is when one has sufficient knowledge experience to write with authority on the subject one's choice At the moment many higher degrees obtained by men working in a laboratory on a su chosen and supervised all through by their chiefs, finally examine them Unfortunately in the keen com tion for obtaining a consultant post, higher degre count, but in reality are these higher degrees of an clinical value? I doubt it!

REGISTRAR (W

PROTECTING THE MOTORIST

SIR,—There can be no doubt that in the near fu motorists will be more willing to use safety dev against motor car accidents Crowding on the ro plus a high proportion of fast cars will ensure this

Most car accidents are preceded by a second or of warning During this period the natural reaction behaviour of most passengers can be imagined with description

May I propose the following emergency drill passengers, for consideration by those who h opportunity for experimental examination of the or who have clinical experience of the type of in question? This drill is specifically designed to a injuries to the head and face when passengers are f forwards against the windscreen

The feet are raised and pressed against the d board or against the back of the front seat in the of rear passengers The hands are cupped under t chin, the elbows being wedged in the groins This w prevent whip lash strain of the neck

If this method were to gain medical approval, it m be possible to include it in the Highway Code

Hornchurch, Essex I H J BOURNE

MEDIAN-NERVE PALSY AND ACUTE INFECTIONS OF THE HAND

n,—May I add a similar case to those described by Bailey and Mr Bolton Carter in your issue of ch 12? It is one of 42 cases of carpal tunnel syndrome ted during the last four years, upon which a report ow being prepared

butcher aged 49 was seen on July 7 1953 with a pulp ction of the right thumb which had been drained two s previously He had had systemic penicillin for one before incision and for the next two days, and this was tinued He had much pain in the hand and wrist ravated by extension of the fingers, which were held in the tion of rest Movement of the middle and ring fingers greatly restricted the index and little fingers less so thumb could be moved more freely but this caused some n. Pain at rest was in the median nerve distribution l was severe enough to keep him awake There was tender s on the palmar aspect of the hand over the carpus and st joint with diminution of sensation of light touch but pin-prick over the median nerve distribution in the hand. dorsum of the hand was considerably swollen.

For the previous eighteen months he had had pain in right hand with acroparaesthesiae in the distribution of the dian nerve every Friday night which had repeatedly ken him. On Saturday mornings the hand was stiff and mb with limited finger movement and some residual ugh lessening pain this subsided completely by midday Saturday not to recur until the following Friday night. se symptoms had become progressively worse until he had ely been having pain on occasional nights during the week ficient to awaken him (Butchers are busy in South tralia on Fridays, because they have to prepare large ers for the weekend for a population that eats a lot of at and they do not open on Saturdays.)

In spite of continued penicillin and rest in a plaster back with elevation, the hand grew steadily worse the fingers re immobile and their movement more painful, until lly he could have no finger moved passively into extension hout great pain Sensation loss by July 11 was complete ght touch and much impaired to pin prick over the median ve distribution. Tenderness at the wrist was much reased.

Decompression of the median nerve was therefore done July 12 by longitudinal incision through a convenient mar crease The flexor retinaculum was divided fully nerve was found to be swollen and reddened in the ximal half of the carpal tunnel and relatively narrowed dark red in its distal half A little serous fluid was present there was no abnormality of the tendons. The skin was ly sutured and it healed well Convalescence was slow satisfactory He was back at work in four weeks, although ory loss and strength of the hand did not recover fully four months.

On April 18 1955 he said that he has had no trouble since, hand has remained normal, and his working capacity is mpaired The scar is supple pain free and hardly visible

I feel little doubt that the infection caused an inflam tory swelling in the carpal tunnel which converted a odic occupational carpal tunnel syndrome into a ative emergency I think it probable that Mr Bailey d Mr Bolton Carter's cases fall into the same category

In case 1 there was a history of rheumatism in the ds which may well have been a carpal tunnel syndrome d they mention osteo arthritis in the left hand, which in the pes may be a factor in the production of the syndrome case 2 there is no mention of previous history but it is possible that inquiry might reveal that the patient d previous symptoms of median nerve compression Both these patients fall into the age and sex group most commonly ected by carpal tunnel syndrome—i.e., women at or out the time of the menopause Case 1 had been having nptoms for years and these probably first arose at the time the menopause.

In both of these cases the early and marked loss of sensation is particularly interesting As well as the butcher I have en it in one other patient—a man with a severe carpal jury and projection of part of a fractured lunate into the rpal tunnel His flexor retinaculum was divided and the jecting bone removed three weeks after the original injury but by that time he had complete anaesthesia over the median nerve distribution in the hand which took six months to recover There was acute tenderness over the median nerve at the wrist but apart from some loss of finger movement by mechanical interference, there was little motor impairment.

The restriction of finger movement in all these cases must be due to mechanical interference in the carpal tunnel by compression of the tendons. The dominance of sensory loss seems to be a feature of the more acute lesions in the usual and much less acute carpal tunnel syndrome wasting of the thenar eminence and weakness usually come before definite sensory loss Such patients, however often complain of numbness at the finger tips, especially in the early morning which interferes with knitting and sewing

I agree with Mr Bailey and Mr Bolton Carter that the compression in their cases was the result of inflammatory exudate and consequent ischaemia of the median nerve, but I think that there was a pre-existing lesion which narrowed the carpal tunnel, predisposing to the nerve compression This may in some cases be a stenosis comparable to De Quervain's disease or some other factor possibly hormonal but whatever the predisposing factor the median nerve lies in the carpal tunnel in a particularly vulnerable position In none of my cases has any disability resulted from division of the flexor retinaculum This is not surprising in view of the fact that all strong movements of the human hand occur with the wrist in extension The flexor retinaculum in man seems to be a useless structure

I was interested to read that Mr Bailey and Mr Bolton Carter required a longitudinal palmar incision to be sure of adequate exposure and division of the flexor retinaculum I have tried the transverse wrist incision found it inadequate and reverted to the longitudinal. There are objections to this incision, but in practice they all heal rapidly and well with no disability, especially if carefully made in a crease.

As soon as the diagnosis of median neuritis from compression has been established I make it a rule to divide the flexor retinaculum as soon as possible to avoid the chance of irreversible damage to the nerve. The only exception to this rule is in menopausal women with mild symptoms, which may sometimes be completely relieved by œstrogens. But should there be no improvement within a short time the rule still applies

Royal Adelaide Hospital
Adelaide South Australia.

J D SIDEY

IRON DEFICIENCY ANÆMIA IN PREGNANCY

SIR,—The question of iron therapy in pregnancy is a topical one and articles such as that by Dr Gatenby and Dr Lillie in your issue of April 9 are very helpful in dealing with the practical aspects of this subject

May I make one or two comments on points made by them? It is true that there is a high incidence of intolerance to the ordinary ferrous-sulphate tablets but I have hardly ever found intolerance to enteric-coated ferrous sulphate tablets, so it is to this form of therapy I turn when the former fails. The enteric coated tablet costs only about double the ordinary variety Ferrous gluconate, however I am told costs about ten times as much as the simple ferrous-sulphate tablet This may be worth considering It is true that some might argue that there is a danger of the enteric-coated tablet passing through the gut undissolved especially as the ordinary tablet passes a long way (as demonstrated radiologically) However the clinical response appears to be adequate, so I am not unduly disturbed by this

Another point is in connection with parenteral forms of iron therapy, so widely used now Why should an anæmia discovered late in pregnancy be an indication? All the evidence I have seen shows that the response to oral iron should be as quick as to parenteral iron[1] A quicker response, then, cannot be claimed If one ensures that the patient can take, and is taking, her oral iron, by asking her a few days later, then intolerance of oral iron is no argument Finally, I believe that a form of iron-deficiency anæmia which fails to respond to oral iron is very rare indeed Most of these cases will prove to be megaloblastic if a sternal marrow examination is made

RADIOLOGY OF PLACENTA PRÆVIA

SIR,—Dr Blair Hartley is doing excellent work in using his special technique for visualising radiologically the calcified placenta in localising its position This, he told us in his letter of last week, he can do in rather less than 1 in 3 cases Just in case there are some, among the many who I hope will read his letter, who have not yet been sufficiently convinced of the undoubted merits of ordinary soft-tissue placentography to take it up, I feel I must reassure them that it is quite unnecessary for calcification to be seen in order to determine the placental position

Dr Blair Hartley says that seeing the calcified placenta is factual evidence, agreed, but it would be a pity if those still hesitating to adopt soft tissue placentography became so disappointed at their failure to *see* the placenta in over two thirds of their cases that they did not finally adopt it and thus denied to themselves and their patients the great advantages of the method

The London Hospital, E 1

ROBERT PERCIVAL

FUNCTIONAL SYMPTOMS IN ORGANIC DISEASE

SIR,—In the final paragraph of Dr Barham Carter's somewhat breezy article last week, there occurs this sentence " The great tragedy, of course, is to miss the organic "

It is surely sad that in 1955 it still needs to be pointed out that this attitude reveals a long out dated overvaluation of the soma, and that the tragedy of missing the psychogenic is neither less nor greater but exactly equal to the tragedy of missing the organic

Thirteen years ago an article appeared in *The Lancet*[2] entitled Neurosis Simulating Organic Disorder This dealt with 50 cases which had been referred by Army doctors to an E M S hospital with a definite diagnosis of organic disease, and in which the condition was ultimately found to be purely psychogenic Any case in which even the suggestion of nervous disorder had been raised was excluded from the series

34 of these patients had been admitted to the medical and surgical wards, and constituted 20% of the hospital intake for the 3 months covered by the investigation,

8 of these patients had spent between them 96 weeks in various hospitals and 106 weeks on light duty,

19 of these patients had between them been radiographed 30 times, including 12 barium meals, 2 barium enemas, and 2 intravenous pyelographies,

7 of these patients had received physiotherapy totalling 35 weeks' inpatient and 56 weeks' outpatient treatment

All this staggering waste of professional time and public money was not merely useless to these patients, but actively harmful to them in that it confirmed original fears that they had some serious organic di In many cases it probably made them ther inaccessible to psychotherapy and condemned to a of invalidism

I suggest that this also is a tragic issue I that while both these types of medical error are " the great tragedy " lies in the lack of that bal psychosomatic approach which would make a do is ashamed of missing a psychogenic disorder as he is of missing an organic one

ALAN MCGL

MASKED EPILEPSY

SIR,—I have closely followed the arguments in rel to Dr Wallis's paper of Jan 8 If one agrees that in the leg, cyclical vomiting, headaches, pyrexia, abdominal pain are fairly common manifestation epilepsy, how far does this help in the treatment ? these cases the forerunners of Halhuber's auton dystonias,[1] or the "*Manager-Krankheiten*" of the generation ?

I agree with Dr O'Neill (April 2) and his tension th These cases need more than phenobarbitone Bu exploration of the child's mental state and his env ment must take too long and there are too few psy therapists I look forward to controlled research hypnotherapy Tension appears to be rapidly destro and the child is defended against himself As Bram says[2] " He becomes more in control of his organism

London, W 1

GORDON AMBRO

SANATORIA

SIR,—I read Dr Edwards's letter last week interest While agreeing to a large extent with wh says, I think there is one factor he has not mention namely, that it is quite possible that in the near f patients will refuse to go to sanatoria many miles d from their homes

As regards teaching tuberculous patients " to with their disease," I would say that diabetic pa learn to live with their disease very satisfactorily wi having to go to special institutions for the pu Nevertheless, I quite agree that there is still a place sanatoria in the treatment of tuberculosis, provided are near the centres of population that they serve.

J G HUMBLE

RUPTURE OF LAPAROTOMY WOUNDS

,—In reading Mr Standeven's article of March 12
the subsequent correspondence I have been struck
he lack of reference to what I believe to be a most
rtant feature I have re sutured over 30 burst
mens and in all cases I have noticed the firm
rence of part of the prolapsed bowel or omentum
he edges of the peritoneum and the subcutaneous
es. Surely this suggests that some part of the peri
um has given way at an early stage Small gut or
ntum protrudes and lies just deep to the skin
toneal fluid escapes and (I believe) delays healing
the superficial layers When the skin stitches are
ved the whole wound disrupts and more bowel may
h prolapse

r Standeven and Mr Walsh (March 26) rightly
s the significance of the serous discharge In my
rience this always indicates an impending rupture
uch cases inspection and percussion may demonstrate
t small bowel lies just below the skin

believe that the most important layer of the
ominal wall is the peritoneum Unfortunately it is the
akest If the patient is straining at the time of its
ure the peritoneum may split at right angles to
line of suture In several cases I have found the
ure line to be intact but bowel escaping just lateral
it

doubt if the incidence of dehiscence of laparotomy
unds is in any way influenced by such general factors
anæmia or protein or vitamin deficiency—or even
al sepsis. If the peritoneum stays intact there will
no burst abdomen I feel therefore that Mr
ndeven's distinction between early and late ruptures
an artificial one If the skin stitches are left in till
te the skin edges will probably hold The later a
rst abdomen occurs the more difficult it is to separate
rt of the bowel from the subcutaneous tissues

In my own experience I have found that:

(1) Transverse or oblique incisions are less likely to rupture
an vertical ones because the pull of the abdominal muscles
es not tend to separate the peritoneal edges

(2) The abdominal wall must be relaxed until peritoneal
suture is complete

(3) Nylon is unreliable

(4) Short ends of knots must be left long and the gap between stitches kept short

(5) The peritoneum is less likely to split if a horizontal mattress suture is used

A J WALTON

The London Hospital, E 1

SIR,—Like other correspondents, I found catgut and monofilament nylon unsafe in suturing the rectus sheath Interrupted thread and silk was secure but tedious to insert For three years now I have been using continuous braided nylon (Finlayson's no 6 green) It is pleasant to use and so far safe Although there have been some infected wounds it has only once been necessary to remove the suture

Braided nylon has more elasticity than monofilament nylon so should be less likely to cause the tight feeling in the wound mentioned by Mr Oldham (April 16) This sensation has been mentioned by only one patient but has not been asked for specifically so may well be more common Certainly the knots are unobtrusive

A. M DICKINS

HYPOGLYCÆMIC EFFECT OF DIMERCAPROL

SIR,—Concerning the preliminary communication by Dr Butterfield in your issue of March 5 the papers on sulphur and diabetes mellitus published by Prof Andreu Urra and myself from the medical clinic of the University of Seville are perhaps unknown in Britain These papers were based on a series of experiments which are the subject of my thesis on the problems of sulphur and uric acid in diabetes mellitus[1] Professor Urra and I have also published another paper on sulphur and the metabolism of glucosides in diabetes mellitus.[2] In these investigations, low levels of glutathione were usually found in diabetic blood and experimentally alloxan diabetes was prevented by giving preparations of sulphur We treated diabetics with dimercaprol and found only a slight tendency to reinforce the action of insulin and hyperglycæmia and glycosuria improved

MIGUEL RIOS MOZO

Seville

BURNS FROM ELECTRIC BLANKETS

Mr F Grisley B.SC managing director of the Warm Glow Co Ltd, writes:

In your issue of April 2 Dr Neville Davis reports an accident with an electric blanket To avoid risk of accidents the manufacturers normally instruct the user to switch off the blanket before getting into bed but people often disregard this advice Alternatively a waterproof sheet may be used between the blanket and the sleeper This also may be disregarded, or a worn or pervious sheet used with disastrous results. The use of an earth as suggested by Dr Davis, is impracticable and even dangerous for the blanket should be an earth free appliance with no exposed metal parts.

In 1948 my company introduced a plastic-covered waterproof element into all our blankets. This not only prevents danger from bed wetting, but it also enables the whole blanket to be immersed for laundering The plastic covering used is stable and flexible, and lasts indefinitely This particular kind of accident therefore need never occur

PLASTIC APPLIANCES MOULDED DIRECT TO PATIENT

Mr R A E. Walker secretary of the National Research Development Corporation writes

In his article of April 23 Dr Brennan refers in a footnote to patent application no 10609/51 It may not be clear to your readers that this application relates to the proposals communicated to us by Dr J T Scales of the Institute of Orthopædics Royal National Orthopædic Hospital Stanmore for the preparation of composite material of 'Polythene (polyethylene) and Moltopren (polyurethane) and the moulding of surgical splints therefrom by application to plaster casts or directly to the patient The patent rights in Dr Scales's invention have been assigned to the Corporation for exploitation in accordance with the Development of Inventions Act 1948 Application may be made to the Corporation for further particulars.

Obituary

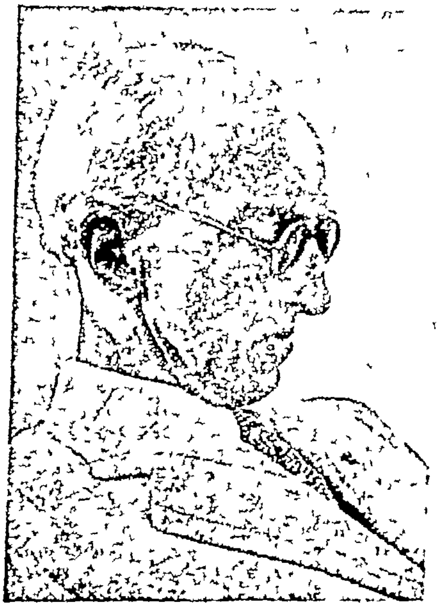
EGBERT COLEBY MORLAND

M B, B Sc. Lond, M D. Berne, F R C P, F R C S
EDITOR OF THE LANCET, 1937-44

In the development of a journal a few men and women play outstanding parts The influence of Dr Morland's original mind and new points of view was apparent from the time he joined the staff of *The Lancet* in 1915, and it continues through those he taught

In few ways an ordinary man, he brought to his main task a knowledge and experience as unusual as it was useful

He was born on Sept 3, 1874, the fifth son of Charles Coleby Morland, J P, of Croydon, and his wife Jane Fryer The Morlands and the Fryers were Quakers from the North of England, and the Croydon family was both brilliant and unconventional Egbert, a clever but uneasy boy, was sent to the Whitgift Grammar School and then to Bootham, the Friends' school at York. A taste for science was confirmed by a period at Owens College, which also gave him a lifelong bond with Manchester He took his B SC with first-class honours in zoology, and went on to St Bartholomew's Hospital with a senior scholarship At Barts he won the Matthews Duncan prize and was vice-president of the Abernethian Society, and after taking the London M B in 1898, with the gold medal in physiology and honours in anatomy and organic chemistry, he became successively ophthalmic house-surgeon and house physician at his own hospital, and house-physician at Wolverhampton General Hospital His next appointment, in 1901, was at Great Ormond Street, and it was then that the natural sequence of his career was rudely broken He developed tuberculosis



Like many another medical victim of this disease, he presently found himself making it his special study The first fruit of this new interest was an essay on the design of sanatoria, entered for an international competition held in 1902 before the King Edward VII Sanatorium was built at Midhurst There were 180 competitors, and with the aid of his architect brother Morland gained third prize for his plans, which were published in the first issue of *The Lancet* for 1903 The new phase in his life was soon established, for after living for a while in Switzerland to recover his health he decided to remain and make his home in the mountains In 1903 he married Mary Windsor Latchmore, a woman of zest and character who helped him devotedly till her death in 1948, and when he had taken the Swiss Federal Diploma they settled at Arosa, where he practised in three languages and from 1907 to 1914 directed the Villa Gentiana, an English sanatorium In 1905 he was writing in these columns, with W R Huggard, on the action of yeast in tuberculosis and its influence on the opsonic index, and his M D thesis at Berne in 1907 was on opsonins—a subject then in the bacteriological forefront From the German he translated Turban's *Diagnosis of Tuberculosis of the Lung* and Bandelier and Roepke's *Tuberculosis in Diagnosis and Treatment* In 1913 he produced a small book, written with Clive Rivière, on *Tuberculin Treatment*, and a paper on technique of artificial pneumothorax

This phase was ended by the outbreak of war, and next began almost by chance Now some 40 years he left Switzerland to join in the Society of Fr relief work on the Marne Before doing so, however, had displayed his journalistic talent by abstracting *The Lancet* a statement by Paul Eltzbacher on food supply of the German people, and when twenty-column contribution arrived one day ju the journal was going to press, the editor had paid compliment of holding back the week's issue until it be included When Morland returned to London the Marne and called at the old *Lancet* office at the co of Bedford Street and the Strand, Sprigge wa difficulties because Gerald Horner, then assistant ed was serving in the R.A M C, so he said to Mor "why not stay and help?" And Morland sta for 29 years

At this point one might follow the precedent of Hebrew biographer who referring his readers to the b of the Chronicles of the King Israel and Judah But though bound volumes of *The La* since 1915 contain most of acts of Morland, and would h been very different without h what he did himself is inextrica mingled with what other peo did In an effort to analyse influence it has been truly that he found the journal hum but left it human, but perh his greatest effect on our colu was one of refreshment He this effect because he was artist and (to the end of unexpectedly long life) a petually surprising person

The artist enables people to familiar things anew, and land had just this faculty angle of vision always seemed be a little different, and, th this often embarrassed and so times alienated his acquaintan it helped him to be not only an animating journa but an exceptionally valuable member of our profess for to look at things at a new angle is often hig instructive He also had the catholic curiosity of investigator and was ready to be thrilled by any fr thought or fact—though he might lose interest quickly When he wanted to do so, he could absorb body of knowledge very thoroughly, and he rememb a great deal about a great many diverse subjects, fr mathematics to midwives, from infant feeding to European flora, but he had little intellectual taste generalisation, and tended to look at one thing at a ti "on its merits" Hence, as an artist, he preferred t small canvas to the large one, and he enjoyed paint detail But whether the canvas was large or small, would avoid monotony by an engaging touch inconsequence in the composition

If this is not the portrait of a creative thinker, it nevertheless the portrait of a born journalist, born make others think Moreover, in this delicate and of exhausted man—the "old poitrinaire" as he call himself—the mental liveliness was matched and ma profitable by an astonishing capacity for work, day day out, year in year out Skimming, as it seem through the millions of words that poured into th office, he could quickly detect what was new and intere

Morland, when he wanted, could write so catalytic a letter as to draw a contribution from the most unreactive of experts, and even his routine communications were carefully written in a personal way—often in fact by hand But it cannot be said that even through the post he wholly satisfied everybody , for ordinary people often prefer ordinary letters, and few besides harassed editors know how correspondence may improve if allowed to " mature " Those who went to *The Lancet* oracle with a question must be prepared for an oracular reply, which left the " onus " (to use another of Morland's favourite words) on the person receiving it The following, for example, is his answer to a long letter from a doctor who wanted to know about the copyright regulations governing the reproduction of *Lancet* material in foreign broadcasts

Dear L ,

I am glad to hear you are helping the British Council to let South Americans know what British medicine is doing We do our own bit too I don't feel I can give you any general guidance on copyright in the air But you would find the Golden Rule applicable and between ourselves the Hippocratic Oath is binding

With kind regards, Sincerely Yours,

EGBERT MORLAND

Copyright was one of the subjects that did not interest him

Even his colleagues seldom had their questions answered directly or comprehensively But when his mental processes seemed to be at their most devious and detached the probable reason was that he was not yet ready with his decision, which he would give in his own time and his own way It was partly because he was so puzzling that he was so fine a teacher , and, whether amusing or infuriating, his enigmatic instructions somehow extracted from his juniors the same kind of effort that he himself put into *The Lancet*

Nor did this taste for the oracular prevent his being energetically practical in other fields when something within his compass needed to be done Hence in his spare time (which did not exist) he did solid work in many useful causes , and in various ways he was of service to the Queen Alexandra Sanatorium at Davos, to the Enham (now Enham Alamein) Village Centre for Disabled Ex Servicemen, to the Medical Defence Union, to the Society for the Relief of Widows and Orphans of Medical Men, and to Sibford School, of which he was a governor But, though a good speaker, he seldom appeared on platforms or at the meetings or dinners of medical societies Disliking public occasions, he was inclined to think that an editor should be a back-room boy, neither seen nor heard except through his journal, and invisible especially to callers None the less he was a sociable person, and never more happy perhaps than in the Athenaeum, which likes a proportion of its members to have their eccentricities He was happy, too, in the fellowships conferred on him by the Royal College of Surgeons in 1936 and the Royal College of Physicians in 1941 , though both colleges probably wanted to withdraw their honours when they saw that he described himself (whether to save space or out of modesty) as FRCP&S

When Morland succeeded to the editorship in 1937 he was already 62 , and two years later, when war broke out and the decision was reached to move the journal out of London, he was tempted to resign his sisyphean task But, as it turned out, the move to Aylesbury proved a tonic Settled cosily in a flat above the tiny office in Temple Street, he abandoned even the convention of office hours and did most of his downstairs work after supper when his juniors had gone home Freed from the social obligations of his chair, and disguised from former friends by a beard and a dilapidated mackintosh, he took an eager interest in the war-time life of the small market town, and spent more of his time in reflection and reading—though even now he never finished a b preferring the random sample With a senior's less of inhibitions, he was finding it easier to show abundant kindness of heart and concern for oth but to keep the balance he showed also more of sharpness of his tongue When directed towards rather than individuals, this asperity was gene enjoyed, and it is pleasant to find in our files his de comment on a rather pompous declaration in distinguished signatories defended the rights and l of the citizen Underneath, in his small, neat, decor hand, Morland has written

I'd rather be in prison with my friends th free with that lot. Ed. L.

It was sad, in a way, that he should not take comm of his journal until his most active years were p for he never got full credit for his achievements, these were different from what they might otherwise h been But possibly *The Lancet* did not lose ther for in his more impetuous moments he often nee someone to tell him to think again Moreover, tho he could rule both by love and by fear, he was not a b commander he was a prophet or priest rather th king—an impish prophet but in direct line from the Testament During the war he was already an old with the defects of his high qualities becoming apparent, and it was inevitable that in his cour Aylesbury the executive responsibility should dev more and more on his lieutenants—as once it devolved from Sprigge to him So the honour burden was partly transferred to younger shoulders, when *The Lancet* returned in 1944 to London Mo retired into private life—with a characteristic valedic greeting to his readers

At first at Aylesbury, and afterwards in an old s house beside the ancient Friends' meeting hous Wooldale in Yorkshire, he adjusted himself yet aga new circumstances He had given much thought to age—its disabilities and possibilities—and had m been one of the first to see the need for a conc movement for old people's welfare, comparable complementary to the movement for infant welfare w developed during and after the previous world war 1945 he expressed his ideas in a charmingly Morla pamphlet called *Putting Them on the Map,* written f Buckinghamshire committee of which he was instiga member " We must search out the old people in t hidey-holes," he said, " and find for ourselves whe they are content with their lot, whether it is a lot which they should be content, and if not what we sh do to amend it " Himself, he well understood the v of continuing to be active, and as lately as 1951 he w the biography of a pioneer midwife, entitled *Alice and Stork* He had the advantage of being one of those wh pleasures are of the mind, and for some years of retirement he was also fortunate in his keen enjoym of gardening and walking, and in the companionship his wife But each in turn was taken from him, eventually almost all the power of sight By refinement of age, and its distresses, his face bec less that of a prophet than a saint—a rôle to which had never aspired One of his chief hopes, he said that he might continue to amuse those around him.

He died at York on April 26, in his 81st year even to the last his mind, though wayward, reta the ardent quality that so often made him seem youngest, though maybe also the oldest, of his comp Throughout his life he belonged to the present and future rather than the past , and many who knew h as well as many who did not, have cause to be grat for his disturbing, enlivening, and enlightening spirit

WILLIAM BURRIDGE

D.M. Oxfd

Dr William Burridge formerly professor of physiology d principal of the King George's Medical College and n of the faculty of medicine at Lucknow University d in hospital at Dartford, Kent, on April 21, at the of 69 He was the author of *Excitability a Cardiac dy* (1932) *A New Physiology of Sensation* (1932) *New Physiological Psychology* (1933) and many short les in various journals.

A T B writes 'Like his fellow Cornishman mphry Davy, and his pupil Faraday Dr Burridge de important discoveries through brilliantly original periments using very cheap and simple apparatus s book *Excitability* describing his experiments on frog's heart is a medical classic, and this study the beating heart's responses to stimulation enabled n to correlate similarities in nervous action and con ous sensation to deduce rhythmical activity in brain d spinal cord neurones and in sensory end-organs and elaborate many logical consequences of assuming ythm in neurones. The fact of rhythm in cerebral urones has since been independently confirmed by er workers some of his predictions remain to be oved by experiment.

"So far Dr Burridge's work has not received the eral acclaim it deserves. We owe to him the new d revolutionary concept of responsiveness as distinct m excitability, a new method of research in pharma logy, giving new and surprising information on the ltiple actions of some drugs and their quite different ects in large and small doses and a new physiological chology harmonising experiment, sensuous experience d deductive reason and well in advance of any previous ory of sensation and of thinking process.

His own explanation of the opposition that his work d theories met was the power of an orthodox primary umption to blind fully organised minds to any new th that contradicted teaching elaborated from the mary falsely generalised preconception His Puck ing the Doctors (*Medicus* December 1952) gives a l statement of his defence and repays reading

PATRICK KERR DIXON

M.D Dubl. F.R.C.S.I

Dr Patrick Dixon who died on April 21 at Lusaka rthern Rhodesia, had spent nearly thirty strenuous and venturous years as a medical missionary in the Belgian go.

He was born in 1898, the son of the late Andrew on, professor of anatomy and dean of the school of ic at Trinity College Dublin Patrick's studies Trinity College were interrupted by the 1914–18 r and he was mentioned in despatches for services th the Royal Garrison Artillery in France In 1918 returned to Dublin to graduate in 1922 in science, h first-class honours in mathematics and experimental ence. Two years later he graduated M.B with honours. In 1926 he joined the Garenganze Evangelical Mission the Belgian Congo

For the next twenty five years, despite the effects of re injuries sustained when he was mauled by a lion, he rved the people of the Luapula Valley with devotion the course of his work he saw the suffering caused by choma and in 1920 he visited India to study this ease under Sir Henry Holland His published work ls with his experience of its treatment in Central Africa. e hospital which he founded at Chibambo became a ntre for the treatment of eye diseases. In recognition of services he was decorated by the King of the Belgians. In 1932 ill health forced him to leave the Luapula alley, and for a time he was medical officer at Nkana ine In 1933 he joined the staff of the Government frican Hospital at Lusaka He also taught at the frican Medical School

A colleague writes: 'Pat Dixon was an eager tireless d devoted worker, content to make do with the most eagre equipment yet keeping himself up to date in the edical world and always looking forward In this he as a true disciple of the great Dr Livingstone who had amed the same country fifty years before Like him o, Dixon bore to his dying day the marks of the lion's unch in his left humerus. He will long be remembered on the divide between Congo and the Zambezi watersheds'

His first wife, Miss Olive Arthur died in 1927 In 1934 he married Miss I H Russell who survives him with a daughter of his second marriage

KENNETH BENSON BELLWOOD

O.B.E., B.A, M.B Camb., F.R.C.S.

Dr Bellwood consultant surgeon to the ear nose and throat department of Bedford General Hospital, died at his home on April 17 at the age of 64

He was born in Middlesbrough and was educated at Coatham School, Redcar He was a scholar of Pembroke College, Cambridge, where he took the natural sciences tripos in 1912 and a Shuter scholar at St. Bartholomew's Hospital qualifying in 1914 During the 1914–18 war he was appointed O.B.E. for outstanding service in the Royal Navy In 1917 he took his M.B Soon after he returned to civilian work he entered general practice in partnership with the late W H Miller in Bedford and also specialised in diseases of the ear, nose, and throat. In 1921 he obtained the F.R.C.S. When in 1930 he was appointed E.N.T surgeon to the Bedford County Hospital he laid the foundation of the present successful large and busy E.N.T department at the Bedford General Hospital Despite ill health which first showed itself in 1940, he worked indefatigably, and he was appointed consultant surgeon to the department when the hospital was taken over by the National Health Service in 1948

G A M writes: 'Dr Bellwood, as he is called by all in Bedford was loved for his quiet modesty and great kindness to all his patients The greatest sorrow will be felt by the patients he looked after as a general practitioner He loved the hills, and was a great walker in his day Even when he could no longer climb he always went north to his beloved Yorkshire for his holidays'

In 1921 Dr Bellwood married Florence Violet Cooper, who survives him with two daughters

Notes and News

HEALTH EDUCATION

AT the seminar for public health workers organised by the Central Council for Health Education of Great Britain and held in London from April 19 to 23, delegates attended from 21 countries Dr W Emrys Davies, education officer to the council, said that people do not listen to instruction unless they feel that the subject matter is relevant to their own problems and way of life Hence the first task of the health educator is to assess the basic human needs common to all, in any country, whatever the conditions or climate The second is to establish an atmosphere in which discussion can flourish, and experiments have shown that the discussion group can achieve what its members could not achieve singly The group leader is therefore a more effective person than the lecturer talking to an audience and isolated from his hearers by natural barriers of platform position, shyness, and absence of communication of ideas between members of the audience Dr John Burton, medical director of the council, described the use of case histories which command interest from members of a group and which recall to many experiences that can be used as a basis for discussion Mr W Sellers, film advisor to the Colonial Office, said that in dealing with illiterate people one must evolve three dimensional visual aids which come within the range of their everyday experience Diseases have to be classified in relation to their causes and source—e g, insect infections, airborne and water borne diseases In Nigeria a film van has proved a big attraction because people will comprehend a moving picture when the still one makes no impression

UNDERGRADUATE TEACHING IN LONDON

THE difficulties of undergraduate teaching hospitals arising from the shift of population from the centre of London are mentioned by Colonel J J Astor, chairman of the board of governors of the Middlesex Hospital, in the hospital's statistical report for 1954 At the Middlesex the bed occupancy rate is over 90%, and the pressure on the outpatient department is as great as ever, but " there is a tendency for clinics and wards to be deprived of various types of case which are valuable for undergraduate teaching Patients suffering from these conditions are now for the most part being treated at hospitals in the peripheral areas, and in consequence medical students of today are not seeing the cross section of illnesses which was available for their predecessors when this was still a residential area " As an interim measure the Middlesex has arranged with the Luton and Dunstable Hospital for some of the patients on that hospital's waiting list, with their consent, to be transferred to the Middlesex for treatment, and this scheme is working well

"THREE MEN" [1]

Miss Jean Evans, a writer who has turned her talent to presenting the case histories of three living men, describes her book in a sub title as "an experiment in the biography of emotion" Johnny Rocco began life as a rejected child who was often delinquent, but who has finally made a precarious social adjustment William Miller, too, was often delinquent till he became blind, he recovered his sight but (perhaps finding the responsibilities of sight too heavy) became delinquent—and blind—again Martin Beardson is a tormented homosexual She tells their stories with sympathetic insight, but without interpreting the psychological mechanisms at work. It was inevitable that she should select, from the vast quantity of material she has amassed in the course of her long and friendly association with these men, which facts and which letters and conversations to report, but she has a biographer's skill in choosing what is relevant, and the reader is confidently aware that the picture is true, distorted neither by compassion nor censure Prof G W Allport, professor of psychology in Harvard University, notes in an introduction how valuable he has found the book in the teaching of students Because Miss Evans has avoided imposing her own interpretations, students are stirred to ask questions, and hence to discover much about some common forms of mental sickness. "The first requirement in good teaching," as Professor Allport says, "is to excite greedy curiosity" These cases, he finds, do exactly that

University of Liverpool

At a recent examination for the diploma in tropical med and hygiene the following were successful

P B Acharya, A A Akiwumi, S H Bokhari E J M A Jafri Prakong Kecharanantana N H Khan T J Ma J I Maxwell, H Medina P A Y Narayanan Margaret C Bridget O'Keeffe, A V Rao, J B Roy, G Singh, S

Dr J B Roy has been awarded the Milne medal in medicine, and Dr J I Maxwell the Warrington Yorke in tropical hygiene

Royal College of Physicians of London

At a comitia held on April 28, with Sir Russell Brain, president, in the chair, the following were elected to fellowship

J F LANDRETH Christchurch New Zealand, J L Fra London J H HALLIDAY, Sydney, R I MACDONALD, To F E PILKINGTON, South Brent, Devon, R L WATE London, A C STEVENSON, Belfast, H A TREBLE, Cante J C RICHARDSON Toronto, J F LOUTIT, Harwell, T E Newcastle upon Tyne, R B KERR, Vancouver, R N TATTE Leeds, A C DORNHORST London, W S SUTTON Liver B G PARSONS SMITH, London, F H SCADDING, London, LEIGH London, H V MORGAN Khartoum, L D W S Glasgow, D A WILLIAMS, Cardiff, C F HAWKINS Birmin R D TONKIN, London H P WILLIAMS Coventry, A WILLIAMS Kampala, J R ELLIS London R A JONES Cambs, E K CRUICKSHANK, St. Andrew, Jamaica, MACDONALD, London B G MAEGRAITH, Liverpool, W A KARUNARATNE, Colombo

The following were elected to the fellowship under by 39b, which provides for the election of non members " have distinguished themselves in any branch of the sc or practice of medicine "

I DE B DALY F R S, Cambridge, K G V NYLIN, Stock W G PENFIELD, O M, F R S, Montreal, G F STRONG Vanco

The following, having satisfied the censors' board, elected to the membership

stitute of Cardiology, London

Dr. Lawson McDonald has been appointed assistant rector of the institute

Dr McDonald who is a graduate of the University of Cambridge lified from the Middlesex Hospital London, in 1942 After olding house-appointments there he served in the R.N.V.R. om 1943 to 1946 From 1946 to 1948 he held various appointents at the National Heart Hospital and the Institute of Cardiogy. In 1948 he returned to the Middlesex Hospital as medical gistrar and in 1949 took the M.R.C.P Later he was appointed sistant to the professor of medicine at the Middlesex Hospital, d visited Stockholm in connection with research into peripheral scular disorders He graduated M.D in 1952 He was awarded Rockefeller travelling fellowship for 1952–53 and during its tenure worked in Boston His publications include papers on peripheral scular disease ischaemic heart disease and mitral-valve disease th special reference to the pulmonary circulation and to surgery the mitral valve

ommonwealth Health and Tuberculosis Conference

Mr Iain Macleod the Minister of Health will open this nference at the Royal Festival Hall London, on June 21 her speakers will include Dr Johannes Holm (W.H.O.) r P V Benjamin (India) Prof Etienne Bernard (France) r Walsh McDermott (U.S.A.) Dr E Ross (Canada) r H G Trimble (U.S.A.) Prof Arvid Wallgren (Sweden) r Geoffrey Marshall Dr George Day and Dr Honor Smith. urther particulars may be had from the National Association r the Prevention of Tuberculosis, Tavistock House North ondon, W.C.1

eview of Byssinosis Benefit

The Minister of Pensions and National Insurance has sked the Industrial Injuries Advisory Council to review the rovision made for byssinosis under the National Insurance Industrial Injuries) Acts. This review is being undertaken r the council by their industrial diseases subcommittee The chairman of the subcommittee is Sir Arnold Plant and e members include Prof R E. Lane F.R.C.P

Regulations made under the Industrial Injuries Acts at present ovide insurance cover against the disease for people who have en employed at some time since July 5 1948 and for at least enty years in all, "in any occupation in any room where any ocess up to and including the carding process is performed in ctories in which the spinning or manipulation of raw or waste tton is carried on." Benefit is not, however, available unless the rson concerned has died from byssinosis or his disablement from e disease is assessed at not less than 50% and is likely to be rmanent These conditions were imposed because of the difficulty distinguishing byssinosis from bronchitis and emphysema of non-occupational origin.

Persons and organisations are invited to submit written vidence to the secretary of the council 10 John Adam Street London W C.2 not later than June 6

Institute of Hospital Administrators

The annual conference of this institute will be held at Caxton Hall Westminster S W 1 from May 12 to 14 The principal subject chosen for discussion is Group Administration.

British Association of Physical Medicine

At a meeting held on April 23 the following officers were elected for 1955–56:

President Lord Horder vice president Dr W S Tegner; hon. treasurer Dr A C. Boyle hon secretary Dr G O Storey; hon editor Dr H A Burt

The Medical Sickness Society

On April 26 a reception was held by the Medical Sickness Annuity and Life Assurance Society Ltd. to mark the opening of their new offices at 8 Cavendish Square London, W 1 The guests were received by the chairman, Mr R. McNeill Love

Royal Statistical Society

Study Circle on Medical Statistics—The annual general meeting of this circle will be held on Tuesday May 31, at 5 45 P.M. at the Westminster Medical School, Horseferry Road S W 1 Afterwards Dr P Armitage Dr John Knowelden, and Dr R F Wrighton will read short papers on Controlled Trials in Medical Research

Shortage of Dentists

The Interdepartmental committee under the chairmanship of Sir Arnold McNair, which has been set up by the Minister of Health and the Secretary of State for Scotland to ascertain the reasons for the lack of candidates for training as dentists, has held its first meeting and is ready to receive evidence Persons or organisations wishing to give evidence should in the first instance communicate in writing with the secretary of the committee, Mr T C L. Nicole at the Ministry of Health Savile Row London, W 1

Food Hygiene Advisory Council

On May 2 Mr Heathcoat Amory the Minister of Agriculture Fisheries and Food announced that 11 members of this council are to represent the public 3 the trades, and 3 the workers in the trades. Lord Strong is to be chairman and other members include Mr S W Barnes, secretary to the governors of King's College Hospital Sir Harry Sinderson, F.R.C.P.E director for Sussex of the St John Ambulance Association, and Mrs. James Tweed, chairman of the house committee of St James's Hospital Balham.

Dr Stott Commemoration Fund

This fund has been started as a tribute to the work of Dr L B Stott who until his retirement owing to ill health last December spent 33 years as medical officer at Papworth Village Settlement. In view of his interest in children it is proposed to use the fund for prizes or grants for children at Papworth Village or school and/or a shelter in their playing field

Contributions should be sent to F E Redman secretary of the fund St Peter's Hostel Papworth Everard Cambridge

Haemophilia Society

The annual general meeting of this society on April 24 was attended by 60 members and a number of doctors interested in haemophilia Sir Lionel Whitby F.R.C.P was re-elected president and Dr R G Macfarlane was invited to become a vice president Reports on the work of groups in the South of Scotland Manchester Newcastle Sussex and Middlesex were received During the past year the society had sponsored the formation of similar societies in Australia France Holland, and Switzerland. Its address is 94 Southwark Bridge Road London, S E.1

Hospitals in Eire

The second of three sanatoria which the government of Eire is building was opened at Blanchardstown co Dublin by Mr T F O'Higgins, the minister of health on April 22 The west regional sanatorium at Merlin Park, Galway was opened in 1952 and the southern regional sanatorium will be opened next month The hospital at Blanchardstown will be known as the James Connolly Memorial Regional Sanatorium It has cost £1¾ million, and it will accommodate 520 patients

It is laid out in seven 40 bed pulmonary blocks a 40 bed isolation and infective children's block four 30-bed non-pulmonary blocks (including orthopaedic) and a three-storey hospital and treatment centre with operating theatres and X ray and physiotherapy departments with 80 beds The group of buildings on the 240-acre site also includes a nurses home for 100 nurses and houses and flats for the medical staff

International Society of Criminology

The third congress of this society will be held at Bedford College, London, from Sept 12 to 18, under the presidency of Dr Denis Carroll Further details may be had from the organising secretary, Mr H O Cox, 28, Weymouth Street, W 1

Indian Medical Services Dinner Club

The annual dinner of this club will be held at the East India and Sports Club Ltd , St James's Square, London, S W 1, on Friday, June 10, at 7 30 P M Tickets may be had from the secretary of the club, Medical Board Room, Commonwealth Relations Office, Matthew Parker Street, S W 1

Food Microbiology and Public Health

During its summer conference and annual meeting in Cambridge the Society for Applied Bacteriology will hold a symposium on this subject on July 4 and 5 This is open to non members, and further particulars may be had from Mr G Sykes, the hon secretary, Boots Pure Drug Co , Ltd , Microbiology Division, Nottingham

Kashmir Medical Congress

Arrangements are being made for a party from this country to attend a medical congress in Kashmir next November The approximate cost of £298 per person will include return air fare from London and travelling and living expenses in India Further details may be had from Dr R U Hingorani, 128, Harley Street, London, W 1

International Association of Gerontology

The fourth congress of this association will be held in It early in September, 1957

Vitamin E Congress

This international congress will be held in Venice Sept 5 to 8 at the Cini Foundation on the Island of Giorgio Maggiore Further details may be had from secretary, Prof Emilio Raverdino, Via Pietro Verri 4, Mi

National Insurance Benefits Abroad

People otherwise entitled to National Insurance retire pensions, widows' benefits, or guardian's allowance will able to draw their benefit in any country in the world if dra regulations submitted to the National Insurance Advis Committee are approved At present these benefits ca be paid to people resident abroad only if they are living in the Commonwealth or in the Republic of Ireland

---

The British Standards Institution have published a new sta (B S 2606) specifying requirements for flexible lead rubber g for X ray workers Copies of this standard may be obtained fr the institution's sales branch, 2, Park Street, London, W 1, pr 2s 6d

CORRIGENDUM *Hydrocortisone in Lesions of Soft Tissue*—In article by Dr Crisp and Dr Hume Kendall (March 5) the form of hydrocortisone was wrongly given The positions of the –O and – CO CH$_2$OH groups attached to the 17 carbon atom sh be reversed

PITAL BOARD ; PHYSICIAN DEPARTMENT OF PSYCHO
GICAL MEDICINE UNIVERSITY COLLEGE HOSPITAL, LONDON

m the South East Metropolitan Regional Neurosurgical Centre

In the latter part of 1949 working with Dr Ström sen at the Runwell Hospital one of us (G C K) was le to introduce to this country the operation of orbital dercutting devised by Scoville in 1948 In 10 patients ho had not benefited from leucotomy the operation re results which in Dr Ström Olsen s opinion, justified extension to cases of neurotic tension, in which Scoville d claimed success

During 1950 orbital leucotomy was used in association th Dr Ström Olsen and Dr Bierer and since 1951 re than 50 such cases have been operated on at the uth East Metropolitan Regional Neurosurgical Centre the Brook Hospital Blackheath Elsewhere other difications of the original leucotomy have been per rmed, and Sargant (1953) has drawn attention to their ue He recommended their use in intractable ychosomatic states in anxiety hysteria and in anxiety d depressive states in obsessional personalities ' and pointed out that other forms of treatment notably chotherapy might succeed after operation though y had failed before.

The results *obtained by our modified orbital operation* peared so encouraging as to warrant a closer analysis the patients psychological condition and we have efore collaborated in this interim report The only vious English survey of orbital leucotomy is that of and Lewin (1953) of 20 cases operated on chiefly the late Sir Hugh Cairns at Oxford

Our review covers a consecutive series of 59 patients rred by various psychiatrists, usually because they such anxiety or depression that life was a misery being asked by letter to attend for follow up 4 did not y and remain untraced 3 others had undergone cotomy previously and were therefore excluded from survey Of the remaining 52 40 were British and Polish and all save 4 had been ill for more than two rs—several of them for more than ten years

Basis of Surgical Treatment of Mental Disorder

(G C K)

The surgical treatment of mental disorder began with e injection of alcohol into the frontal lobes and has dually developed into localised anatomico physio ical investigation yielding fresh information about the chanisms of emotion and the intellectual activities the frontal regions. Our knowledge of these matters mains imperfect and the investigation continues.

The effects of the full standard leucotomy dividing central core of white matter within the frontal lobe owed that it was preferable to limit a leucotomy incision the lower segment particularly to the lower and er fibres within the frontal lobe so as to maintain the cessary reduction in emotional tone while minimising associated intellectual deficit

Precise electrocoagulation of the dorsomedial nucleus the thalamus (Spiegel and Wycis 1949) has shown that all the effects of leucotomy may be produced by a lesion strictly localised to one area of the brain from which the afferent connections proceed to the frontal cortex

Our knowledge has been increased by experiments on individual projection pathways either by excision of limited cortical areas (cingulate superior convexity and orbital) by topectomy, and by undercutting similar areas leaving the cortex intact but severing the afferent and efferent fibres passing to and from the selected zones All these methods are intended to modify emotional behaviour while minimising concomitant damage to personality and intellect

Many of these later modifications of technique were developed because of our appreciation of the importance of the thalamocortical connections. Le Gros Clark and Boggon (1933) and Le Gros Clark (1948) have shown that a large part of the frontal cortex is an afferent projection area for the dorsomedial nucleus of the thalamus, comparable with the projection areas of the visual and auditory areas of the cortex, there being a well-defined point to point projection of fibres in which the anteroposterior axis of the dorsomedial nucleus projects in serial order on to the anteroposterior axis of the frontal lobe, to the cingulate superior convexity and orbital surfaces Since the dorsomedial nucleus of the thalamus is essentially a relay station for the transmission of impulses originating in the hypothalamus, the frontal cortex seems to act in part at least as the projection area for fibres concerned with hypothalamic activity and of obvious importance in emotional integration The later developments of surgical technique have concentrated on interrupting certain of these connections alone while leaving the remainder of the frontal cortex undisturbed

Preceding accompanying and giving impetus to these surgical assaults there has been a gradual change in our conception of the nature of intellectual and emotional activity No longer is intellectual function regarded as purely cognitive dependent upon the perfect function of the cerebral cortex working in isolation, and independent of any influence ascending from the basal areas of the hippocampus and hypothalamus, which are concerned in autonomic and emotional activity in the affective sphere It has come to be realised that the function of the cortex *may be profoundly disturbed by stimuli* ascending from the basal areas of the brain

Dana (1921) and Cannon (1927) suggested that emotion resulted from the action and reaction of the *diencephalon* and the cerebral cortex the diencephalon, having received sensory impulses associated with *emotion* would discharge upwards to the cerebral cortex impulses which gave rise to emotional experience or subjective feeling at the same time as it would discharge downwards the motor impulses which produced emotional behaviour

Nathan (1931) held that emotion and personality were localised in the *region of the third ventricle* and traced the development of this theory from the work of earlier observers.

Alford (1933) thought that emotion and consciousness were particularly disturbed by basal lesions in the left cerebral hemisphere

Papez (1937) pointed to the *ensemble formed by the* hypothalamus gyrus cinguli, hippocampus and their various connections, and regarded these as *the probable* anatomical substratum of the emotions. In elaborating this theory he displayed the wide connections that exist between the thalamus hippocampus *and hypothalamus* and between the thalamus gyrus cinguli, and frontal cortex In discussing the hippocampus he pointed to the absence of evidence of olfactory function in this area, and drew attention to the facts *that in rabies* the Negri bodies are most abundant in the large ganglion cells of the hippocampus and the patient shows intense emotion and hyperaesthesia to all forms of stimuli with the result that all stimuli provoke fear sometimes mingled with rage

In Papez's view somatic (including visceral) impulses entering the circuits of these basal areas may obtain emotional colour and finally reach the cortical level as "a stream of feeling" modifying the function of the cortical regions This theory suggests that the pathways connecting the thalamus to the orbital cortex and other regions of the frontal lobe contain the afferent projection systems for emotion, and it is noteworthy that each of the cortical areas receiving such pathways gives rise to efferent fibres passing towards the hypothalamus which could constitute the pathways for *emotional reaction* As Le Gros Clark (1952) has stated

> "It has come to be realised that intellectual and emotional processes are so intimately interlocked in any form of mental activity that it is not possible to separate them even as arbitrary categories Intellectual processes are only capable of normal expression if they are activated and directed by the driving power of emotional processes, The cerebral cortex may be structurally intact but its function can be grossly deranged if it is thrown out of gear with those more primitive parts of the brain which provide neural bases of emotional reaction"

In extending the surgical treatment of mental disorder to the sphere of the neurotic and psychoneurotic it is to the relief of an abnormal emotional charge disturbing the function of intelligence that the treatment appears to be most directly applied We seek a method which will produce the greatest modification of emotional tension without associated injury to intellectual pathways

Scoville (1949) has described the techniques for undercutting each of the three cortical areas—cingulate, superior convexity, and orbital—to which fibres radiate from the thalamus That the orbital technique is the most likely to lower neurotic tension without causing a serious intellectual deficit is suggested by the observations of Rylander (1939) which indicate that lesions of either the orbital or the inferior aspect of the frontal lobes produce changes in emotional tone rather than in intellectual or psychomotor activity Rylander (1952) in particular has shown by psychometric studies that lesions on the superolateral aspect of the frontal lobe are more likely to produce intellectual disturbances Experimental evidence also shows that stimulation of the orbital areas produces autonomic responses, and ablation of those areas tranquillity or loss of fear

Scoville's techniques were fully described and illustrated at the International Congress of Psychosurgery held at Lisbon in 1948, and subsequently published (Scoville 1949) Scoville states that he aims to undercut the entire orbital surface, including the prechiasmatic area, isolating the entire cortex over the orbital plate as far back as the level of the anterior clinoid process on the inner side, and as far laterally as the junction of grey and white matter on the lateral aspects of the lobe We have deliberately modified this method, omitting the lateral portion of the cut and confining the incision to a narrow arc about 2 5 cm wide passing back on the inner aspect of the lobe to a point directly beneath the anter horn of the ventricle at a depth of 5 5–6 0 cm from t frontal pole (fig 1) This modification was introdu to produce further evidence of the importance of t ventromesial fibres within the frontal lobe and to av damage to the hippocampal relays in the lateral portio of the lobe

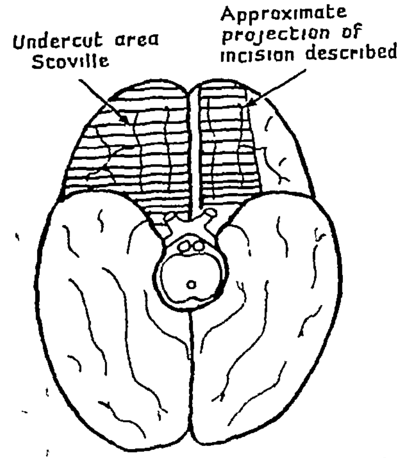

Fig 1—Approximate site and extent of incision in *Scoville's (1949)* undercutting operation and com [illegible] those of incision used in present

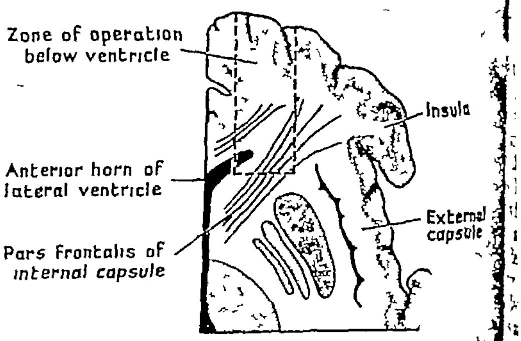
Electrocoagulation within the dorsomedial nucleus the thalamus (Spiegel et al 1947) produced bene effects chiefly in the emotional sphere These re are by no means solely attributable to the connect between the dorsomedial nucleus and the frontal pr jection areas (probably hypothalamic connections involved as well), but they do indicate that any signific fibres concerned in emotion and passing to the orb cortex must arise from the inner and lower area of lobe and hence could be divided close to their origin that point

Le Gros Clark (1948), discussing the afferent path from the thalamus, states that projection is well def between certain groups of cells in the dorsomedial nucl and the frontal cortex, fibres proceeding to cortical ar 8–12 approximately in order from the caudolateral part of t dorsomedial nucleus to the anteromedial part of the cort

Meyer et al (1947) concluded that it is the pars ma cellularis of the nucleus that projects on to areas 11 and in the orbital frontal cortex All the fibres projected to t orbital cortex spread thereto from the posteromedial asp of the lobe, and it is this area that has to be cut at the of concentration of the fibres below the pars frontalis o internal capsule rather than the outlying parts of the w matter towards the inferior frontal convolution (fig 2).



Zone of operation below ventricle
Insula
Anterior horn of lateral ventricle
External capsule
Pars frontalis of internal capsule

Fig 2—Transverse section through right frontal lobe seen from Interrupted line shows zone of operation lying at deeper le ventricle.

Lesions in the lateral aspect of the inferior surface o frontal lobes may *interrupt fibres passing* to the tem pole and hippocampus Efferent association tracts arise area 47 of the frontal lobe (area orbitalis agranularis) w running as the uncinate fasciculus, pass lateral to the ext capsule and radiate to area 38 in the pole of the tem lobe Degeneration has been observed near to or in this fasc by Meyer et al (1947) in post-leucotomy specimens Th fibres form part of a hippocampal circuit involving hi campus, fornix, hypothalamus, thalamus, orbital co uncinate fasciculus, temporal pole, temporo ammonic tr hippocampus, less well recognised than the well known cir hippocampus, fornix, mamillary body, thalamus, gyrus ci hippocampus Positive evidence on the function of th circuits is lacking

It has been suggested that neuronal activity could maintained in a steady state between these circuits long periods, forming a reservoir or background for emot expression Certainly bilateral disturbance of these cir seems to be undesirable

Klüver and Bucy (1939) reported changes in emoti behaviour in monkeys after excision of the temporal lo Hypersexuality has been observed after bilateral dam these circuits Serious results have followed ablation of posterior orbital regions in monkeys (Ward and McCu 1947) with loss of social conscience

Hence, although it has been suggested that tion of the uncinate fasciculus is more importa refrontal leu otomy than sec ion of the thal mocortical fibres, xcept where the im is relief of sceral pain, we mained uncon inced of the dvisability of this ep and decided eliberately to void these lateral d posterior spects of the lobe d so to avoid e possibility of troducing unde able character hanges which ave sometimes en observed in e case of pene ating wounds in at area of the rain

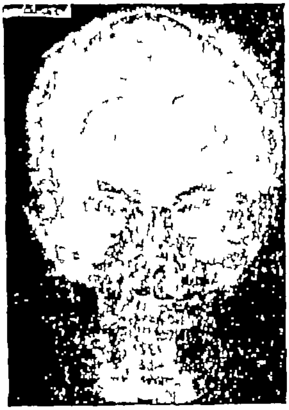


Fig 3—Position of trephine circles for orbital leucotomy

Operation

(G C K)

A transverse scalp incision concealed within the hair e is used the anterior flap being reflected forwards to pose the frontal bones as far down as the level of e orbital margins. A flap of pericranium corre ponding to the exposed area is similarly reflected for ards after mobilisation of the fascia from the line of the mporal crest on each side thus exposing the frontal nes Bilateral trephined circles 3 75 cm in diameter e now fashioned at a point above the level of the frontal nuses and extending to within 1 cm of the midline on ch side (fig 3) The bone-dust thus formed is collected r later use The exposed dura is incised transversely the lower third of the exposed area (fig 4) and stay tures are inserted The frontal pole is raised from the or of the anterior fossa to determine the level of the henoid clinoid process and a transverse incision 2 5 cm. de is made in the cortex hæmostasis is secured and e incision is deepened to the white matter Spatula rceps are inserted into the cortical incision and the hite matter is gradually divided with a fine suction be at the junction of grey and white matter above the bital plate on each side the incision being kept parallel the orbital roof as far back as the level of the tip of e ventricle the spatula blades being used as retractors. ould the tip of the ventricle appear in the line of the cision it is raised with the upper blade of the spatula, d the incision is deepened to a total depth of 5 5–6 0 m beneath the ventricular tip at which level it is dened transversely to 3 0–3 5 cm The incision is actically bloodless, but occasionally bleeding points are seen towards the inner aspect of the incision near the grey matter the bleeding is easily arrested by pressure or by electrocoagulation The dura is now closed with silk sutures and the bone discs are replaced and moulded into position with a paste made from the bone dust The pericranium is brought back into position over the bone discs to conceal any minor surface irregularity, and the wound is sutured in layers

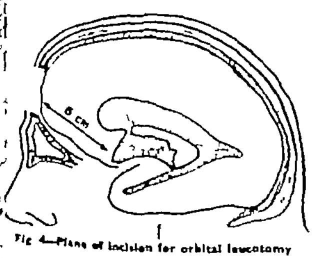

Fig 4—Plane of incision for orbital leucotomy

The postoperative course is smoother than that of a patient who has undergone major leucotomy Incontinence is hardly ever observed There is always a period of drowsiness for the first twenty four hours, and occasionally confusion for the first two or three days, but most patients are fully oriented on the day following operation Within four or five days they can be allowed out of bed, by which time the relief of tension is already apparent The mortality of this operation is obviously low so far more than 75 consecutive operations have been performed without any death

Psychiatric Survey

(R F T)

The survey included : (1) cases seen by me only after operation, and (2) cases seen before and after operation

1 Previous records were studied in detail and compared with the patients present state Since usually no formal or comparable assessment had been made by the psychiatrist who originally referred them it was not easy to be sure that comparisons were reliable ; but, to get as much uniformity as possible the tables of symptoms prepared (see below) were sent back to all these psychiatrists for their comments. In most cases, but not all the psychiatrists had seen their own patients again after operation.

2 These patients were seen immediately before the operation, soon after it and some weeks after it The changes were naturally easier to assess but here also the psychiatrists who had originally referred the patients were asked to comment on the opinions formed Among these patients were 12 Poles who were reviewed in the same way by Dr G Braun of Mabledon Park Owing to language difficulties it was impossible for me to make any adequate assessment in these cases but the criteria had been agreed with Dr Braun

TABLE I—EFFECT OF OPERATION ON SYMPTOMS

Symptom	No of patients with symptoms before operation	Results after operation			
		Much better	Better	Unchanged	Worse
Depression	3[illegible]	[illegible]	8	2	
Anxiety	37	19	11	3	1
Severe insomnia	8	4	4		
Headache	8	[illegible]	5	1	
"Blackouts"	2	2			
Gross lack of confidence	1[illegible]	[illegible]	8		
Lack of interest	18	8	9	1	
Obsessions	13	5	7	[illegible]	
Phobias	4	2	1	1	
Impaired memory	7	[illegible]			5
Impaired concentration	8	1	4		3
Loss of weight	7	7			
Ideas of reference	6	[illegible]	1	[illegible]	

The general results were classified as follows :

A	Markedly improved	23	
B	Some improvement	21	(of whom some are apparently still improving)
C	Unchanged	7	(of whom 3 had shown temporary improvement)
D	Somewhat worse	0	
E	Markedly worse	1	

The various symptoms recorded before operation are listed in table I together with the change after the operation

Besides these symptoms certain others were recorded before operation : rosacea (1), cleared menorrhagia (1) improved ; frigidity (3) improved in 2, but persisted in 1 hysteria (3) persisted ; palpitations (2) persisted and pruritus (2) cleared up

Table I shows that a great improvement was obtained as regards depression, anxiety and loss of weight many patients' interest in their surroundings was restored, and their confidence re established, and, although most of the patients expressed themselves as having some way to go yet, they had also some confidence that they would go this way The effects on failure of concentration and of memory were less good, and these symptoms were in several cases made worse This does not refer to the immediate postoperative period of a week or two, when some impairment of concentration and memory was expected (but passed), but to several months later Nevertheless these symptoms did not appear to cause any great anxiety in the patient No deterioration in personality was evident to me or to any referring psychiatrist in any of those in category A, B, or C

RELATION OF PROGNOSIS TO VARIOUS FACTORS

Previous Personality —Table II shows the cases grouped into various personality types and separated according to their grade of improvement The only conclusion which it seems legitimate to draw here is that hysterical personalities, like hysterical symptoms, offer less ground for hope

TABLE II—RELATION OF PERSONALITY TO PROGRESS

Type	No of cases	Category			
		A	B	C	E
Dependent	14	8	5	1	0
Cycloid	4	4	0	0	0
Obsessional	11	2	6	3	0
Hysterical	5	1	2	2	0
Schizoid	13	6	5	1	1
Psychopathic personality	1	0	1	0	0
Not psychopathic	4	2	2	0	0

Ætiology and Diagnosis —The nature and severity of the psychological factors which had precipitated the illness were investigated but the onset was so long ago that the history given cannot be very reliable In most cases, however, some emotional stress had either caused or precipitated a breakdown Classification being a matter on which psychiatrists notoriously disagree, the symptoms listed in table II and the diagnoses listed in table III may be regarded here with some reserve The 52 cases had, however, been labelled, under the existing nomenclature, and these have been tabulated against their progress It was clear that many cases showed a combination of anxiety with depression, or with obsessional features as table I shows

TABLE III—RELATION OF DIAGNOSIS TO PROGRESS

Diagnosis	Category			
	A	B	C	E
Reactive depression	5	5		
Endogenous depression	2			
Anxiety state	8	2	1	
Obsessional state	2	6	3	
Hysteria	1	2	2	
Schizophrenic state	5	5	1	1
Psychopathic personality		1		

Previous Treatment —These patients had mostly been selected, as noted above, because they had not responded permanently to treatment, but some had previously made temporary progress under electroconvulsion therapy (E C T), and it may be of interest to record the relationship here (table IV), for it is sometimes held that temporary relief from E C T is an indication for operation It seems fair to conclude that the response to E C T gives no indication of what the response to orbital leucotomy is likely to be

Length of History —So far as the records could be obtained, the grades of recovery were grouped against the d[illegible] of the illness (table V) Of the category C patients 2 were hysterics, this is at least as likely a rea as the length of history for their lack of improvem Though it appears that marked improvement is m likely in shorter cases, some improvement may expected from even the longest

TABLE IV—RELATION OF PREVIOUS E C T TO PROGRESS

—	Category			
	A	B	C	E
Previous benefit from E C T	8	7	1	1
No previous benefit from E C T	8	9	3	
Not previously treated with E C T	7	5	3	

Age —The correlation between age and progre given in table VI and does not seem to be significant

NEED FOR SUBSEQUENT PSYCHOTHERAPY

Some of the patients improved so much as to need further treatment, others, notably in categories B C, made less or temporary improvement and appeared benefit from psychotherapy where it was available, was notable, however, that some patients relapsed wh treatment was lacking (for reasons which reflected discredit on anyone), and this point should always considered by the psychiatrist when the patients retu to his care after discharge from hospital.

MAINTENANCE OF IMPROVEMENT

The patients were necessarily seen at different peri after their operation, and observations made on th rate of progress and its maintenance, or of relapse, can readily be analysed The following facts may, how be of interest

TABLE V—RELATION OF DURATION OF ILLNESS TO PROG

Duration (years)	Category			
	A	B	C	E
Up to 5	13	7	2	1
5–10	7	6	1	0
More than 10	1	8	4	0

(1) Some improvement was recorded in most pat within three days after the operation, but 1 patient di improve until seven months afterwards

(2) This improvement went on steadily for several w in most patients, and for months in some

(3) Several patients benefited from postoperative psych therapy whereas previously they had been inaccessible

(4) Nearly all those seen more than a year after operation had remained well since the end of that year

(5) Several patients graded as C (unchanged) had impro but subsequently relapsed

Illustrative Cases

Case 1 —(Reported by Dr JOSHUA BIERER)

A woman, aged 42, when first seen in 1950, complained depression, inability to travel, constant fatigue, dysp palpitations on effort, pains in various parts of the bo gastric disturbances, loss of appetite and weight, constipat insomnia, suicidal thoughts, and anxiety about illnesses as tuberculosis and insanity She seemed to be under g *emotional strain* She answered questions readily appeared to have difficulty over her memory and conce

TABLE VI—RELATION OF AGE TO PROGRESS

Age (years)	Category			
	A	B	C	E
20–30	5	3		
30–40	3	7	3	
40–50	4	5	2	1
50–60	8	4		
Over 60	3	2	2	

on. There were however no signs of hallucination, elusions, or feelings of unreality or depersonalisation

Past History —She had nearly died of pneumonia at the e of 9 and had had a duodenal ulcer while still at school. er appendix was removed at 20

Family History —Her father died at 55 of cerebral hæmor ge, when the patient was aged 17 but the mother lived til 1952 Mother was a very possessive dictatorial woman brother a year older than the patient, to whom she was atly attached was killed in a motor accident before her arriage

Childhood.—She had always been shy timid and reserved t quite normal apart from that. She was so shy that she ed to hide the fact that she was using the lavatory Felt wful' in her first school but felt happier when she changed r school at the age of 15

Sexual History —Menstruation started at the age of 17 xual relations with her husband caused pain and horror ding to frigidity Infrequent throughout marriage, and most ceased after birth of second child

Clinical Assessment —This patient looked younger than her e; her periods started late and her mother suppressed all velopment towards independence. The patient sought to d her independence in her married life but was too immature take any responsibility She expected pleasant feelings, fection, love, and security but instead she experienced orror and insecurity her husband being financially unreliable Having been used to complete dependence and having pected freedom from what she experienced as slavery she lt cornered. This caused such tension most of the time that en the security of nursing home specialists, and large doses f barbiturates did not bring her any relief Electroplexy d prolonged narcosis, like any form of psychotherapy ought her only a very temporary relief Life to her her mily and her doctors became unbearable

Progress —She postponed the operation twice because lations advised her against it in the end she agreed, and bital leucotomy was performed in May, 1951 She was sent r six weeks convalescence; she hated the place she was nt to the food, and the company She returned to work in r home rather too soon, according to her own statement

Effects —This emotionally and otherwise immature patient ho showed marked depressive hysterical and hypochondriacal symptoms of long standing who underwent and used others unbearable suffering was completely relieved y the operation and enabled to live a normal life again is was achieved with so little personality change that it d not interfere with her life Two years after the operation e described her state as a wonderful feeling' She had no mplaints, except sometimes slight nervous depression. All r tension has gone she can run her house and travel any here (which she could not do before) She enjoys going to the atre though she does not get the same thrill out of it

Case 2 —(Reported by Dr G BRAM)

A woman, aged 40 was admitted to Mabledon Park Hospital n June 27 1951 with delusional ideas of persecution pression and emotional instability

History —Apparently she was in good health until August, 44 when she was wounded by a shell splinter in the right rietal occipital region She was unconscious for several urs. For four months after being wounded she had left d paresis, and later she developed pain in the left shoulder d arm which did not respond to any analgesics.

Course of Illness.—On admission in 1951 she was apathetic d depressed and expressed delusional ideas of persecution; he said that the pain in her left shoulder and arm was caused y some electric currents used against her by unknown eople Three weeks after admission she refused to eat nd had to be artificially fed She had twelve electroconvul ons with very good response She became symptom free nd the pain in the left shoulder and arm completely subsided. he remained well for five months and then relapsed displaying he same symptoms as before A further course of E C T was iven but without any improvement

Orbital leucotomy was done in October 1952

Effects —The patient made remarkable progress and was ischarged in full remission four months later (the pain in he arm was no longer present) When she was readmitted for few days in September 1953 for review it was found that he had fully maintained her remission She can look after erself and do part time work The pain in her left arm had ever returned.

Case 3 —(Reported by Dr M WATSON and R F T)

A woman was first seen in 1952, at the age of 55 She had had depression since June 1949 fluctuating in intensity It had improved somewhat with E C T (but this produced so much panic that it was stopped) and with œstrogens and dexamphetamine but she had always soon relapsed. She had a demanding and sick husband and a daughter with disseminated sclerosis One suicidal attempt Her depression was associated with guilt indecision and feelings of emptiness in her head some paranoid ideas; short occasional hypomanic phases with gross extravagance

Past History —Subtotal hysterectomy at the age of 42. No menopausal symptoms Left mastectomy at 43 for carcinoma.

Family History and Childhood —Apparently happy relationships with no relevant incidents. Husband a war pensioner now unreasonable and doing no work Five daughters.

Orbital leucotomy in March, 1952

Effects —Much improved twenty five days after operation and steady progress until seen eighteen months later except for two interludes—a gross obstructive jaundice in July 1952 and a short phase of laziness and aggressiveness in December, 1952 The jaundice was completely painless and a secondary carcinoma was suspected but it cleared up in three weeks and was apparently an infective hepatitis In November 1953 she had no complaints, being cheerful and placid, but not unduly so She was quite rational, coöperative, and capable of coping with the domestic stress which still persisted She regarded the change in herself as wonderful

Conclusions

The criteria used to select these patients had not been carefully defined beforehand, but clearly most of them had severe anxiety or severe depression They had long records of illness and misery (misery which affected their families too) *no previous psychotherapy had been of* avail E.C T had given little relief, and surgery was their last hope In these circumstances a high percentage of success would scarcely be looked for

This being so the success of the operation seems remarkable 23 out of 52 were markedly better, 21 somewhat better and only 7 unchanged Only 1 was worse in general, and though a few had greater difficulty in concentration or memory even these regarded themselves as better and happier A deterioration of personality was recorded in only 1 case

Though no sweeping conclusions can be drawn in an interim report on so small a series, these results suggest that orbital leucotomy should be seriously considered in long-standing severe anxiety states and depressions which do not respond to psychotherapy

It is not yet possible to say which patients will benefit most. Previous response to E C T offers no guide to prognosis nor does age The results seem more hopeful if the duration has been less, as might be expected Cases with hysterical symptoms do not seem to be suitable for the operation

All cases should be reviewed by their original psychiatrist after the operation Some patients need further psychotherapy and will benefit from it even if they did not before

We are much indebted to our neurosurgical colleague Mr G Northcroft for preparing the accompanying diagrams We would like to express our gratitude to all the psychiatrists in this region who recommended patients, supplied information and checked the assessment made later; and in particular we wish to thank Dr Bierer and Dr Bram for more detailed assessment and for permission to publish in detail the findings in cases 1 and 2

UNDERCUTTING OF ORBITAL CORTEX IN CHRONIC NEUROTIC AND PSYCHOTIC TENSION STATES

R STROM-OLSEN
M D Wales, B Sc , D P M
PHYSICIAN SUPERINTENDENT

D W C NORTHFIELD
M S Lond , F R C S
NEUROSURGEON

RUNWELL HOSPITAL, WICKFORD, ESSEX

THE risk of personality defects has deterred many from applying leucotomy in chronic neurotic and other tension states (Strom-Olsen 1946) The patient with a well-preserved personality is likely to show greater loss than one with a simple and shallow personality (Ström-Olsen and Tow 1949) , and, though standard leucotomy can be justified for a chronic disturbed psychotic who usually shows much deterioration, it is in our opinion inadvisable for the person with an intractable neurosis A different operation was therefore required for cases of chronic anxiety, obsessional neurosis, and hypochondriasis, and for some cases of paranoid psychosis and chronic depression which do not respond to electroconvulsion therapy (E C T) or other treatment

TABLE I—CATEGORY A

Case no	Diagnosis	Duration of illness before operation (yr)	Length of follow up after operation	Result
1	Chronic anxiety state	5	4 yr	Recovered
2	Chronic hypochondriasis	15	$3^{1}/_{4}$ yr	Recovered
3	Chronic anxiety state	8	$2^{3}/_{4}$ yr	Improved
4	Chronic hypochondriasis	11	$2^{3}/_{4}$ yr	Improved
5	*Psychopathic* personality and drug addiction	8	$2^{1}/_{2}$ yr	Improved
6	Paranoid schizophrenia	5	2 yr	Recovered
7	Chronic hypochondriasis	20	2 yr	Improved
8	Chronic anxiety state	4	2 yr	Recovered
9	Chronic endogenous depression	$3^{1}/_{2}$	$1^{3}/_{4}$ yr	Recovered
10	Paraphrenia	5	$1^{3}/_{4}$ yr	Improved
11	Chronic anxiety state and depersonalisation	$3^{1}/_{2}$	1 yr	Recovered
12	Chronic melancholia	10	$5^{1}/_{2}$ mos	Not improved, died
13	Chronic depression	3	5 mos	Recovered

The method of selective cortical undercutting devised by Scoville (1949) was adopted at Runwell Hospital in January, 1950 Mr Geoffrey Knight, then neurosurgeon to the hospital, was the first to perform the operation in this country, and he operated on the first 9 cases, which are not included in the present series

In view of the experience of Scoville (1949) and Rylander (1951) the selective undercutting operation has been restricted to the orbital cortex We have no experience of undercutting either the cingulate area or the superior convexity of the frontal lobe

Material

The series consists of 27 patients operated on January, 1951 They fall into two categories (and II)

A. Patients with well preserved personalities who suffe from long standing tension states, depression, or other e tional distress which had completely incapacitated th Each had received other forms of treatment without perma beneficial results

B Chronic disturbed psychotics, usually schizophre who already showed considerable deterioration and in w the aim was a nursing improvement rather than a cure

Serious postoperative defects would be discerned rea in the first group, but less readily in the second

Of the 27 patients 8 were men and 19 women 3 m and 10 women in category A, and 5 men and 9 wome category B Their ages ranged from 23 to 61 years, being between 23 and 40, and 10 between 41 and 61.

Operation

The operations have been carried out under gen anæsthesia and along the lines described by Sco (1949) and by Tow and Lewin (1953)

It has not been found necessary to use a trephine la than $1^{1}/_{4}$ in in diameter, and this size is much easier to manip late than a larger one The *trephine is placed so as to br* the edge of the opening in the skull as close as possible to th orbital roof, and about 1 cm either side of the middle line. I some cases the frontal sinus has been traversed , when th has happened, the mucosa of the sinus has been tur inwards towards the nasal duct, and the mouth of the cavit lightly packed immediately with 'Gelfoam' liberally p dered with penicillin and sulphathiazole , any separ portion of mucosa attached to the disc of bone has b entirely removed, and the overhanging lip of bone (for the detached posterior wall of the sinus) has been nib from the disc In such cases prophylactic penicillin is g for five days after the operation, and no complication followed the opening of the frontal sinus

During the closure of the wound the discs are sutur place, and the crevice which surrounds the replaced dis filled with bone dust , this prevents the unsightly defor which may become apparent some months after the opera when the scar tissue contracts and reveals a circular groo the site of each trephination

Provided the trephine openings are low in the frontal the tip of the frontal pole will be exposed after incisi dura mater, and the lightest degree of retraction will one to elevate the frontal pole so as to bring the optic n into view at the point where it enters the optic foramen, on each side to measure its depth from the anterior surfa the pole This is the depth to which the "cut " should

TABLE II—CATEGORY B

Case no	Diagnosis	Duration of illness before operation (yr)	Length of follow up after operation	Result
14	Paranoid schizophrenia	6	$2^{3}/_{4}$ yr	Improved
15	Paranoid schizophrenia	$7^{1}/_{2}$	$2^{3}/_{4}$ yr	Improved
16	Paranoid schizophrenia	9	$3^{3}/_{4}$ yr	Improved
17	Chronic schizophrenia	10	$2^{1}/_{2}$ yr	Not improved, died of intercurrent disease
18	Paranoid schizophrenia	$3^{1}/_{2}$	$2^{3}/_{4}$ yr	Not improved, subsequently had standard leucotomy
19	Paranoid schizophrenia	36	$2^{3}/_{4}$ yr	Improved
20	Catatonic schizophrenia	17	$2^{3}/_{4}$ yr	Not improved
21	Paranoid schizophrenia	$4^{1}/_{2}$	$2^{1}/_{2}$ yr	Improved
22	Hebephrenic schizophrenia	$3^{1}/_{2}$	$2^{1}/_{2}$ yr	Not improved
23	Chronic paraphrenia	$8^{1}/_{2}$	$2^{1}/_{4}$ yr	Improved
24	Schizophrenia	7	$1^{3}/_{4}$ yr	Recovered
25	Catatonic schizophrenia	6	$1^{3}/_{4}$ yr	Improved slightly
26	Catatonic schizophrenia	4	$1^{1}/_{2}$ yr	Unchanged
27	Paranoid schizophrenia	15	10 mos	Improved

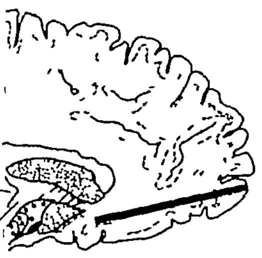
ade and should not be transgressed If necessary the [illegible] arachnoid can be broken and cerebrospinal fluid moved by suction to gain extra room. The brain is now lowed to resume its normal position and a suitable site on e frontal pole is chosen for the cortical incision which runs ansversely for the full diameter of the opening in the bone d approximately parallel to the roof of the orbit The ecise position of the incision depends on that of veins d on the cortical pattern large veins should be avoided if sible, and an incision through the summit of a gyrus avoids all arteries hidden in sulci The obliteration of a large vein y give rise to local congestion, making the operation more ficult. The cut is now made into the brain in a plane rallel to the orbital surface of the frontal lobe and about m. under it. The correct direction is repeatedly verified by moving the spatula or other instrument used for the dissec n, and reorientating oneself in relation to the roof of the bit. As the cut is deepened a narrow retractor is held so as maintain the orbital surface of the brain against the orbit hen the required depth has been reached (centimetre kings on the retractor are a great help) the cut is gradually tended medially until one estimates that the middle line s been nearly reached, and then laterally until increased sistance indicates that the lateral cranial wall is being proached.

Hæmorrhage in the depths of the cavity is controlled by e common neurosurgical methods, which are used until gentle irrigation reveals that hæmostasis is satisfactory The under surface of the frontal lobe is now re-examined to make sure that no unsuspected hæmorrhage has taken place on the outside of the brain the dura mater is approximated with silk and covered with a piece of gelfoam



1—Sagittal view of brain 1 cm. lateral to line showing usual position of lesion in orbital undercutting: IC, internal capsule; thalamus. (Tracing from myelin-stained ction.)

It is essential that anæsthesia should be induced and maintained expertly so as to avoid all cerebral congestion due to ory obstruction, cyanosis or retention of carbon dioxide he brain bulges when the dura mater is opened one should it for this to subside, checking for possible defects in the ministration of the anæsthetic in these circumstances it is er to postpone operation than to attempt undercutting

The position of the head is important; if it is moderately ended the weight of the brain causes the frontal lobe to fall ay slightly from the roofs of the orbits, thus reducing the ree of retraction necessary

Orbital undercutting is a delicate operation which annot be performed hurriedly It demands a much gher standard of technical skill and attention to detail han does leucotomy and should never be undertaken ithout the full panoply of neurosurgical assistance and paratus Inspection of the specimen (figs 1–3) has mphasised the narrowness of the margin between the sterior part of the orbital cortex and the inferior pect of the anterior extremity of the caudate nucleus At this depth deviation from the correct plane must learly be very easy and damage in either direction or at oo great a depth may lead to fatal consequences.

Results

Category A.—Of the 13 patients in this category 7 ave recovered 5 have improved and 1 has shown no hange Of the 12 recovered or improved 9 have been ischarged from hospital 7 of them are living normally t home and working for the first time in many years; he remaining 2 are free from symptoms and are steadily mproving but have not yet fully adapted to the stresses of life outside hospital These patients have experienced marked subjective relief of their emotional tension, distress or aggressive tendencies, according to the diagnosis Experience has shown that improvement in social adaptation may continue up to two years after discharge

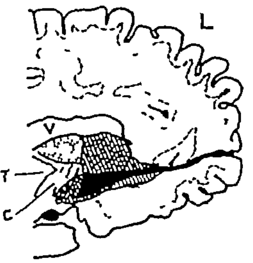


Fig. 2—Comparable (same scale) sagittal view of brain of case 12: IC internal capsule; T thalamus; V ventricle; black complete loss of tissue; hatched partial loss of tissue. (Tracing of fixed brain.)

Category B.—As was to be expected the results in this category are less favourable Only 1 has shown a social recovery but improvement has been evident in 8 of whom 4 have been discharged to their homes. This improvement has been greatest in patients who suffered distress because of hallucinations or displayed impulsive and violent behaviour However, our experience leads us to believe that undercutting of the orbital cortex is insufficient for the more severe schizophrenics because one such patient had afterwards to undergo a standard leucotomy Of the 4 chronic psychotics who were discharged 1 schizophrenic made a social recovery and has started working for the first time for many years, 2 have been relieved of their psychotic symptoms (1 is working full time and supporting her family, and the other lives a fairly normal existence and does some housework) the 4th patient, a young schizophrenic was discharged against advice and has not shown any improvement.

In both categories those patients remaining in hospital who were classified as improving have had considerable relief They are now nursed in better wards and can enjoy more freedom within the hospital

Postoperative Complications

There were no cases of clinically recognisable cerebral hæmorrhage following the operation Patient 5 in category A had epileptiform fits on the second day after the undercutting but has had none since Patients 2 and 8 in category A developed complete loss of the sense of smell, presumably through injury of the olfactory bulb tract or cortex. Patient 20 in category B had hyperpyrexia and coma for forty-eight hours but made an uneventful recovery

Incontinence of urine so distressing in many post leucotomy cases, is occasionally met with during the first

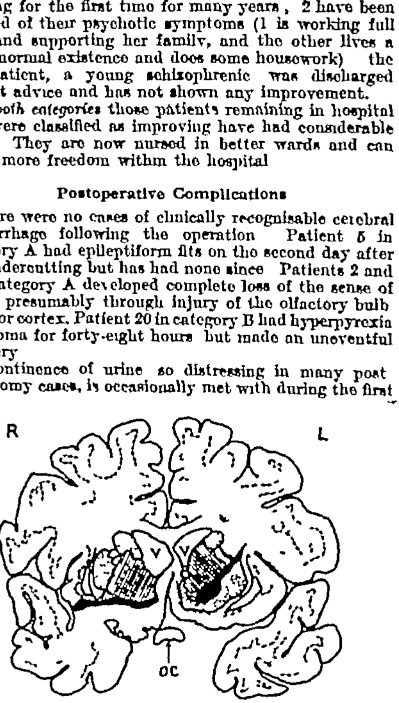

Fig 3—Coronal view of brain of case 12 at level of optic chiasma: OC optic chiasma; V ventricle; black, complete loss of tissue; hatched partial loss of tissue. (Tracing of fixed brain.)

week or two following orbital undercutting but has never persisted Except in patient 12 in category A, there were no serious or permanent postoperative complications This is in marked contrast to the standard leucotomy

Postoperative Personality Changes

The 27 patients have been thoroughly investigated for postoperative personality change, and the 24 who proved coöperative have also undergone psychometric tests by Dr Graham Foulds The 13 discharged patients have been followed up in detail at regular intervals, and not only have the relatives and the patients been interviewed, but in all cases the homes have been visited by one of our psychiatric social workers and sometimes also by one of us Special importance was attached to statements by relatives, not only on the improvement they noticed in the mental picture but also particularly on the development of undesirable symptoms In this respect the difference between the present patients and those who have undergone standard leucotomy is very striking Except patient 12, none of those in category A has shown any serious personality defect The same is true of the chronic psychotic patients, category B, though here it became less easy to distinguish between deterioration of the personality due to the psychosis and deterioration due to the operation Compared with changes seen after standard (or medial) leucotomy, there have certainly been no serious or unpleasant psychological or behavioural sequelæ There is, in our opinion, a quantitative rather than a qualitative difference There is some loss of spontaneity, which tends, however, to lessen as the months go by Some patients complain of an abnormal tiredness for the first few months Although abnormal emotional tension is eased, there is little blunting of affect—certainly never to the point of apathy For the first few weeks there is a tendency to emotional facility, with at times outbursts of laughter for little apparent reason, but this symptom has always subsided In the social sphere the recovered patients are able to work efficiently and enjoy their pleasures, contrasting vividly with post-leucotomy patients 2 of the chronic psychotic patients appeared to develop increased sexual drive However, in one of these cases there was evidence of eroticism before the undercutting It may well be that inhibition diminished

24 patients were tested psychologically four weeks after operation and 12 were tested again six to twelve months after operation The tests included Mill Hill vocabulary scale, progressive matrices, porteus mazes, thematic apperception test, Rorschach test, and Wechsler Bellevue test The outstanding features of the results so far obtained is their constancy and the absence of any sign of intellectual deterioration On the credit side are improvements in appetite, sleep, and sociability, thus patient 5 in category A, who had for years been habituated to amylobarbitone, could take little food, and was in danger of dying from starvation, quickly regained her appetite, put on weight, and could do without night sedation

Complications due to too Posterior Cut

Case 12 in category A—that of a woman of 54, with ten years' melancholia—demonstrates the danger of a lesion extending too posteriorly

After her undercutting operation in May, 1954, she was extremely drowsy for an abnormally long time She had to be fed and was incontinent She showed complete apathy, had a mask like expression, and developed signs of bilateral pyramidal damage and parkinsonism, she could not walk or stand The blood protein picture showed an absolute increase of globulin (total serum protein 6 3 g per 100 ml, albumin 2 2 g, globulin 4 1 g, albumin/globulin ratio 0 54) Within the globulin fraction the α_1 component showed a significant increase over the normal values The blood levels of urea, sodium potassium, calcium, magnesium, and chlorides were all normal, as was the CO_2 combining power The most striking feature, however, was intractable trophic ulcers both shoulders, the outer edges of both feet, the sacrum buttocks, the trochanters, the big toe joints, both heels, left external malleolus, the left fifth toe, and the left Some muscles and tendons had been eroded right thro and even the great trochanter had been eroded These ul were severely infected

In spite of intensive treatment the patient gradually deteriorated, lost weight, and eventually died, five and a h months after operation, from pneumonia, septic absorp and cachexia At necropsy (Dr J A N Corsellis) the bra weighed 930 g, on both sides the surgical lesion had extend through the head of the caudate nucleus, the putamen the related segment of the internal capsule (solid black in fig 2 and 3) The area of partial damage however (as shown b hatching) appeared to be secondary and due to interference with the blood supply

In this case, it will be noted, the brain was abnormally small, and this may well explain why the section w carried too far back from the frontal pole Similar ca of severe trophic disturbances have been described following leucotomy where the cut has been made mo posteriorly than normally (McLardy 1950)

Illustrative Case-reports

Case 1 —A man, aged 34, was admitted to Runwell Hospi because of anxiety with nervous vomiting, which began dur convalescence from pulmonary tuberculosis in Septemb 1950, and was causing physical deterioration He had alw been a nervous and sensitive person and had had bronchi asthma since the age of 9 In 1946 he was discovered to h pulmonary tuberculosis and received sanatorium treatm until October, 1949 Severe anxiety symptoms began when h began to get up from a course of rest in bed. He felt afraid leaving his bed, had a sensation of "nervous tension in t solar plexus," and would vomit, at first when anyth untoward happened, and then after meals regularly two three times a day He was preoccupied with the idea that h tuberculosis would break out again at any time, and att of asthma, which had been rare while he was in the sanator began to recur frequently

When admitted he had already lost 21 lb Psychother and sedation failed to produce any improvement Sh after admission the tuberculosis was found to be active more, and he was treated by chemotherapy He bec increasingly anxious and vomited so much that it was im sible to continue giving him *p* aminosalicylic acid, and h dietary intake was quite inadequate It was decided th orbital undercutting, while his general condition rem good enough to permit the operation, was the only treat open, and the operation was performed under general an thesia in January, 1951

Progress After Operation —With continued chemother recovery from operation was uneventful After a week th patient appeared more calm, did not complain spontaneo of his fears, and took his diet well, though he denied improve ment when questioned There was a gradual over all improve ment in his anxiety symptoms during the following mont except for two transient re-exacerbations of fear and vomit eight and ten weeks after operation, which did not interf with the steady improvement in his pulmonary conditio Eighteen months after the operation he was ambulant, n longer afraid of exertion, optimistic about the future, a making plans for a return to normal life He was still slight anxious about meals, and feared a return of vomiting Unfor tunately a series of upper respiratory tract infections delaye his discharge from hospital for some months, but he continued to gain confidence and was fit for discharge twenty two mont after operation. There was no return of the vomiting, and h was eventually sent to a tuberculosis rehabilitation unit, wher he started work as a welfare officer, driving his car abou without any symptoms of fear or anxiety

Follow up —When seen nearly three years after the opera tion he had been disabled through an attack of asthma bu was now well and was going back to his job He admitted that he was vastly improved and could do his work as far a his chest condition would allow him He was cheerful and there was no evidence of tension His parents stated that th could not see any detrimental traits following the operatio

Case 2 —A woman, aged 59, who had had two previo admissions to Runwell Hospital, was admitted for the th me in November 1951 The history of her neurosis went back for at least fifteen years and she was almost completely incapacitated. She had depression anxiety and agitated hypochondriasis She was given various forms of treatment including E.C.T with no improvement She spent most of her time in bed and, when at home could barely help with any housework, at times having to crawl about on her hands and knees.

On admission she was tense agitated and hypochondriacal with severe insomnia severe pains in the abdomen and head weakness of the legs palpitations and pains in the chest She was preoccupied with her symptoms to the exclusion of anything else She swayed about, wringing her hands and moaning continually asking for sleeping-drugs to ease her The symptoms had gradually got worse during the three or four years before admission but were essentially the same as though rather less severe than when she was first seen at the outpatient clinic in 1937 Bilateral undercutting of the orbital cortex was performed on Dec 24 1951

Progress After Operation.—For the first four days she was somewhat drowsy and was unaware that she had had an operation. Ten days afterwards she was placid and cheerful, with no agitation. She no longer spoke in a whining voice and hand-wringing was absent She could smile and laugh and said she felt much better There was no incontinence but she was rather slow in eating her food During the following two months she steadily improved and in March, 1952, she was discharged symptom free

Follow-up —She has been visited in her home several times since and her son also has been interviewed When last seen three and a quarter years after operation she was doing all her cooking and housework. Whereas previously she never got up until 12 or 1 o clock, she was now up by 7 A.M She went out two or three times a week and had taken up her hobbies again. She said: "There is a vast improvement in me I can now sleep without drugs, I am not a bit depressed all those dreadful sensations are gone She read good books and had no difficulty in concentration Physically she was stronger and had put on some weight

Case 6.—A woman, aged 38 at the time of operation had had paranoid schizophrenia for four years, during which she had been admitted three times to hospital At first her illness was characterised predominantly by apathy withdrawal and inaccessibility She had auditory hallucinations and delusions of a persecutory nature—e g that she was always being watched by radio and television and that someone else came into the house to usurp her place whenever she went to bed or went out. She believed that her husband was unfaithful to her and she was frigid towards him and she lost interest in her children. She was disconnected in conversation and showed thought blockage Eighteen months before operation she began to be aggressive and attacked her husband and the nurses. She became increasingly violent and impulsive apparently in response to hallucinations. Orbital undercutting was performed there was excessive bleeding at operation, and generalised epileptiform convulsions came on that evening She was incontinent for six days but after this convalescence was smooth

Progress After Operation —A week after operation she was still extremely apathetic but was coöperative and denied having hallucinations. After a month she was showing more interest in her surroundings, attending occupational therapy helping with light duties on the ward and keeping herself presentable She remained cooperative and well conducted and conversed freely There was no tension and no evidence of hallucinations nor did she voice any delusions. She went home three months after operation and was discharged after a further five weeks. At home she took up her duties in the house and looked after her children, and relations with her husband became satisfactory

Follow up —Seen about twenty-one months after the operation she remained very well She was contented and there was no evidence of tension or hostility or of delusions or hallucinations; these had petered out Marital relations with her husband had become perfectly normal. She was now doing most of the housework cooking and cleaning though she did not often go shopping She had become affectionate towards her husband and children. She did not tend to lie in bed in the morning but made an early start with her housework. The husband remarked that the only thing he noticed wrong was that she could not plan things well sometimes showing lack of foresight but apart from that he regarded her as perfectly normal.

Case 8 —A woman aged 34 had had a chronic anxiety state with panic attacks for four years Depression and anxiety had been developing since early 1949 before which she had had a well integrated personality and held responsible executive posts She improved somewhat at first and left hospital in July 1950 only to be readmitted in April 1951, with an exacerbation of anxiety and panic attacks She was now extremely tense and trembly showing tachycardia and complaining of pains in the chest weakness of the legs and loss of energy and self-confidence In spite of sedation and psychotherapy she did not improve She had slight myxœdema following a thyroidectomy, but this was kept well under control with small doses of thyroid. For the next two years she continued in more or less the same condition. She was often lacrimose easily upset and complaining of constant fears No physical treatment improved her condition She was restless, irritable and at times excitable and she continually complained of tiredness She underwent an orbital undercutting operation in April 1953

Progress After Operation —Immediately afterwards she was completely relaxed and at ease There was no evidence of depression and the crying bouts ceased She was amnesic for the operation She continued to make good progress, and four months after the operation she was discharged and went to live with a friend who knew her very well.

Follow-up —She has been seen on numerous occasions, and her social recovery has been maintained for the past two years Unfortunately she has severe purulent sinusitis which gives rise to headaches and muzziness At times she is anxious about her health but this appears to be a normal reaction. Her friend is extremely pleased with the result The patient looks much better physically She can do her shopping though she cannot do her work. She still complains of tiredness and lethargy but she mixes much more socially with other people and remains quite free from neurotic symptoms.

Case 9 —A woman aged 50 began to have chronic melancholia at the menopause three and a half years before operation Her previous personality was over-conscientious and rather obsessional Five months after cessation of her periods she was admitted to the hospital under certificate after a suicidal attempt with aspirin She was depressed and expressed numerous delusions of guilt—e.g that she was contaminating all those around her and that she was the source of all the cancer tuberculosis, and blindness in the world. She had auditory hallucinations and heard people accusing her of sexual misdemeanour At this time she was experiencing menopausal vasomotor symptoms. Although she responded well to convulsion therapy she relapsed within a few months and after the third course of treatment the remission lasted only ten weeks. Recurrence of depression was accompanied by retardation: she lost all interest in life and in her relatives felt that all contact with other people was wicked and refused her food At the time of orbital undercutting she had been continually depressed for ten months

Progress After Operation —A week after operation she showed clear improvement. She was only mildly depressed showed affection for her relatives and took her diet with little persuasion Improvement continued and melancholic symptoms gradually faded out Two months later she was cheerful and active, eager to help with work on the ward and sociable and she liked to attend all the social functions in the hospital though she still occasionally expressed self accusatory delusions. She left hospital on trial and was discharged five months after operation.

Follow up —She has been seen regularly at home where she lives with her sister and as an outpatient during the year that has elapsed since her discharge and has remained quite well She shows no depression or delusions is active neat and tidy (still having a keen regard for cleanliness and orderliness) and feels capable of doing her share of household duties and shopping She likes to go out a good deal and enjoys radio and television though she finds her interest in reading somewhat diminished. Her sense of smell is absent since the operation. She looks considerably younger and smarter than before

Case 11 —A woman, aged 29 had had severe anxiety symptoms with depersonalisation for two and a half years before operation Her illness began suddenly after a minor bicycle accident in which she was not injured She was anxious and afraid to leave the house and to stay in the house by herself and she could not believe in the reality of [illegible] ment or in her own reality She could not do [illegible] and was continually preoccupied with her symptoms She was admitted to other hospitals on three occasions before her admission to Runwell Hospital and had received various courses of treatment, including E C T and insulin therapy, without relief from her symptoms Observation for nearly a year before operation showed her to be continually complaining of the symptoms and importuning for reassurance about her unreal feelings "Am I alive, or am I dead? Is it today? When will things look real?" She said she could not think of anything else or enjoy any activity There were periods of agitation when she was unable to sleep, and she took little interest in her appearance

Progress After Operation—After operation she was no longer agitated, slept without sedation, and was free from feelings of unreality, she kept herself well occupied with ward work and occupational therapy, and took full advantage of social facilities She conversed freely and easily, laughed, and enjoyed herself She was discharged six weeks after operation and at once took up her management of the home and her old interests

Follow up—She and her husband were seen separately three and a half months after discharge She had put on weight, previously having been thin and undernourished She looked considerably younger Her husband said there was a dramatic improvement There was no agitation or depression She was looking after her home very well and getting up early She no longer presented any symptoms of depersonalisation and had not once asked for reassurance She found that her housework was not quite enough and would like more to do She had normal initiative She enjoyed such entertainments as cinema, radio, and dancing, and there was no evidence of impairment of drive or concentration At times she complained of tiredness, but this in no way interfered with her activities She has now obtained employment and is working full time

Case 13—A dock labourer, aged 31, had depression with paranoid delusions for three and a half years before the operation Previously he had enjoyed excellent health except for an accident at the age of 30, when he fell 60 feet, fracturing his spine and wrist, without persisting disability At the onset of his mental symptoms he would return from work morose and disgruntled and would sit brooding for hours Shortly after this he expressed paranoid ideas about his work-fellows, became increasingly agitated, depressed, and sleepless, and believed that men were surrounding the house, talking about him, and trying to get in at him This culminated in his admission to hospital after attempting suicide by cutting his throat

On admission he was tense, depressed, and retarded, with little spontaneous activity, and showed a tremor of his hands and lips He said that his work mates had "put the pressure" on him, had called him a "wrong un" and a "copper's nark." He heard a voice in his head repeating "He is insane, he is insane" and other derogatory remarks He said he had been forced to protect himself and on one occasion had attacked a work-fellow with a knife He had also been drinking heavily for some months He was full of remorse for his wrong doings and felt that he was unworthy of his family

Response to E C T was good, and he left hospital and returned to work after eight weeks, but he soon began to drink again, and later became depressed and was readmitted, having been home for six months after a second suicidal attempt Further courses of E C T produced only temporary improvement, and he remained in hospital in a depressed and deluded state Orbital undercutting was performed three years after his original admission, and at this time he had been continually depressed for a year

Progress After Operation—After operation tension was still present at times, but he was not depressed. During the two postoperative months before his return home he gradually lost his tension, and was happy and friendly with the other patients whom he had previously believed were talking about him

Follow up—Four months after operation he remained well and entirely free from psychotic symptoms, depression, and tension and appeared placid and contented He looked after himself well spontaneously, occupied himself with jobs about the house, reading, and going for walks Immediately on discharge he was eager to start work again He was advised to take it easy for a while, but there is no doubt that he is now fit to do a full day's work

Discussion

Scoville (1949), who devised the first undercutting operations as opposed to topectomies and gyrectomies, suggested three sites for the operation according to the nature of the disorder (1) the superior convexity of the frontal cortex corresponding to Brodmann's areas 9 and 10; (2) the medial frontal cortex cingulate area, and (3) the orbital cortex areas 11 and 13 Scoville regarded the undercutting of the orbital cortex as the ideal operation for the relief of chronic neuroses and milder mood disturbances, because of the almost complete absence of personality changes Our best results are in just these conditions—i e, chronic anxiety states and chronic depressions—but some of the patients with a paranoid psychosis who had much tension or suspiciousness benefited greatly from the operation On the other hand, in severe psychotics the operation may be found insufficient quantitatively As mentioned above, case 5, in category B, had subsequently to undergo a standard leucotomy

In such an unpredictable field as neuro anatomy, especially in the present state of our knowledge, a discussion on correlation between clinical findings and operative lesions, examined post mortem, is not likely to be very profitable Much more material from recorded cases will have to be examined It may be of interest, however, to note that, according to Fulton (1951), the hypothalamus projects to the cerebral cortex by way of two main groups of thalamic nuclei, the anterior and the dorsomedial nuclei As regards the dorsomedial nucleus, the most medial portion is that which receives messages from the hypothalamus, and this projects to the orbital surface, especially the anterior part and the frontal pole (Le Gros Clark 1948, Le Gros Clark and Meyer 1950) The lateral part of the dorsomedial nucleus sends fibres to the convexity of the frontal lobe Neuro physiologists suggest that this tract provides an essential relay mechanism through which the activities of the hypothalamus can immediately influence those of the higher functional levels of the cerebral cortex Interruption of the pathway between the magnacellular portion of the dorsomedial nucleus and the orbital cortex may diminish to a very large extent the number of impulses influencing "consciousness," and in this way, it has been argued, provide relief from a state of tension

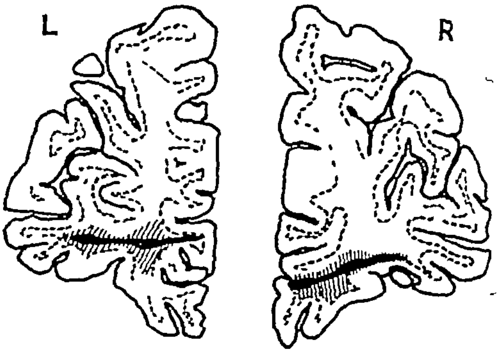

Fig 4—Coronal section 3 cm posterior to frontal pole (case 17): black, complete loss of tissue, hatched, partial loss of tissue (Traced from myelin-stained section)

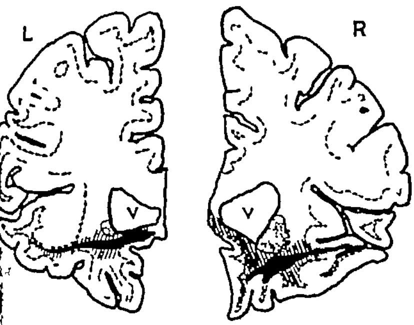
In this connection the following neuro anatomical observations are of importance Patient 17, in category B, a woman of 26 with long standing paranoid schizophrenia and much deterioration, who was operated on in October, 1951, died of intercurrent disease (carcinoma of the ovary) two and a half years later We are indebted to Dr Corsellis for the following report

"*At the frontal pole on both sides there* was a horizontal slit-shaped cavity 2 0 cm × 3 0 mm, which first penetrated the polar cortex and then opened out into the white matter deep to the orbital surface On both sides, at a coronal level 3 0 cm. behind the frontal pole (fig 4), the medial two-thirds of the orbital cortex had been undercut, although on the left



g 5—Coronal section 4 cm. posterior to frontal pole (case 17): V ventricle; black complete loss of tissue; hatched partial loss of tissue. (Tracing from myelin-stained section.)

e the lesion was slightly more dorsally placed The widest onal extent of the undercutting was at a level 4·0 cm from e pole (fig 5) when the entire width was affected Posterior this level the lesions rapidly narrowed and they died out ntral to the most anterior limits of the heads of the caudate clei—i.e., 5·0–5·5 cm. from the frontal pole (fig 6)

Histologically the cavities were encircled by a narrow e of demyelination always less than a few millimetres deep part from the entry wounds the frontal cortex was not preciably affected and the only other changes were ondary ones related to the primary lesions. These included ateral degeneration of a small segment of the internal psule and of the medial part of the dorsomedial nucleus of e thalamus.

Although this case, from a clinical point of view is a d example because the patient was already grossly teriorated when operated on the neuro anatomical anges are of great interest because they seem to confirm at at least part of the tracts carrying visceral impulses m the hypothalamus via the thalamus had been ered The results of a more detailed investigation of e brain by Dr Corsellis will appear elsewhere No hard l fast conclusion can of course, be drawn from this le specimen; but continued study along these lines specimens become available will further our progress ards a more definitive method of relieving mental order by operation

Summary

The results in 27 patients who have undergone bilateral dercutting of the orbital cortex are described

The patients were divided clinically into two groups: with well preserved personalities, of whom 7 were onic neurotics (category A) and 14 who were deteriorated psychotics (category B) In category A 9 patients were afterwards discharged, of whom 7 were regarded as recovered and 2 as improved In category B 4 patients were discharged, of whom 1 was a social recovery 2 were improved and 1 was not improved

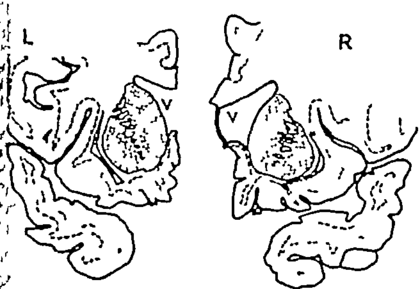
Of the remaining 3 in category A 2 improved in category B 5 did not improve and 1 of these subsequently underwent a standard leucotomy

There was no immediate postoperative death, but 1 patient with an abnormally small brain, in whom the cut had been carried too posteriorly died from extensive trophic ulceration five and a half months after operation

The *postoperative personality* changes have been negligible or very slight and have never reached the disturbing proportions seen after standard or medial leucotomy

The absence of serious personality defects and other complications after undercutting of the orbital cortex renders this operation preferable to standard leucotomy in chronic and apparently intractable neurosis or depression

This operation is also to be recommended in well preserved psychotics who exhibit tension and psychomotor unrest due to delusions and hallucinations



g 6—Coronal section 5 cm. posterior to frontal pole (case 17): V ventricle. (Tracing from myelin-stained section.)

Our thanks are due to Dr J A. N Corsellis, neuropathologist to Runwell Hospital for neuropathological reports and to Dr Graham Foulds, senior psychologist to the hospital, for psychological investigations We are also greatly indebted to Dr S Wiseberg registrar at the hospital for assistance in the preparation of case histories and follow up interviews

This report describes thrush œsophagitis in two new born infants in whom a disorder of swallowing led to aspiration pneumonia Treatment with hydroxystilbamidine not previously used in this condition was effective.

Case reports

Case 1—A girl aged 17 days and weighing 6 lb 6 oz (birth weight 6 lb) was admitted on July 24 1954 with a 24 hour history of vomiting and refusal of feeds.

Her general condition was fair A white membrane from which *Candida albicans* was isolated covered the tongue and buccal mucous membrane The vomiting and refusal of feeds suggested spread of the thrush to the œsophagus Treatment with gentian violet (1% paint to the mouth, and 0 01% 4 ml three times daily to swallow) was started

During the next 3 days reluctance to feed and occasional vomiting persisted, and her general condition remained unchanged Then, on July 28, she developed bronchopneumonia, confirmed by radiography Despite a course of sulphadimidine her condition deteriorated further during the next 48 hours The oral thrush persisted, and a profuse viscid discharge now poured from nose and mouth On July 30 a course of penicillin, previously avoided because of the thrush, was started, but the downhill course continued, and it seemed that the infant had not much longer to live At this stage vomiting, inability to swallow either food or the secretions from the nose and mouth, and repeated attacks of cyanosis despite oxygen therapy were the outstanding features The pulse rate was 180 and respirations were 80 per min Feeds had to be given by œsophageal tube passed through the mouth, because the nostrils were blocked by œdema and secretions Frequent sucking out of the nose, mouth, and pharynx was necessary to save the infant from suffocation On July 31 the house physician noted in the case records "I fear the worst"

On Aug 1 sulphadimidine, penicillin, gentian violet, and œsophageal feeds were discontinued, and an intravenous infusion was started At 10 P M the first dose of hydroxystilbamidine was given 15 mg (5 mg per kg body weight) dissolved in 0 75 ml of water was injected slowly into the rubber tubing above the drip chamber This dose was repeated 12-hourly Next morning she had improved remarkably, her respiration was slower (64 per min) and less laboured, and her pulse rate had fallen to 140 That night, however, she had a further attack of cyanosis This led us to start a course of streptomycin in addition to the hydroxystilbamidine, because it was impossible to decide whether there was a true thrush pneumonia or a bacterial aspiration pneumonia secondary to the thrush œsophagitis and stomatitis The latter diagnosis was supported in retrospect by the isolation of a coagulase positive *Staphylococcus aureus*, sensitive to streptomycin but insensitive to penicillin, from a blood culture taken on Aug 1

During the next week the baby improved steadily The nasal discharge and obstruction cleared within 24 hours of starting treatment with hydroxystilbamidine, the oral thrush membrane disappeared rapidly, no further *C albicans* was isolated, and radiography on Aug 6 showed decreased pulmonary involvement Because of this improvement and also because signs of thrombophlebitis had appeared, intravenous fluids and hydroxystilbamidine were stopped after a 6 day course, and oral feeds were begun again She took small amounts well, but, as the feeds were increased, she again started to cough and splutter, and on Aug 8 she had an attack of cyanosis On Aug 11 fluoroscopy showed bilateral basal collapse as well as incoördination of swallowing, which caused much iodised oil to enter the tracheobronchial tree Œsophageal feeding was recommenced and again she improved, though fluoroscopy on Aug 20 showed persistence of the incoördination

On Aug 26 feeding by teat was attempted once more, and this time there was no spluttering or choking Further progress was very satisfactory The baby was discharged on Sept 19, and when she was last seen on Nov 22 her condition was excellent, she had gained 4 lb and a chest radiograph was normal

Case 2 —A boy, aged 24 hours, was admitted on Oct 19, 1954 Pregnancy and delivery normal Birth weight 7 lb A few hours after birth a generalised petechial rash had appeared.

His condition was good, and there were no other abnormal signs A blood-count showed 56,000 platelets per c mm and 6000 leucocytes (1140 polymorphs) per c mm The discovery of thrombagglutinins (Stefanini and Dameshek 1953) and leukagglutinins (Dausset et al 1954) in the sera of the infant and of his mother explained the purpura and granulocytopenia

No fresh petechiæ appeared after admission, although the platelet-count on Oct 23 was only 32,000 per c.mm On Oct 25, however, he had purulent conjunctivitis of the right eye, omphalitis, septic blisters on the face, and oral thrush Oral and conjunctival swabs grew *C albicans* A *Staph aureus*, sensitive to aureomycin but insensitive to penicillin, was also isolated from the conjunctiva The septic skin lesions, conjunctivitis, and omphalitis cleared rapidly with a 6-day course of aureomycin 20 mg 6 hourly The thrush stomatitis was t[illegible] gentian violet paint Occasional vomiting suggested spread of the thrush to the œsophagus, so the baby was also given gentian-violet to swallow

Even after aureomycin had been discontinued on Nov 1, the thrush spread further until the tongue and oral mucosa were completely covered, and on Nov 2 *C albicans* was isolated from stomach washings A blood count on Nov 3 showed 7400 polymorphs per c.mm but still only 135,000 platelets per c mm His condition gradually deteriorated

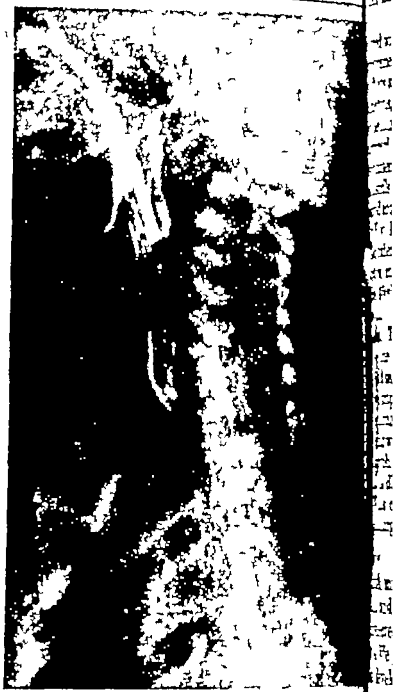

Fig 1—Case 2 Incoördinated swallowing oil has passed into nasopharynx and trach

He became reluctant to take feeds, milk was retained in mouth and dribbled from the corners, there was splutter and he had several attacks of cyanosis It was often nece to suck out his nose, mouth, and pharynx, where much mucus accumulated and interfered with breathing

On Nov 4 one of us (R A) examined the infant fl scopically the contrast medium was held in the mouth rejected, very little was swallowed If contrast me was injected into the back of the mouth or pharynx, swall was seen to be incoördinated Iodised oil passed up int nasal cavity and down the trachea, little entered the phagus (fig 1) If oil was injected directly into the œsoph it passed down reasonably well The picture was th pharyngeal incoördination of swallowing The lungs were

During the next 24 hours his condition deteriorated fu The temperature rose to 101 6°F, the pulse rate to 18 the respirations to 90 per min

On Nov 5 local treatment to the mouth was disconti and intravenous fluids were substituted for oral feeds S taneou treatment hydroxy bamidin mg 12 ho was start being give the sa method as case 1 Th improveme during th next 2 da was remark able Afte hours trea ment wit hydroxys bamidin cultures fr oral swabs stomac washings d not grow *albicans* Th oral membr started to p on Nov 7, by Nov 12 mouth

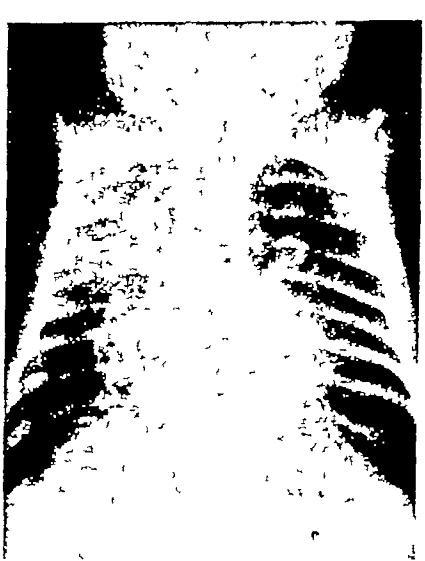

Fig 2—Case 2 : aspiration pneumonia.

vered with healthy looking mucosa. Because of this rapid provement, and also because the leg into which the intraven fluids and the drug had been given showed signs of throm phlebitis, hydroxystilbamidine was stopped on Nov 9 and l feeding restarted Within 24 hours all the symptoms of ryngeal incoördination recurred with reluctance to feed spluttering *Frequent suction of secretions from the mouth* nostrils was necessary Oral feeding had obviously been arted too soon.

On Nov 13 the baby developed pneumonia: a radiograph wed extensive consolidation in both lungs, consistent with ration into the bronchial tree (fig 2) A blood-count wed 4500 polymorphs per c.mm and 320 000 platelets r c.mm *Staph aureus* was isolated from oral and nasal retions. Treatment with streptomycin and erythromycin, which the organism was sensitive was started The infant nursed in oxygen and tube fed. After an anxious few days gain improved and fluoroscopy on Nov 22 showed a mal though rather slow swallowing reflex. Consequently al feeding was restarted and further progress was uneventful. radiograph on Dec 8 showed resolution of the consolidation, d he was discharged on Dec 11 When he was last seen on c. 22 his condition was excellent and he had gained 2lb e discharge.

Discussion

cidence

Thrush infections are common during early infancy dlam and Henderson (1942) swabbed the mouths of unselected infants at intervals during the first ten ys of life they isolated *C albicans* from 11 all of om developed clinical thrush a further 3 infants, king a total of 23% developed thrush before leaving pital. Anderson et al (1944) found an incidence of 7% of clinical thrush in newborn infants and like dlam and Henderson noted that, whenever *C albicans* s cultured thrush developed in two or three days. e use of antibiotics has made thrush infections even re frequent (Amhe 1952 Holzel 1953 Nikolowski 1953) commonly these infections are mild remain localised the mouth or skin and respond readily to gentian let or to borax in glycerin Probably such mild cases en remain undiagnosed and recover spontaneously t infrequently however the infection takes a less lign course spreads beyond the mouth into the rynx oesophagus larynx, and bronchi or rarely into lungs or blood-stream, and may kill the infant

bbs (1938) at the Children s Hospital, Birmingham found ng a three-year period 23 instances of thrush oesophagitis cropsies on infants. He regarded the thrush as the cause ath and not as a terminal complication of some other dition. Ludlam and Henderson (1942) over a four year d found 20 cases of thrush oesophagitis at necropsy The nce in infants who died after forty eight hours of life 6 6%. The thrush appeared to be the cause of death in cases. In another series, of 2, 10 infants who survived for e than forty-eight hours the same observers found 163 of thrush. 20 of these died from various causes necropsy done in 18; in 8 the thrush had spread to the pharynx l in 7 of these it had also invaded the oesophagus In 2 es it had spread to the stomach Lederer and Todd (1949) nd either pharyngeal or oesophageal thrush in 7 of 28 opsies on newborn babies and in 10 of 170 necropsies on ants 1–12 months old

Whereas the diagnosis of oral thrush is usually easy in thrush in early infancy is often unrecognised par ularly when it occurs without oral thrush The atest difficulties however arise in the diagnosis of ush involving the pharynx oesophagus, larynx or respiratory tract below the larynx The *British dical Journal* (1950) stated that the diagnosis of [illegible] thrush is a matter of conjecture and can nerally be made with certainty only after death derer and Todd (1949) thought that the diagnostic ficulties in the living and even at necropsy might be ponsible for fatal thrush lesions remaining undetected d unrecorded In the presence of oral lesions a deteri ation in an infant s condition will suggest extension of e thrush; but pharyngeal lesions may occur in the sence of or with only inconspicuous oral thrush

Clinical Features

In view of the difficulty of exact definition of the extent of the thrush infection, we shall for convenience refer to the syndrome as "thrush oesophagitis," realising that the pharynx and respiratory tract may also be involved Ebbs (1938) Ludlam and Henderson (1942) Adams (1944) and Lederer and Todd (1949) described the clinical features of this syndrome Their descriptions agree closely with each other and with the findings in our cases

Initially there is crying during feeds and regurgitation or vomiting, which is occasionally projectile, the vomit may contain blood. Then feeds are refused or retained in the mouth and dribble from its corners, much thick mucus accumulates in the mouth and nose Despite correction of dehydration an intense toxæmia develops often with a subnormal temperature During feeds attacks of cyanosis occur which Ebbs (1938) ascribed to aspiration of vomit Lederer and Todd (1949), however postulated pharyngeal incoördination leading to direct entry of milk into the respiratory tract. This hypothesis we have been able to prove by fluoroscopy and by ciné-radiography by the technique described by Astley (1955),

In both children there was a disorder of deglutition largely restricted to the pharynx transit through the oesophagus was relatively normal and only hindered by respiratory distress. Much of the opaque medium remained in the pharynx for some seconds contrasting strongly with the normal rapid passage The pharyngeal space remained open and its communicating passages patent; the larynx did not rise and the nasal cavity was not closed off by the soft palate In consequence iodised oil passed upwards into the nose and downwards into the larynx and tracheobronchial tree During much of the time the epiglottis remained erect amidst the contrast medium There was not however an absolute paralysis; occasionally the larynx rose and the pharyngeal space was obliterated Infrequently a bolus passed much more normally and the epiglottis turned down with it in the usual manner (Ardran and Kemp 1952)

These findings suggest that the pneumonia, which has been regarded by previous writers as such a constant terminal event (Ebbs 1938 Ludlam and Henderson 1942 Glanzmann and Riniker 1950) is at least sometimes due to a complicating disorder of swallowing A true thrush pneumonia is probably rare (Adams 1944 *British Medical Journal* 1950) the causal organisms usually being secondary pyogenic invaders, particularly *Staph. aureus* (Ludlam and Henderson 1942, Adams 1944, Lederer and Todd 1949, Glanzmann and Riniker 1950, Amhe 1952)

Treatment with Hydroxystilbamidine

Hydroxystilbamidine is one of the series of aromatic diamidine compounds synthesised by Ashley and Harris (1946) in the laboratories of Messrs May & Baker Fulton (1944a) found it of prophylactic value against *Trypanosoma rhodesiense* inoculations in mice In *Leishmania donovani* infections in golden hamsters it was as effective as stilbamidine (Fulton 1944b) Hydroxystilbamidine has been used in the treatment of multiple myeloma (Snapper 1948) kala azar (Sen Gupta 1949) mucocutaneous leishmaniasis (Snapper 1952) blastomycosis (Snapper and McVay 1953, Smith 1953 Colsky 1954 Sutliff et al 1954 Weinberg et al. 1954) and a coccidioidal infection involving a single bone (Grebe 1954) Trigeminal neuropathy, which is a relatively frequent and distressing complication of stilbamidine treatment (Napier and Sen Gupta 1942 Collard and Hargreaves 1947, Schoenbach and Greenspan 1948) and led Snapper et al (1952) and Curtis et al (1954) to abandon its use has not been reported after treatment with hydroxystilbamidine

We have not found an account of thrush infections in man treated with stilbamidine or hydroxystilbamidine A trial of these compounds was suggested by their success in other mycotic infections Solotorovsky et al (1954) showed that stilbamidine and hydroxystilbamidine are moderately active against *C albicans* in vitro but inactive in mice However, failure of a drug to cure fungus infections in mice does not necessarily imply failure in man For example, Schwarz and Adriano (1953) failed to arrest experimental blastomycosis in mice with stilbamidine, yet in human infections its value is beyond doubt Schoenbach and Greenspan (1948), in their excellent review of the aromatic diamidines, state that the host drug relationship is as important as the host parasite and parasite drug relationships Smith (1953) and Snapper and McVay (1953) expressed similar views

The pharmacology of hydroxystilbamidine has been reviewed by Snapper et al (1952) and Smith (1953) The following brief account is largely based on these reviews and that of Schoenbach and Greenspan (1948), which deals with the aromatic diamidines in general

Hydroxystilbamidine is 4 4′ diamidino 2 hydroxystilbene The compound used in our cases was 4 4′ diamidino 2-hydroxystilbene di β hydroxyethanesulphonate, which contains 54% of base For brevity we have used the term hydroxystilbamidine in place of the full chemical name of its salt After an intravenous dose of 2 mg of stilbamidine or hydroxystilbamidine per kg body weight only about 15% is excreted in the urine in twenty four hours After daily doses for seven or eight days the amount excreted in the urine increases progressively to a maximum of 70–80% in twenty-four hours, this suggests that the body proteins gradually become saturated with the diamidines, after which the excess is largely excreted in the urine It is likely that the remarkable adsorptive qualities of the diamidines account for the progressive improvement which may take place long after cessation of therapy *Snapper et al (1951) found traces of diamidines in the body three years after administration*

Administration—Sen Gupta (1949) and Grebe (1954) observed that hydroxystilbamidine given intramuscularly caused pain at the site of injection, Smith (1953) condemned the intramuscular route for the same reason and as a possible cause of local necrosis The intravenous route appears preferable, though Snapper and McVay (1953) noted little pain or tissue reaction after intramuscular injection with procaine (75 mg of hydroxystilbamidine in 2 ml of 5% glucose in physiological saline solution containing 20 mg of procaine) Snapper (1948) and Sen Gupta (1949) dissolved hydroxystilbamidine in 10 ml of water and 25 ml of 25% glucose respectively and injected it slowly into a vein Snapper (1952), Smith (1953), Colsky (1954), Grebe (1954), and Weinberg et al (1954) gave 225 mg daily (the dose for adults) dissolved in 200–300 ml of 5% dextrose or of saline solution by continuous intravenous drip over periods ranging from half an hour to three hours Continuous drip is probably preferable to intravenous injection, which may be followed by thrombophlebitis After rapid injection transient pallor, dizziness, a fall in blood pressure, and tachycardia have been reported (Schoenbach and Greenspan 1948, Smith 1953)

Published reports deal mainly with adults, and we have been unable to find an account of hydroxystilbamidine used in infants At this age daily intravenous injections are difficult to give In our two cases we discontinued oral feeds, administered fluids by continuous intravenous drip, and injected the hydroxystilbamidine (15 mg in 0 75 ml of water) slowly into the rubber tubing above the drip chamber The occurrence in both infants of venous spasm after injection, and later of thrombophlebitis, suggests that it might be better to give the compound by continuous drip over two or three hours

Smith (1953) noted that a precipitate forms when concentrations greater than 0 5% of stilbamidine are added to human serum, and suggested that this may explain the occasional immediate toxic effects after intravenous injection of concentrated solutions We also noticed a precipitate in the drip chamber when hydroxystilbamidine was injected into the rubber tubing while plas[illegible] being infused, though our infants showed [illegible] toxic effects After this observation the hydroxystilbamidine was injected into glucose and saline solutions, with which no precipitate formed

Dose—The dose commonly recommended for adul 3–5 mg per kg body weight daily or on alternate da As infants usually require relatively greater amount chemotherapeutic agents, we decided on a dose of 5 per kg, and the infants' very poor condition led us repeat the dose twelve hourly Treatment was contin for six and four days respectively (total doses 180 in case 1 and 120 mg in case 2) Because of the rate of excretion of hydroxystilbamidine, the rapid appearance of the thrush lesions, and the developme thrombophlebitis we decided against a longer cours treatment The optimum therapeutic régime will onl discovered after further trials of hydroxystilbamidi in severe thrush infections Our experience with the two cases has convinced us that such trials are just whenever the response to simpler remedies is uns factory, especially when the infection has spread be the skin or the mouth

Adjuvant Therapy

As secondary pyogenic invasion is important, it advisable in the more severe cases to use a potent bacterial agent in addition to hydroxystilbamidine in case 1, where streptomycin was given The disapp ance of the thrush membrane from the mouth must be taken as evidence that there can be a return to feeding, this mistake, which we made in both ca led to the development of pneumonia There wa latent period between the disappearance of the membr and the return of normal deglutition—an observatio not recorded previously, probably because before advent of hydroxystilbamidine no such seriously infant had survived It appears advisable to fo intravenous feeding, which is necessary at the heig the illness, by a period of tube feeding We sug that after the disappearance of the thrush memb *fluoroscopy should be employed to demonstrate* no *swallowing before oral feeds are restarted*

Summary

A severe thrush infection of the upper alimentar respiratory tracts may be accompanied by a c picture due to incoordination of swallowing

This incoördination may lead to pneumonia

Hydroxystilbamidine was an effective form of tr ment in the two cases described

Secondary pyogenic invasion is an important comp tion requiring additional treatment

Disordered swallowing may persist for several after the disappearance of the thrush membrane fr the mouth, fluoroscopy is advisable before reco mencing oral feeding

We are indebted to Dr H S Baar for suggesting demonstrating the presence of leukagglutinins and thr agglutinins in case 2, and to Dr W R Thrower who first d our attention to the possible value of hydroxystilbamidi thrush and helped us with case 1 We gratefully acknow the invaluable nursing services of Sister J Woodward her staff Messrs May & Baker supplied the hydrox bamidine

Addendum

Since submitting this report for publication we have tre a third infant suffering from thrush œsophagitis incoord tion of swallowing, and aspiration pneumonia The c was 3 weeks old Hydroxystilbamidine was given d over two to three hours by continuous intravenous drip a scalp vein The compound was given twice daily for days No thrombophlebitis occurred and we were abl use the same vein throughout this period The baby m an excellent and rapid recovery

The heterocyclic sulphonamide 2 acetylamino 1 3 4 thiadiazole-5-sulphonamide (acetazoleamide Diamox, Lederle), inhibits the enzyme carbonic anhydrase, its main pharmacological effect being exerted on the renal tubule cells (Miller et al 1950 Berliner et al 1951) leading to increased urinary excretion of sodium potassium, and bicarbonate reduced excretion of ammonium ion, a rise in pH of the urine and a fall in the serum-bicarbonate level and in pH of the blood (Nadell 1953 Counihan et al. 1954)

The treatment of respiratory acidosis with acetazoleamide was suggested by Nadell (1953) who obtained favourable results in 6 cases Similar results were obtained by Heiskell et al (1954) in 4 ambulant patients with pulmonary emphysema and by Ruskin (1955) in a case of cor pulmonale

The rationale of this therapy was elaborated by Nadell (1953). She found in 2 controls and in 5 of 6 patients with respiratory acidosis that when acetazoleamide was first given both the serum bicarbonate level and the pH of the serum fell with continued therapy the pH returned to normal but the serum bicarbonate level remained low This must have been due to a fall in the partial pressure of carbon dioxide in the blood (pCO_2) produced by respiratory compensation for the metabolic acidosis. Nadell commented that pulmonary dissipation of carbon dioxide seemed to be more effective after the administration of acetazoleamide but the mechanism is obscure

Some criticism of this argument might be advanced In respiratory acidosis the respiratory centre is already relatively insensitive to the stimulus of a high pCO_2 the ventilatory function of the lungs is so impaired that alveolar loss of carbon dioxide cannot be significantly increased despite additional stimulation of the respiratory centre (Wilson et al. 1954 Cohn et al 1954) and urinary loss of bicarbonate in response to the administration of acetazoleamide would tend to alter the ratio of serum bicarbonate to pCO_2, with a fall in pH which is potentially harmful to a patient who is already acidotic

Despite these theoretical objections we have given acetazoleamide to 3 patients with acute respiratory acidosis in the hope of preventing or relieving carbon dioxide narcosis. The patients all had chronic bronchitis emphysema and pulmonary heart-disease and their symptoms had been severely aggravated by acute respiratory infection. Striking biochemical changes took place in all the patients after the administration of acetazoleamide but no clinical improvement was noted Judged clinically the condition of the 1st patient was deteriorating before acetazoleamide was given the drug did not influence the course of the disease and the patient died In the 2nd patient the administration of acetazoleamide was immediately followed by much clinical deterioration a rapid downhill course ending in death The 3rd patient showed an alarming deterioration of the clinical condition after a single dose of acetazoleamide but improved when the drug was withheld

Case reports

Case 1 —A woman aged 59 was admitted to hospital with a severe acute respiratory infection She had chronic bronchitis of five years duration, and this was now accompanied by emphysema and pulmonary heart-disease On admission she was pyrexial, dyspnœic and cyanosed but conscious and rational.

Treatment and Course—She was treated with penicillin digitalis, and mersalyl and oxygen was given in small amount by nasal catheter with relief of cyanosis. Next day her general condition gradually deteriorated and she became comatose Her optic fundi showed gross distension and tortuosity of veins and congestion of the optic discs. Her serum bicarbonate level was 37 8 m.eq per litre and her serum urea level was raised but her serum potassium level was normal and remained so throughout the illness. She was given acetazoleamide 500 mg on the day after admission and the same dose was given daily for the next three days, and then every second day for three more doses. Eighteen hours after the first dose of acetazoleamide the serum bicarbonate level had fallen to 29 7 m.eq per litre but no clinical improvement was noted The serum bicarbonate level in the next ten days ranged from 32 4 to 41 8 m.eq per litre Oxygen therapy was continued by intermittent use of the oxygen tent and oxytetracycline was given The patient remained critically ill, with pyrexia dyspnœa and drowsiness, and four weeks after admission she lapsed into coma and died

Necropsy showed chronic bronchitis, emphysema recent bronchopneumonia right ventricular enlargement and congestive cardiac failure

Case 2 —A woman aged 63 with nine years history of chronic bronchitis, was admitted to hospital with an acute exacerbation of pulmonary heart disease following an infection of her upper respiratory tract On admission she was cyanosed and dyspnœic but conscious and rational

Treatment and Course—Penicillin and digitalis were administered but oxygen was at first withheld On the day after admission the serum bicarbonate level was 36 0 m.eq per litre The optic fundi showed dilatation and tortuosity of the veins, and the discs were slightly swollen. Oxygen therapy was started by nasal catheter and acetazoleamide 500 mg was given. Twenty four hours later the serum bicarbonate level had fallen to 32 4 m eq per litre and in that period the patient excreted 705 ml of urine containing 31 5 m.eq of bicarbonate On the second day after admission the patient became drowsy and confused and was placed in an oxygen tent She was given acetazoleamide 500 mg twice on that day and once more on the third day the serum bicarbonate level then having risen again to 30·0 m eq per litre The serum potassium level was normal Her condition rapidly deteriorated the drowsiness deepened into coma and she died on the third day after admission

Necropsy showed chronic bronchitis and
recent pneumonic lesion fatty infiltration of
and enlargement of the right ventricle
cerebral oedema but no local lesion in the

Case 3 —A woman aged 60 with
chronic bronchitis with emphysema a

disease, was moderately ill when admitted for treatment of an acute respiratory infection.

Treatment and Progress—She improved under treatment with penicillin, digitalis, and oxygen given by nasal catheter Her serum bicarbonate level on admission was 49 5 m eq per litre, the level fell to 38 3 m eq per litre next day, but rose on the third day to 40 5 m eq per litre Acetazoleamide 500 mg was given on the third day In the next twenty four hours the patient excreted 1055 ml of urine containing 100 m.eq of bicarbonate, and the serum-bicarbonate level fell to 36 9 m eq per litre No more acetazoleamide was given, but renal excretion of bicarbonate continued for two more days, a further 62 m.eq of bicarbonate being excreted. This was accompanied by a further fall in serum bicarbonate level to 34 2 m eq per litre and 30 6 m eq per litre two and three days respectively after the administration of acetazoleamide Twenty four hours after the acetazoleamide had been given there was an unexpected serious deterioration in the patient's clinical condition respiration became shallow, cyanosis increased, and she became extremely drowsy She was placed in an oxygen tent, where she remained drowsy, confused, and breathless for two days, and then gradually improved During this time the physical signs in the chest were unchanged, the retinal veins were tortuous and congested, but there was no papillœdema, and the serum potassium level was normal Oxygen therapy was discontinued after three days, and the patient eventually made a good recovery The serum bicarbonate level was estimated every second day in the next week as 38 7, 32 0, and 37 8 m.eq per litre

Discussion

The clinical deterioration in these 3 patients depended on a combination of toxæmia, hypoxia, and retention of carbon dioxide Toxæmia played an important part in case 1, but in the 2 other patients the infection responded initially to treatment with an antibiotic Anoxia was present in all the patients, and our policy was to relieve this gradually, following the advice of Simpson (1954) by giving oxygen at first by nasal catheter at a rate of flow of 2–4 litres a minute, and only later transferring the patients to an oxygen tent Retention of carbon dioxide was probably a major factor leading to deterioration, and oxygen therapy may have contributed to this

In any attempt to measure the effects of retention of carbon dioxide the relevant physiological observations are the alveolar concentration of carbon dioxide and the pH of the serum, from which can be determined the pCO_2 It is unfortunate that it was impossible to obtain these measurements in our patients The serum bicarbonate level gave no indication of the clinical condition Case 2 was very much more ill, with an initial serum-bicarbonate level of 36 0 m eq per litre, than was case 3, whose serum-bicarbonate level on admission was 49 5 m eq per litre Considerable fluctuations in the serum-biocarbonate level in case 3 have already been noted, these were independent of treatment and unrelated to the clinical condition There seems to be no doubt, however, that acetazoleamide caused an initial fall in the serum-bicarbonate level in all 3 patients The lack of clinical improvement suggests that the fall of the serum-bicarbonate level was not accompanied by a corresponding fall in pCO_2, presumably because of pulmonary insufficiency We cannot offer direct proof of this hypothesis, but, if it is true, the initial effect of acetazoleamide in these patients was to alter the ratio of pCO_2 to serum-bicarbonate in such a way as to cause a potenti ally dangerous fall in serum pH There is ample evidence that this happens when acetazoleamide is administered to patients with normal respiratory function (e g, Nadell 1953, Counihan et al 1954), and Simpson has demonstrated that the same mechanism operated in his own cases of respiratory acidosis The rapid return of the serum bicarbonate level to its initial high value in cases 1 and 2 was not accompanied by improvement, possibly bec respiratory centre remained adversely affected by the persistently high pCO_2 or as a result of t temporary lowering of pH

We conclude that in these 3 cases of acute re acidosis accompanied by pulmonary infection aceta amide was of no value, and that its property of prom ing renal excretion of bicarbonate may have been har to the patients

Summary

The carbonic anhydrase inhibitor, acetazoleamide, given to 3 patients with acute exacerbation of respiratory acidosis

Increased urinary excretion of bicarbonate and of the serum bicarbonate level resulted

In all 3 cases there was clinical deterioration 2 patients died, and the 3rd recovered when the amide was withheld

It is concluded that acetazoleamide may be de in acute respiratory acidosis

We wish to thank Prof Stanley Alstead and Dr J Macarthur, under whose care these patients were treated, their advice and encouragement, and Dr J W and Dr A W Mollison for the biochemical estimations.

TUBERCULIN AND LEPROMIN SENSITIVITY IN THE SOUTH AFRIC BANTU

A PILOT SURVEY

S W A Kuper
M B Rand, D P H., D T M & H, D C.P
CLINICAL PATHOLOGIST, BROMPTON HOSPITAL, LOND

It has often been stated that skin sensitivit tuberculin and lepromin are correlated, and it has inferred that this reflects an immunological relatio (Chaussinand 1950, Fernandez 1943, Lowe and Mc 1953b)

The significance of skin sensitivity to lepromin i clearly established, and this sensitivity is used as an to classification and prognosis in leprosy rather tha a means of diagnosis Most patients with leproma leprosy are relatively insensitive to lepromin, whe those with tuberculoid leprosy are said to show a marked allergic response, which may be either a "tu culin like" reaction at forty-eight to seventy two h (the Fernandez test) or an indurated nodule from tw five weeks after the inoculation The two types of r tion are said to parallel one another in the individ case (Fernandez 1940, Lowe and McNulty 1953b), but method of preparation of the antigen determines whe the early or the late reaction is the greater Much of published material on this subject is largely speculati but a good deal of the data appears to support the th that the degree of correspondence between tuberc and lepromin reactions is far greater than could accounted for if the two forms of sensitivity were co pletely unrelated

I describe here an attempt to elucidate some of the problems by tests on South African Bantu patients controls Patients with pulmonary tuberculosis others with leprosy were investigated together wi apparently healthy adults The numbers tested were

TABLE I—MEAN SIZES OF REACTIONS

Group	No of persons	Mean transverse diameter of reaction (standard error of mean)					
		Tuberculin at 48 hr	Nil reactors	Lepromin at 48 hr	Nil reactors	Lepromin at 4 weeks	Nil reactors
ntrols (adult males)	105	12·5 mm. (*0·48*)	6	3·6 mm (*0·34*)	8	3·7 mm. (*0·16*)	1
berculosis (adult males)	53	14·1 mm (*0·79*)	1	7·4 mm (*0·77*)	2	3·9 mm (*0·30*)	1
promatous leprosy (adult males)	33	16·6 mm (*3·18*)	1	3·4 mm (*0·53*)		1·6 mm. (*0·34*)	13
romatous leprosy (adult females)	15	21·0 mm (*6·63*)	1	2·5 mm (*0·31*)		0·7 mm (*0·19*)	7
berculoid leprosy (adult males)	25	10·6 mm (*1·14*)	3	15·0 mm (*1·41*)		7·2 mm (*1·19*)	2
berculoid leprosy (adult females)	12	5·0 mm (*1·23*)	2	8·8 mm (*1·60*)		5·8 mm. (*1·31*)	1
berculoid leprosy (male children)	7	6·0 mm (*3·20*)	3	11·6 mm (*3·56*)		5·4 mm (*2·11*)	2
berculoid leprosy (female children)	6	3·2 mm (*1·44*)	2	10·2 mm. (*3·12*)		6·2 mm (*2·36*)	

This table represents the mean transverse diameters of reactions recorded in all the groups of patients It lists the reactions to tuberlin at 48 hours, and to lepromin at 48 hours and at 4 weeks The standard error of the mean is included in parentheses after each result numbers of subjects in whom no reaction was found are given in a separate column, but they are included in the figures of totals for h group

ps but it was hoped that this disadvantage would be ercome by careful standardisation of methods (Guld d Rud 1953 Meyer et al 1951)

Methods

The persons tested were divided into three categories

Group 1—Patients with pulmonary tuberculosis (57 adult ales)

Group 2—Patients with leprosy (102 mostly adults but me children aged 10–16 years)

Group 3— *Controls* (*114 adult males*)

The patients with tuberculosis were in hospital during e trial. They showed no obvious evidence of leprosy adiographs of the chest were characteristic of pulmon y tuberculosis and tubercle bacilli had been isolated m the sputum in about 90% of the cases

The leprosy patients were all being treated in an stitution during the trial, and radiological examination thin the preceding few months showed no evidence of lmonary tuberculosis The clinical diagnosis of leprosy d in all cases been substantiated by examination of ne smears and the type of leprosy was classified by e experienced permanent medical staff of the institute sts were made in 52 patients with lepromatous leprosy d 50 with tuberculoid leprosy

The controls consisted entirely of adult industrial ployees working in a soap factory and resident in the y Within a few weeks of the start of the trial they were diographed to exclude anyone with a shadow suggesting lmonary tuberculosis No obvious evidence of leprosy s seen in any member of the group

So far as is known none of the persons in any group d ever received B C G vaccine

chniques

Dried *lepromin* of the Dharmendra type was prepared by . N Figueredo of the Acworth Leprosy Home Bombay his antigen produces more prominent early reactions than layed ones, and is therefore more strictly comparable to berculin than is the Mitsuda type of antigen. The lepromin s finally suspended in half the recommended volume of line solution to reduce the volume of the intradermal injec on from 0·2 ml to 0·1 ml It was sealed in ampoules in eat Britain and was used within a month of the date of lling

Tuberculin was used in the form of purified protein rivative It was dissolved and diluted so that 0·1 ml ntained 5 tuberculin units. It was thought that this small se of tuberculin would detect only high specific degrees of nsitivity (Palmer and Bates 1952 Palmer 1953) Tablets re dissolved freshly for each session of inoculations.

Syringes were of the all glass tuberculin type All the ringes were new and each was used for only one inoculating ssion to prevent possible transference of antigen Only new edles were used and they were discarded at the end of each ssion. The syringes were examined for leakage and the iteria recommended by Guld and Rud (1953) for field trials were adopted 48 syringes were tested by their method but nly [illegible] satisfied their requirements. Fortunately it was found that a light smear of silicone oil applied to the barrol of the syringe reduced leakage to such a degree that 37 out of 48 syringes could be used Several intradermal inoculations of water made with these syringes in hospital staff produced no evidence of sensitivity to the silicone oil

Procedure

All the inoculations and readings of results were made by me to minimise individual variations of judgment (Meyer et al 1951) All the controls were inoculated on one day and all the patients with leprosy and tuberculosis on another The injections were made in the skin of the ventral surface of the forearm about half way between the wrist and elbow The volume inoculated was in all cases 0·1 ml administered intradermally so as to raise a distinct bleb in the skin Lepromin was injected into the left arm and tuberculin into the right each patient received the two inoculations within a few minutes

Because of skin pigmentation in the patients no attempt was made to delimit areas of erythema Measurements were made of the induration produced the edges of the areas were carefully defined, and the transverse diameters measured in millimetres with a transparent rule The site of inoculation of the tuberculin was examined after forty eight hours that of the lepromin inoculation was examined at forty eight hours, and after one two three, four five and six weeks

Results

Table I shows that the tuberculous and the control groups consisted entirely of adult males, but the leprosy patients included adults and children of both sexes. Distinct variations are apparent between males and females and adults and children so the results are recorded under separate headings In figs 1–3 the sexes and ages are not separated

The numbers of subjects vary slightly from table to table depending on the numbers available for measurement on the day in question The controls for example were 114 after forty eight hours but only 105 of these presented themselves for examination on the twenty eighth day

The results may be examined in one of two ways In the first place evidence may be sought of any correlation between skin sensitivities to lepromin and tuberculin This is best elicited statistically by the examination of product moment correlations but dot diagrams give an approximate picture of the relationships (*fig 1*) (The product moment correlation takes into account the sizes of reactions in each patient and may be regarded as a statistic summarising the degree of association exhibited in the dot diagrams) In this investigation no correlation between the two forms of sensitivity was found in 105 controls nor was there any evidence of association in the 85 adults with leprosy In the 53 patients with pulmonary tuberculosis, however a definite positive correlation was obtained (product moment correlation = 0·40 The chance of this being a random result is less

1000)* A small positive correlation was also found between the tuberculin reactions at forty-eight hours, and the lepromin reactions at twenty-eight days It is smaller than the forty-eight-hour correlation, and possibly merely residual from it The need for caution in assessing the importance of the observation is emphasised by the failure to find any correlation between the tuberculin and lepromin reactions in the other two test groups

The results may also be examined in another way If the suggestion is accurate that there are antigens common to the tubercle and leprosy bacilli, one might expect to find skin hypersensitivity in each of the two diseases, to the causal organism of the other, or to products derived from it Patients with tuberculosis might react strongly to lepromin injection, and patients with leprosy to tuberculin This could never be more than an approximation, however, for lepromin hypersensitivity is far less regular, even in leprosy, than is tuberculin sensitivity in tuberculosis

Skin reactions to lepromin (examined at forty-eight hours) were compared in healthy adults and in patients with pulmonary tuberculosis The latter were found to be significantly more sensitive to lepromin than the controls (mean for tuberculous patients 7 4 mm, and for controls 3 8 mm), and the same trend is evident in histograms (fig 3) †

Conversely, skin reactions to tuberculin were compared in healthy adults and in patients with leprosy The picture is rather complex Patients with tub leprosy appear to react less strongly to tuberculin th do the normal controls (fig 2) This difference is siderably reduced, however, if the male patients are compared with the controls, all of whom were ma The mean size of reactions in the male patients wi tuberculoid leprosy was 10 6 mm, and that in the norm controls 12 5 mm The difference is not significant Th female leprosy patients cannot properly be compar with the male controls In lepromatous leprosy th measurements are widely scattered, the mean reactio however, are significantly greater (males, mean=1 mm) despite the fact that 12 members of this gro showed no reactions at all to tuberculin (fig 2) Th was a very high degree of tuberculin sensitivity in so members of this group

Much of the published work on skin reactions in lepro records the observed reactions in terms of an arbitrar scale of "positive" and "negative" reactors. So

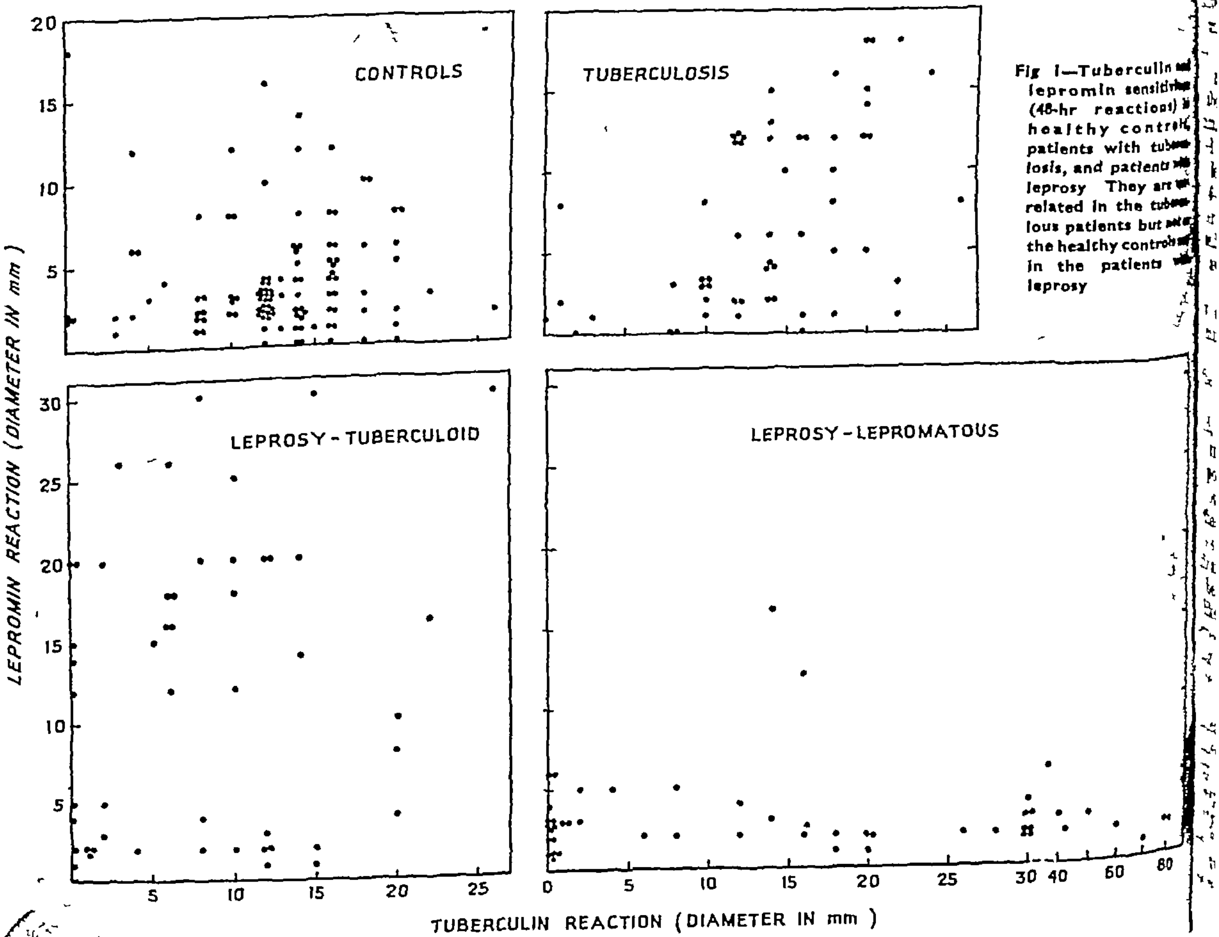

Fig 1—Tuberculin and lepromin sensitiv (48-hr reactions) healthy contr patients with tub losis, and patients leprosy They are related in the tub lous patients but the healthy contro in the patients leprosy

---

* *Validity of Tests Used*—In comparing mean sizes of reactions *between the various groups, and in assessing the* significance of correlation between the reactions obtained to the two antigens, statistical tests were used which depend for their validity on the normal (gaussian) distribution of the measurements Evidently this type of distribution is not fulfilled, so the tests must be regarded as having only an approximate significance

† In figs 2 and 3 data relating to the forty eight hour tuberc and lepromin reactions are shown as histograms The gro intervals have been judiciously chosen to conceal th tendency towards recording even numbers of millimet *particularly in measuring* the relatively large reactio Superimposed on the histograms of the controls are th fitted logarithmic normal distributions, reached disregarding the information on reaction diameters than some arbitrarily selected level—8 mm in the c of tuberculin reactions, 1 5 mm in the case of lepro reactions (Hald 1952a and b)

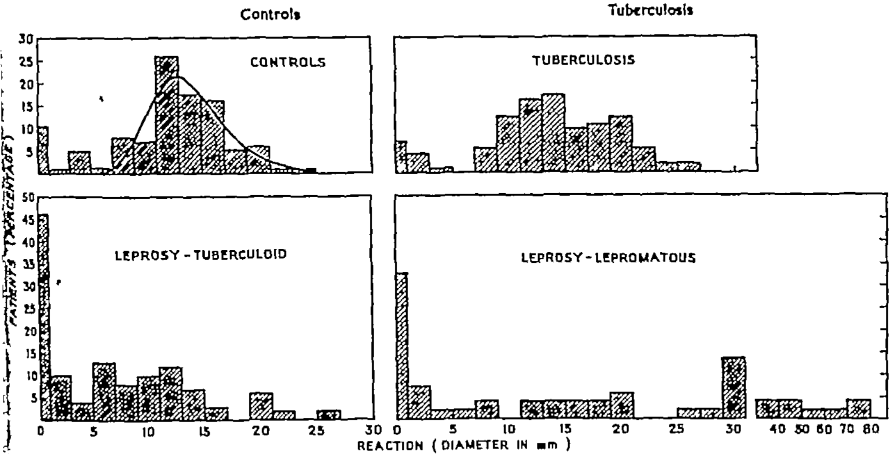

Fig 2—Tuberculin sensitivities (48-hr reactions) in healthy controls patients with tuberculosis and patients with leprosy

andards provide a useful rule of thumb for clinical urposes but their adoption in a survey of immunological actions leads to the discarding of a great deal of the formation (Edwards et al 1953) This trial records the tual observed measurements but it is possible to divide e readings at any desired level to facilitate comparison ith results published only in terms of 'positives' and negatives' Such comparison is obviously of limited lue unless conditions in the two surveys are very milar

Table II represents the results of this trial analysed the above lines Tuberculin reactions with a diameter 6 mm or more are corded as 'positive' lepromin reactions 0–10 mm. in ameter as 'doubtful' and 11 mm or ore as positive These criteria for rty eight hour promin reactions ere recommended y the International eprosy Congress in adrid 1953) In ble II 'doubtful' nd "positive" results re grouped together y this method of nalysis the results are gnificant only if it an be shown that e likelihood of the bserved distributions aving occurred by hance is less than 20 This level of gnificance was not ttained by any of the roups in this series.

Despite the possibility of errors in classification between the types of leprosy the results for the two groups are not 'combined' for any of the investigations This precaution was deemed necessary because of the widely divergent patterns of skin sensitivity in the two forms of leprosy It may be argued that the clinical classification was possibly biased by the results of earlier lepromin reactions but the pictures of tuberculin sensitivity in the two forms of leprosy are so widely different that it appears to reduce to a minimum the likelihood of widespread misclassification of the type of disease.

Early and Late Lepromin Reactions

The forty-eight-hour lepromin reaction is not significantly different in controls and in patients with lepro

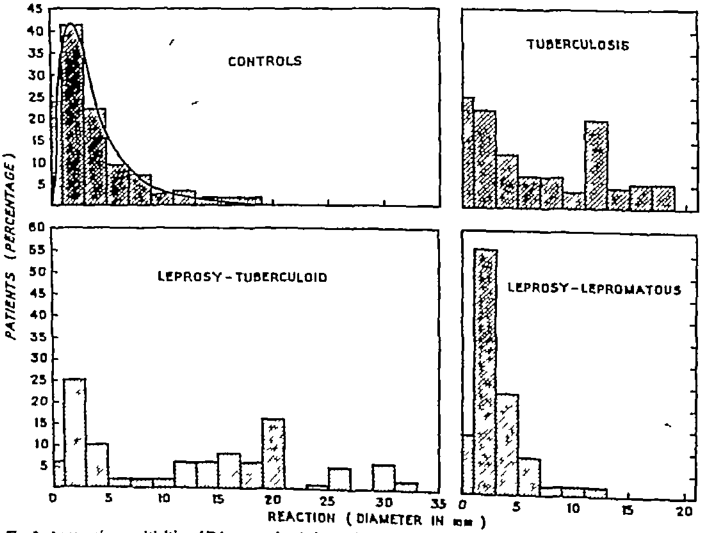

Fig. 3—Lepromin sensitivities (48-hr reactions) in healthy controls, patients with tuberculosis and patients with leprosy

TABLE II—NUMBERS OF "POSITIVE" AND "NEGATIVE" REACTORS

Group	Tuberculin negative (0–5 mm)		Tuberculin-positive (≥6 mm)		Total
	Lepromin negative (0–5 mm)	Lepromin positive or doubtful (≥6 mm)	Lepromin negative	Lepromin positive or doubtful	
Controls	8	4	80	22	114
Tuberculosis	4	1	24	28	57
Lepromatous leprosy (males)	12	1	17	3	33
Lepromatous leprosy (females)	6	2	11	0	19
Tuberculoid leprosy (males),	3	4	7	18	32
Tuberculoid leprosy (females)	7	4	3	4	18

The subjects tested are grouped in this table into "positive" and "negative" reactors, in terms of arbitrary scales, as defined.

matous leprosy, but late lepromin reactions tend to be smaller in the latter This difference may be due to inaccuracy in measuring the very small reactions In males with lepromatous leprosy there is a 90% probability that the mean twenty-eight day reaction size lies between 0 9 mm and 2 1 mm , whereas for controls at twenty-eight days the equivalent figures are 3 4 mm and 3 9 mm (table I) In adult males with tuberculoid leprosy the late lepromin reaction, as would be expected, is substantially greater than that seen in controls (mean twenty-eight day lepromin reaction 4 8–9 6 mm)

Skin reactions to both antigens in males with tuberculoid leprosy are usually larger than in females (table I) This is particularly true of the forty eight-hour tuberculin reaction This sex difference is not so clear cut in lepromatous leprosy, unless one omits the 12 males and 1 female showing no measurable reactions to tuberculin, and the 13 males and 7 females showing no reaction to lepromin at twenty eight days If a measurable reaction does result, the mean values are larger in males At twenty-eight days the trend is still present but less striking

There is some correlation between forty eight hour and twenty-eight-day lepromin reactions , but, except in the case of tuberculoid leprosy, it is smaller than might be expected (Fernandez 1940) The two reactions were not always parallel, and an appreciable late reaction was usually (but not always) preceded by a large early reaction In view of the type of antigen used, this feature is perhaps not surprising, and no emphasis can be placed on the late readings

It might prove useful to investigate late lepromin reactions on the basis of histological appearances in biopsy material from the site of inoculation This technique has been found to increase the diagnostic value of reactions to Nickerson-Kveim antigen in sarcoidosis (Siltzbach and Ehrlich 1954)

Discussion

In an investigation of this kind there are several difficulties in interpreting the results It has been claimed that tuberculin and lepromin sensitivities are positively correlated, and on the basis of this observation an immunological relationship between tuberculosis and leprosy has been postulated Such a thesis would be more easily tenable if the sensitivities involved indicated immunity in their respective diseases , but tuberculin sensitivity does not imply immunity to tuberculosis, and significant lepromin sensitivity is seen mainly, if not v, in the tuberculoid form of leprosy The be regarded as immunological factors only in so far as they reflect the capacity of the host's tissu to react to the corresponding antigens

In tuberculoid leprosy, skin sensitivity to lepromin is usually high , the disease itself is mild and self limiting suggesting a high resistance to leprosy bacilli From these observations it appears to have been inferred that high lepromin sensitivity is closely associated with high resistance , and, therefore, the production of lepromin sensitivity in uninfected people might protect them against infection For this purpose, B C G vaccination has been advocated Many workers have recorded increases in lepromin as well as tuberculin sensitivities after the administration of B C G vaccine to healthy subjects A large proportion of people with "negative" reactions to lepromin are stated to become "positive" after this measure (de Souza Campos 1953, Ferna 1943, 1951, Kocsard and Sagher 1953, Lowe and Mc 1953a) This observation is particularly intere Cochrane (1955) states that lepromin "conversion" i seen in patients with lepromatous leprosy who tuberculosis

The present investigation is not concerned with relationship of immunity and skin sensitivity, but with the possibility of there being some correlati between the sensitivities induced in man by infecti with tubercle and with leprosy bacilli In this pilot stud the degree of correlation established between tubercul and lepromin sensitivities was small, and was found on among the patients with pulmonary tuberculosis, th smallest of the three groups tested in the trial Further more the tuberculous patients showed a greater degr of sensitivity to lepromin than did the controls—thoug this may be merely a consequence of the former correlation In lepromatous leprosy, where lepromin sensitivity is slight or absent, a small proportion of the patie showed an intense degree of sensitivity to tubercul When these were excluded the two main groups of lepro patients did not show greater tuberculin sensitivity th the controls

In view of these findings there seems to be no sim and direct relationship between tuberculin and lepro sensitivities However, the observations in patients wi tuberculosis and lepromatous leprosy suggest the existe of a relationship of some kind

Summary

A pilot survey was made to investigate correlati between tuberculin and lepromin sensitivities in the South African Bantu

Three test groups were selected for the trial 10 patients with leprosy, 57 patients with pulmonar tuberculosis, and 114 healthy controls

In the controls and in the patients with leprosy no correlation could be established between lepromin and tuberculin sensitivities In the patients with pulmonary tuberculosis, however, a positive correlation was found Furthermore these tuberculous patients showed a greate degree of sensitivity to lepromin than did the contro

A small proportion of the patients with lepromatou leprosy showed a very high degree of sensitivity to tuberculin

I am greatly indebted to the medical superintendents and staff of the Westfort Institution, Pretoria, and the Waters Hospital, Johannesburg, for facilities and willing assistance to the British Tuberculosis Association for providing the lepromin, and to Dr R G Cochrane, through whose kin services it was made available , to Mr B Benjamin for his advice in planning the trial and for scrutinising the early results , to Mr P M Payne for his exhaustive statistic analyses of the complete findings , and to the Board of Governors of the Brompton Hospital for allowing a period of study leave during which this work was done Lastly, I should like to thank Dr R W Riddell and Dr J R Bignall, of the Brompton Hospital, for their advice, help, and encouragement

TRAUMATIC RUPTURE OF DIAPHRAGM WITH HERNIATION OF ABDOMINAL VISCERA

K. K. SINHA
F.R.C.S.
[illegible]

INDIRECT violence is one of the rarer causes of traumatic rupture of the diaphragm, and in most recorded cases the patient sustained gross injury to abdominal viscera. In the case described here the only abdominal organ to be injured was the spleen.

A woman, aged 45, was admitted to hospital a few hours after a car accident in which she had been thrown on to her right side and had felt a sudden snap all over the left side of her chest.

Fig. 1—Radiograph of chest showing high gastric shadow, collapsed left lung, and fractured ribs.

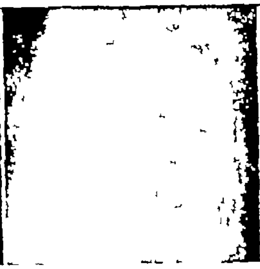

Fig. 2—Barium-swallow: œsophagus distorted and the stomach high in the thoracic cavity.

Fig. 3—Postoperative appearance: left lung re-expanded.

On admission her pulse-rate was 90 per min., blood-pressure 120/90 mm. Hg, respirations 20 per min. There was no cyanosis or evidence of respiratory distress, though she complained of pain in the left side of her chest. Bowel sounds were audible over the left hemithorax.

Radiography of the chest revealed fractures of the upper [illegible] ribs on the left side. The left lung seemed to be collapsed and the diaphragm appeared unusually high; the gastric shadow could be seen as high as the fifth left intercostal space (fig. 1). Barium-swallow showed considerable distortion of the œsophagus and confirmed the presence of stomach high up in the thoracic cavity (fig. 2).

Diagnosis.—The absence of respiratory distress was difficult to explain in view of the radiographically and clinically demonstrable collapse of the left lung. The problem was whether it was a case of congenital high diaphragm or a tear of the diaphragm with herniation of the bowel and collapse of the lung. The history of trauma along with the radiographic findings suggested a diagnosis of traumatic rupture of the diaphragm.

Progress.—The patient's general condition remained quite satisfactory. She had no difficulty in taking food, and the bowels continued to act normally for two days after admission. On the third day she started to vomit, and screening showed the [illegible] of [illegible] in the stomach. She was removed to the theatre [illegible].

Operation.—Thoracotomy was done through the bed of the eighth rib. Inside the left pleural cavity the spleen, stomach, transverse colon, [illegible] omentum, and small intestine were found. On the left side there was a large tear [illegible] from the front backwards, where the [illegible] the diaphragm [illegible] the muscular portion. The spleen was [illegible] but there was no [illegible] to suggest recent bleeding. [illegible] the chest [illegible] hæmorrhage began and splenectomy had to be done. The stomach was returned to the abdomen and the [illegible] of the diaphragm was [illegible]. The diaphragm was repaired with interrupted [illegible] stitches, and after the abdominal and thoracic [illegible] had been [illegible] the lung expanded [illegible] by the anæsthetist.

Postoperatively [illegible] recovery was uneventful, and bowel sounds returned within twenty-four hours. Oral feeds were begun within thirteen hours of operation. On the tenth day after operation the blood-pressure was 125/80 mm. Hg, and the apex beat had returned to the normal position. There was no abdominal distension. Breath sounds were clearly audible at the left base, though slightly diminished compared with the opposite side. Radiography showed satisfactory expansion and functioning of the left lung (fig. 3).

Noteworthy features in this case were that: (1) the patient's general condition remained good despite collapse of one lung and herniation of a large amount of bowel; (2) there was no evidence of shock at the time of admission; and (3) the ruptured spleen bled only when the chest was opened.

DIAPHRAGMATIC HERNIA FOLLOWING INJURY

P. A. HAMDI
M.B. Alexandria, Ph.D. Lond.
D. K. STURDY
M.B. Lond.
[illegible] DEPARTMENT OF [illegible], MORRISTON HOSPITAL, SWANSEA

IT is known that severe crushing injuries to the abdomen and chest may be responsible for rupture of the diaphragm with subsequent development of diaphragmatic hernia. Of 7 cases reported by Evans and Simpson (1950) 5 were due to severe crushing injury to the abdomen, 1 sustained bruising of the chest wall, and none had fractured ribs. Evans and Simpson suggested that the mechanism of the injury to the diaphragm was in the nature of an explosive rupture due to sudden increase in intra-abdominal pressure.

The case presented here illustrates how herniation of abdominal contents into the thoracic cavity revealed itself as an acute abdomino-thoracic emergency twenty-four hours after the injury.

Case report

A man, aged 40, was admitted semiconscious to the [illegible] surgical unit at 11.30 P.M. on May 8, [illegible], having been knocked down by a motor-car an hour previously. Immediately after the accident he had been given morphine gr. [illegible] by a [illegible] practitioner.

On admission he was easily roused but did not [illegible]. He had a laceration over the right eye [illegible] skull showed a comminuted fra

53355

right superior and lateral orbital margins and a depressed fracture of the outer wall of the frontal sinus in the midline There were no abnormal neurological signs on examination nor any signs of shock, the pulse rate being 68, respirations 20 per minute, and the blood-pressure 150/80 mm Hg There were no obvious signs of injury to the abdomen or the chest The patient had passed clear urine since the injury

Operation —At 10 A M., next day, under general anæsthesia, the supraorbital wound was cleaned and excised, the fracture involving the orbital margins was reduced, and the wound was closed in layers

Postoperative Course —On his return to the ward the patient became very restless and began to vomit what appeared to be altered blood Later in the day he complained of pain in the epigastrium and breathlessness There was no shoulder pain The pulse rate had increased rapidly to 128 and respirations to 40 per minute, while the blood pressure had dropped to 90/60 mm Hg

On examination, the patient was extremely pale and sweating profusely, with anxious facies, and lying on his right side with his knees flexed The apex beat was 2½ inches from the midline in the fifth left intercostal space The heart sounds were normal The left side of the chest was immobile on respiration and dull on percussion as high as the third left intercostal space anteriorly There was complete absence of breath sounds over this area, and no adventitious sounds were heard There was good air entry in the right lung The abdomen moved normally on respiration, there was tenderness and guarding over the left hypochondrium and epigastrium, percussion revealed a normal area of liver dullness, and bowel sounds were absent Rectal examination revealed no abnormality A provisional diagnosis of ruptured diaphragm with hæmothorax was made, and in view of the rapidly deteriorating condition of the patient immediate operation was considered advisable

Second Operation —The abdomen was explored through a left paramedian incision. There was no free fluid or blood in the peritoneal cavity A large oblique tear, 5 inches long, was felt in the left cupola of the diaphragm The region of the left kidney and splenic flexure of the colon was contused The stomach and spleen had herniated into the left pleural cavity through the tear in the diaphragm A thoracotomy with resection of the left ninth rib was next performed, this rib was found to be fractured in the mid axillary line The stomach was much dilated and thin walled, with numerous subserous hæmorrhages As it could not be reduced through the diaphragmatic tear, its contents were aspirated, three pints of coffee coloured fluid being recovered The stomach and spleen were then returned to the abdominal cavity, and the tear in the diaphragm was sutured with 'Mersilene' The thoracotomy incision was closed with drainage of the left pleural cavity, and the laparotomy incision was closed without drainage Blood (2 pints) was given intravenously during the operation

Recovery was uneventful Daily radiography of the chest showed a completely expanded left lung, with a little effusion of fluid at the left base after the fourth day this effusion gradually resolved A month later a barium meal showed no evidence of intrathoracic herniation, and radiography of the chest revealed complete expansion of the lungs

Comments

This case is of interest because the abdominal contents must have herniated into the thorax after the administration of the first anæsthetic for suturing the supraorbital margin The stomach presented the picture of acute dilatation Most of the published cases of traumatic hernia have developed insidiously, appearing from a few days to many weeks after the original injury Frequently the diaphragmatic lesion had been overshadowed by more serious intrathoracic or intra abdominal complications

We have been unable to find any reference to the enormous gastric dilatation noted in the present case It seems likely that, at the moment of injury, the diaphragm ruptured explosively owing to increased intra-abdominal pressure Later on, during the induction of anæsthesia and possibly associated with straining, the tear became large enough to allow herniation of the stomach and spleen into the thorax, and the constriction at the hernial orifice caused great dilatation of the herniated stomach

This [illegible] illustrates the importance of making a [illegible] ical examination in cases of injury to the head, not only at the time of admission but also durin the ensuing stages of return to consciousness

We are indebted to Mr Norman Whalley for permission to publish this report

Preliminary Communication

HYALINE MEMBRANE IN THE LUNGS OF THE NEWBORN

IN recent years much work has been done to elucid the nature, source, and cause of hyaline membrane i the lungs of newborn infants Farber and Wilson[1] showed that similar membrane is sometimes formed i other conditions, and Farber[2] later demonstrated th œdema and membrane could be produced in rabbits b bilateral mid cervical vagotomy Others[3-6] have s shown that various experimental procedures may prod a similar disease pattern in the lungs of animals, and it generally agreed that a number of agents and proces may lead by one or more mechanisms to a comm histopathological finding

Histochemical analyses of the membranes[3-6] as foun in premature babies and in experimental animals hav established the presence of a polysaccharide aldehyd Wagner,[7] who has carried this a stage further, believ that the membrane contains mucoprotein and that it formed from endogenous mucus derived from the na pharynx, buccal cavity, and bronchial tree of the inf Other observers[3] have been unable to demonstrate mu in hyaline membranes by histochemical methods, this does not surprise us, since we have found that epithelium of the respiratory bronchioles is muc negative, and that the only mucus secreting gl present are sparse subepithelial acini Very rec Gilmer and Hand[8] concluded from morphological stu that the membranes are endogenous, and, by application of two methods hitherto not used in the st of this disease, we ourselves have come to the s conclusion Our methods seem to reveal both the nat and source of the membranes

Using frozen sections of formalin-fixed material, applied the Lepehne Pickworth benzidine nitroprus peroxide technique[9] By this method the erythroc were stained an intense blue black as expected, but hyaline membrane took on a uniform rich royal b colour The occasional blue black red cell could be eas identified as an entirely distinct body in the membra It was further noted that the epithelium of the respirator bronchioles and alveolar ducts showed a rich royal bl granularity, and in some cases this granularity was intense that the epithelial cells were seen as a unifor royal-blue The intensity of this royal blue staining the membranes and epithelium was somewhat less material which had been in formol saline for 3-5 month

At this stage we realised that we were dealing wit either organic iron or peroxidase enzyme, or both We then found that previous treatment with 5% sodium cyanide, or 5% sodium azide, or steaming for 5 minute in each case reduced the intensity of the royal blu staining, but did not abolish it However, we noted al that lengthy treatment of frozen sections by these method abolished the staining reactions by removal of the membranes and granules From these observations ar

om the fact that the staining intensity was diminished ı material which had been fixed for a long time in rmol saline, we concluded that the reaction was due rtly to enzyme but mainly to organic iron

To test these conclusions we applied the NADI action to frozen sections by placing these in 1% alpha phthol (alcoholic) for 5 minutes and then for 5 minutes 1% aqueous dimethyl para phenylene diamine By is technique the hyaline membranes and granules in e respiratory bronchioles were stained a purplish blue the indophenol blue, the staining of the red blood-cells ing more intense but of the same colour Prior treat ent of the sections with cyanide, &c. was found to minish but not abolish the staining reaction

The lungs of several controls were examined by both chniques, and from these it was apparent that the tensity of the specifically staining granules in the spiratory bronchiolar epithelium was inversely pro rtional to the gestation age and that it was greater in ematures dying of hyaline membrane disease than in mparable prematures not having this condition owever, the intensity of the granularity was much less very premature infants (less than 1200 g) Further was apparent that the specific granularity of the ithelia of the respiratory bronchioles and alveolar cts increased with respiration since it was virtually sent in lungs atelectatic from birth and in those of llborn infants The œdema fluid in adult cases of rebral trauma and in cases of bulbar poliomyelitis was und to contain abundance of these specific granules enly scattered throughout the fluid and it was clearly ident that drying and condensation of such pulmonary dema fluid would lead to formation of a membrane hich would stain uniformly by the techniques used

It is very unlikely that these specific staining reactions the hyaline membranes are due to diffusion of material o the membrane In the first place the staining is o even for a diffusion phenomenon Secondly where uld this material come from except from the respiratory nchioles which we have shown to be laden with nules of the same staining reactions? Hæmolysis as use is also unlikely, because the reactions were found cases with no pulmonary hæmorrhage and because a case of hæmorrhagic pulmonary disease of the new rn, where hæmolysis was evident in the presence of t red cells the picture was patchy and uneven ally we have found that the two reactions work pletely and equally well in deep frozen unfixed lung ue from a case of hyaline membrane disease

It seems to us most likely that the common factor ponsible for the two reactions (Lepehne Pickworth d NADI) is the cellular respiratory enzyme system tochrome-oxidase/cytochrome C It is indeed possible at respiratory enzymes are produced in the granules hich we have demonstrated in the epithelia of the spiratory bronchioles and alveolar ducts and it is mpting to suppose that this enzyme system is an ive secretion of the epithelia An analogy may there o be drawn between infants developing hyaline embrane disease and the experimental rabbits of rber in that both probably suffer from an uncontrolled cretion of this enzyme system Further it is very obable that the actual hyaline membrane represents condensed and dried accumulation of this secretion, pecially as it is conceded that the only factor known modify the incidence and severity of this disease is gh humidity

We cannot at this stage be certain that the substance(s) ving rise to the reactions described here are cytochrome-idase/cytochrome-C since other metallic porphyrin otein complexes could be responsible for similar stochemical findings

Metabolic Factors and the Infectious Process

THE section of pathology met on April 26 under the chairmanship of Prof L P GARROD the president to hear Prof RENÉ DUBOS, of the Rockefeller Institute, New York discuss the Effects of Metabolic Factors on the Infectious Process

Professor Dubos described experiments by which the expectation of life of mice infected with tubercle bacilli and also with strains of staphylococci salmonella, and klebsiella could be shortened. He had found that the expectation decreased when animals were exposed to various stresses" before inoculation A number of different stresses had been used including the administration of thyroxine or dinitrophenol, in such doses as to inhibit the animal's normal weight gain, or of sodium citrate and α keto glutarate The simplest method however, was starvation for thirty-six hours before inoculation and this method had given the most striking results. The results after starvation could not be explained simply by calorie deprivation for low-calorie diets adequately varied in constitution, which reproduced the effects of starvation, did not decrease the animal's resistance moreover the effects were observed too soon and were too quickly cured for this to be likely Nor was it simply weight loss that produced the effect for mice fed on diets so low in protein that their normal weight gain was offset were normally resistant to infection Professor Dubos had also shown that the most effective way of lowering resistance was by starvation for forty eight hours before inoculation and that recovery was complete after forty-eight hours on the standard Sherman diet On the other hand when the mice were fed with a mixture containing adequate fat, carbohydrate minerals, and vitamins but with essential amino acids in place of protein the state of increased-susceptibility was indefinitely prolonged Normal resistance was not restored until a whole protein was added. Not all proteins were equally effective in this respect and of those tested casein was the best

The results could be explained either by increased susceptibility of the animals to the bacterial toxins or by more rapid and extensive bacterial growth It had been found that, after thirty-six hours of fasting mice were more sensitive to endotoxins from gram negative organisms and to the recently isolated tuberculous toxin so that the LD$_{50}$ was reduced to a half or a third of that for normal animals Starvation for forty-eight hours, followed by a diet low in protein would reduce the LD$_{50}$ to a tenth But these comparatively small effects could not explain the observed change in susceptibility

In other experiments bacteria were injected intravenously in mice and later estimated quantitatively in various organs—with remarkable results Two groups had been studied: one had the standard Sherman diet (group 1) and the other had a diet low in protein and was then starved for forty eight hours (group 2) Both groups were inoculated with a dose of 10^{8} Friedländer's bacillus (group III) and their organs examined quantitatively for bacteria ten hours later with the following results

	Spleen	Liver	Blood
Group 1	0 0 18	1 1 0	Sterile
Group 2	12–6000	10–50 000	+ +

Similar results were obtained with other organisms—e.g staphylococci—and using other forms of stress, such as increased carbohydrate intake or thyroxine administration

Professor Dubos concluded that the effect of malnutrition was to impair the local bactericidal powers of tissues possibly through depression of the reticulo-endothelial system It has been shown (Berry and Mitchell) that if the Krebs cycle was poisoned the animal's resistance was likewise depressed Therefore it seemed that the observed change in susceptibility might be explained by (*a*) lack of cellular glycogen, or (*b*) decreased glycogenolytic activity by the cell, or (*c*) lowered levels of polycarboxylic acid in the tissues All these effects led to impaired clearing-power of the reticulo endothelial system, decreased bactericidal power of the tissues, and decreased resistance to bacterial toxins Impaired antibody formation could not be cited, for mice had no natural immunity to Friedländer's bacillus

Summing up, Professor Dubos made three points (1) susceptibility to infection in mice can change rapidly as a result of various stresses, (2) the effect is rapid in onset, and rapidly reversible, and (3) the factors concerned seem to be independent of those taking part in the host's normal physiological processes

Prof A A Miles discussed the vascular phenomena during the earliest stages of infection He had found that the local reaction to the subcutaneous inoculation of organisms could be abolished by adrenaline, and that if this was done survival of the inoculum was enhanced tenfold The effect could be obtained only if adrenaline was injected locally within four hours of the bacterial inoculum Similar results were observed when the complement was inhibited by 'Liquoid' When the experiments were repeated using the vole bacillus, adrenaline was found to have little effect, but liquoid greatly enhanced survival in the local lesions By using histamine or a globulin permeability factor the local lesion was reduced in size to that of one produced by a tenth of the inoculum in untreated animals

Dr D A Long spoke on hormone balance in allergy and immunity He emphasised the importance of choosing a laboratory animal which showed similar immune and allergic reactions to man and which responded similarly to hormones, if the results were to be extended to man He described a series of experiments by which he had shown that the guineapig was a suitable animal He went on to show that significant variation in allergic response was obtained with several hormones Anti- and pro-diabetic factors exerted an effect, and significant desensitisation of tissues had been obtained with a recently isolated and quick acting thyroid derivative Sensitivity to tuberculin could be related inversely to blood sugar levels, and partial pancreatectomy prevented the increased response seen after treatment with thyroxine, which therefore acted through the islets of Langerhans He concluded that immunity was probably due to the balance between insulin and cortisone at any one time

Dr G G Meynell discussed the protective function of the gastro intestinal tract against infection He had found that *Salmonella typhimurium* was killed at pH2 in two to three minutes He had also shown that if the gastro intestinal flora in mice were modified by the administration of streptomycin, their resistance to an oral dose of *S typhimurium* was decreased, and also that the organisms given by mouth could be recovered from the large gut This type of effect might be important in man

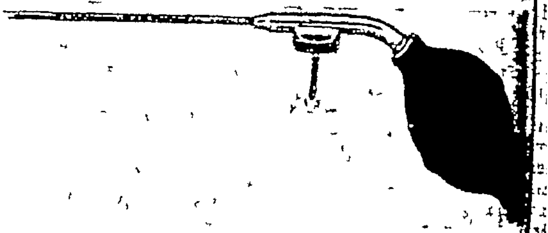
During the discussion, Dr Brian Lacey wondered whether sufficient attention had been paid to the genetic constitution, age, and sex of the mice used, and Dr A Felix, F R S, asked whether Professor Dubos's results were to be explained solely in terms of local cellular effects, or whether antibodies could account for some of them Professor Dubos felt that all the observed effects were probably mediated through a common channel, which facilitated both local tissue reactions and antibody

On the question of applying the results of ments to man, he said that no one knew better than he that mice and men were different, but justified the choice of a different animal when question to be answered by the experiment was sp and sufficiently limited

New Inventions

A MODIFIED THROAT SPRAY

In throat sprays used for spraying the throat bef endotracheal intubation or instrumentation, the b is joined to the nozzle by a flexible tube, with the r that the operator has to use both hands, and may the services of an assistant The throat spray illustr



here can be operated single-handed It is simple sturdy in construction, inexpensive, and effective T nozzle is long enough to be introduced between vocal cords for local preparation of the trachea. T Macintosh-type container keeps the volume of anæsthetic within safe limits and has the additi advantage of being unbreakable With a shorter noz the spray should also prove valuable in otolaryngology

The instrument can be obtained from Medical & Indust Equipment Ltd, for whose coöperation I am grateful.

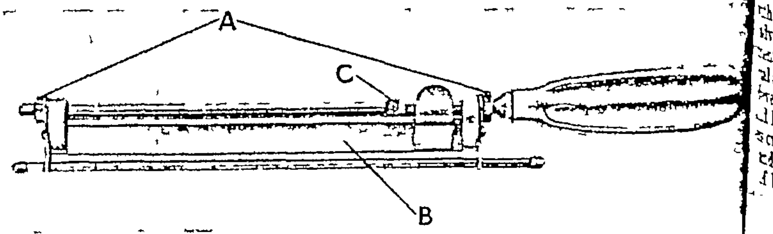
Mark Swerdlow

Manchester M.D, B SC Manc., F.F.A R C.S., D.A.

MODIFICATION OF HUMBY KNIFE

There have been several modifications of the orig Humby knife, with the aim of making it lighter *enabling the blade to be readily replaced and adj* In a new model, made at my suggestion by M Allen & Hanburys, these modifications have combined, and in this model the instrument need n dismantled to replace the blade Ease of sterilisation storage have also been considered

This new modified Humby knife is light and balanced Adjustment between the roller and the b from 0 01 mm to 1 0 mm is made by two kn collars (A) mounted on the back of the knife The bl



6¼ in long, is of the wafer-razor type and is lock securely in a leaf-spring holder (B) To fit a new bl it is only necessary to move a safety catch (C), open th leaf and insert the blade under the roller, and repla the safety catch

The knife without the blade can be sterilised b boiling, without risk of damage, and the blade sterili in the same manner as the standard interchangeab scalpel blades Since the blade can be fitted and remov quickly and easily, no protective cover is necessary f sterilisation or storage.

Reviews of Books

uroanatomical Basis for Clinical Neurology

TALMAGE L. PEELE, M.D., associate professor of anatomy in charge of neuroanatomy, Duke University School of Medicine New York and London McGraw Hill 1954 Pp 564 100s

MUCH has been said of the necessity for integrating ysiological and anatomical knowledge with subuent clinical training Most formal textbooks of atomy do, in fact, include paragraphs, usually in very ll print, devoted to applied anatomy Unhappily h excursions rarely succeed and it is often hard to cern the true links between form function, and ical disorder Dr Peele in this new textbook is very initely aware of the trefoil nature of this teaching blem and equipped with a practical training in earch neuro-anatomy and clinical neurology, he has ackled it in admirable fashion

After a short but adequate and well illustrated account the histological and embryological details of the nervous tem, he gives formal sections on descriptive anatomy of its ious components. In each section however there also pears comment on the physiological factors relating to the uctures described together with some of the more important hological changes to be expected and their clinical mani ations. Thus the account of the blood supply and ven ular system of the brain is followed by a short discussion he circulation of the cerebrospinal fluid a description of its mical and physical properties, and the clinical aspects of eased intracranial pressure Similarly the factual account he spinal cord is accompanied by physiological and clinical ail which though brief will at once inform and stimulate preclinical student In discussing recently acquired tomical knowledge Dr Peele maintains his standards nature and activity of the reticular formation are clearly cribed and recent electrophysiological work on the ebellum is succinctly presented. Some of this more con ersial evidence is perhaps offered a mite too firmly but teaching it is important to take up a reasonably definite itude. He is in any case to be congratulated on the healthy pticism he displays about the present evidence on the ppressor zones.

This admirable book is well illustrated and includes omprehensive bibliography

dern Trends in Ophthalmology

3rd series. Editor: ARNOLD SORSBY M.D., F.R.C.S London: Butterworth 1953 Pp 346 65s

Professor Sorsby is again to be congratulated on his rnational team of contributors, who give an admirable vey of knowledge which has not yet reached the tbooks. The book is arranged in sections dealing in n with the basic sciences on which ophthalmology s, advances in diagnostic procedures, clinical and erimental pathology clinical aspects in treatment, social aspects. Adequate space has been given to the st developments in anatomy physiology and patho- y and Professor Sorsby himself has contributed good pters on the nature of malformations, and on strepto- cin and the new antibiotics, as well as on the social pect of blindness. With Miss Mary Savory he also ites on cortisone and corticotrophin in diseases of e eye

ctions with Drug Therapy

HARRY L ALEXANDER M D emeritus professor of clinical medicine Washington University medical school Philadelphia and London W B Saunders. 1955 Pp 301 52s 6d

THE increased frequency of drug reactions in the past o decades has prompted Professor Alexander to compile s volume. He defines the reactions as lesions occurring only a small proportion of treated patients, differing om pharmacological effects and overdosage effects of e drugs and induced by therapeutic or subtherapeutic ounts

Only a few reaction patterns occur the main ones are matological manifestations, blood dyscrasias, serum sickness, shock, bronchial asthma, hepatitis, and polyarteritis nodosa. In the opening chapters of the book these patterns are described and their mechanism is discussed Controversial aspects of the subject are not fully discussed and this section is clearly not addressed to the specialist The general clinician may find the argument difficult to follow in places, and in many passages the syntax suggests overhasty revision. In the second part of the book many commonly used drugs and the reactions to which they give rise are described. Here the presentation is clear and informative and a coherent text replaces the catalogue common in works of this kind

Vitamins and Hormones

Advances in Research and Applications Vol XII Editors ROBERT S HARRIS professor of biochemistry of nutrition Massachusetts Institute of Technology Cambridge Mass; G F MARRIAN professor of medical chemistry University of Edinburgh; KENNETH V THIMANN professor of plant physiology Harvard University Cambridge Mass New York and London: Academic Press. 1954 Pp 303 $7.50

THE emphasis in this volume has been on vitamins, and consequently on nutrition; but three of the eight articles deal with hormones.

The first by John Hammond of Cambridge deals with the effects of light on hormone production and is concerned chiefly with seasonal changes, particularly those of reproduction which can be induced in warm blooded animals by modifying the illumination There is an interesting review by R B Bradbury and D E White (Western Australia) on œstrogens and related substances in plants, and one for practical men by F W Lorenz (California) on the effects of these œstrogenic hormones on the domestic fowl and their value in the poultry industry for fattening and other purposes. There are two papers on vitamin A—one by Saul H. Rubin and Elmer De Ritter from the Hoffmann La Roche laboratories, New Jersey dealing with the vitamin A requirements of animals, and the other by C Nieman and H J Klein Obbink of Amsterdam, dealing with the biochemistry and pathology of hypervitaminosis A . Both these papers are pertinent at the present time since the synthesis and large scale production of vitamin A has recently been effected by Hoffmann La Roche The authors give a valuable table summarising the dosages which have already proved toxic for man and the times for which they were administered Two English scientists, S K Kon and J W G Porter have contributed an account of that most complex but important subject the synthesis of vitamins in the ruminant: it now appears certain that the host and the micro-organisms in its rumen have established a nutritional symbiosis which is responsible for the provision of far more than the vitamins which the host requires. The article on the chemistry of vitamin B_{12} by Karl Folkers and Donald E. Wolf who are working in the Merck laboratories New Jersey is the most highly specialised and also the longest paper in the volume. The article by Charles S Davidson of Boston Massachusetts, on disturbances in nutrition relating to liver disease in man is a short and very readable account of current views on kwashiorkor alcoholic cirrhosis and other clinical disturbances in which the liver plays a prominent part

Doctors may be recommended to begin reading here; chemists, physiologists, and animal husbandmen will probably begin somewhere else in the volume but all may be recommended with confidence to begin.

A Handbook of Emergency Toxicology

A Guide for the Identification Diagnosis and Treatment of Poisoning SIDNEY KAYE B.S M SC associate professor of legal medicine Medical College of Virginia Springfield Ill Charles C Thomas Oxford: Blackwell Scientific Publications. 1954 Pp 303 42s

HE is a brave man who sets out to write an acceptable book on toxicology for the subject matter is about as inspiring as the contents of Bradshaw or a street directory Mr Kaye's great diligence shines out from the pages of his handbook but he has been no more successful than his predecessors in writing a best-seller

Upwards of 200 pages are occupied by a routine review of common poisons arranged alphabetically A telegraphic style is adopted this may be an advantage in a book designed for quick reference, but it inevitably makes this part of the text unreadable There is a table showing the names of the poisonous constituents of a large number of proprietary compounds —headache powders, weed killers, and the like Another table sets out the poisons contained in household articles—cosmetics, inks, matches, metal polish, and a score of the other perils that lie about us in our infancy It is difficult to imagine that anybody will get much help from the chapter on symptoms and signs to list 29 poisons and 15 diseases which may cause vomiting, purging, and abdominal pain does not suggest a very enlightened approach to toxicology, a few general principles would have been more valuable, especially if the subject could be correlated with physiology, pharmacology, and clinical medicine The author devotes only a paragraph to general considerations in this chapter, and the guidance here falls short A chapter on analysis provides a short survey of some of the chemical techniques of toxicology, but it is too meagre to interest the analytical chemist or the hospital biochemist In a book for students and practitioners, a competent essay on the collection of samples for expert analysis would be more valuable

Such books as this provide the best of all arguments for transferring the teaching of toxicology to departments of pharmacology, where the basic sciences are steadily ousting empiricism

Modern Trends in Psychosomatic Medicine

Editor DESMOND O'NEILL London Butterworth 1955 Pp 375 55s

PSYCHOSOMATIC medicine, though new in some of its aspects, is as old as medicine itself in others Some of the twenty articles in this fourteenth volume of the excellent *Modern Trends* series set out old and well-accepted views on the influence of the mind on the body, others offer less well-known and certainly less well-accepted ideas on a diversity of bodily, emotional, and psychiatric conditions The book contains most of the clinical evidence relating such disorders as thyrotoxicosis, ulcerative colitis, asthma, and skin diseases to psychological disturbances, and reviews the psychosomatic concept in medicine in general To the enthusiast it will offer a multitude of opinions confirming his belief that almost every illness is due to psychological stress In the sceptic it may provoke bewilderment and doubt that so much can be attributed with such confidence to such a cause, for though parts show a true and keenly scientific approach and parts are statistical, other chapters are mainly conjectural, and a few are almost frivolous The pleasantly classical and humanistic flavour of much of the writing is refreshing, and the references are copious and well chosen Dr O'Neill is to be congratulated on presenting such a full and varied picture of his subject, even if it may seem, perhaps inevitably, more one-sided than it should

Diagnostic Advances in Gastrointestinal Roentgenology

Selected Methods, with Clinical Evaluation ARTHUR J BENDICK, M D, director of radiology, Beth Israel Hospital, New York New York and London Grune & Stratton 1954 Pp 131 $6 00

IN the preface to this book the author states that "it is not intended for beginners but for radiologists of several years' experience, so situated that they cannot keep up with all the new techniques or the more modern interpretations of roentgen findings" Unfortunately it fails of this purpose, for it contains many inaccurate statements

Thus we are told that gravity does not play any appreciable part in the passage of barium from the œsophagus to the stomach, that the detection of neurological interference with swallowing is aided by demonstrating less distinct elevation of the hyoid bone on the films (but not how or under what circumstances), that the "club soda" technique in achalasia can be used as a method of deciding operability (but not how), and that amyl nitrate (not nitrite) is given to demonstrate the cardio œsophageal junction in achalasia We are told too "that the muscle of the diaphragm plays only a minor role in constricting the œsophagus at its lower end"

Th[illegible] not, on the whole, to be able to recommend a [illegible]ich a sound object

Antenatal and Postnatal Care (8th ed Lond J & A. Churchill 1955 Pp 672 37s 6d)—In p this edition of his reliable and senior textbook Prof F. Browne has had the collaboration of his son, Prof. J McClure Browne This family combination seems to worked well In including new work on the toxæmi pregnancy they draw attention to the work at the Wom Hospital, Sydney, Australia, where a determined campa to prevent eclampsia has resulted in a decline in inci from 1 in 400 in booked patients in 1946 and to 1 in 20,000 patients since, in the 1 failure, a ri blood-pressure had been overlooked The Brownes find t in every eclampsia patient there are one or more war signs which should lead at once to prophylactic treatment, their book does everything possible to ensure that th and other warning signs, in pregnancy and after, are missed

Alexander the Great and his Time (London Rock 1955 Pp 300 25s)—Dr Agnes Savill, well known as th editor of her husband's popular *System of Clinical Medi* has turned historian and here recounts the adventurous romantic story of Alexander the Great Alexander bec king of Macedon on the murder of his father, inheriting best equipped and trained army in the world At the age twenty he made himself master of Greece and began wonderful conquests marching from Macedon across t Hellespont to Egypt and from there through Persia to t upper reaches of the Indus in Hindu Kush When he d at the age of thirty three he had marched with his a nearly twenty two thousand miles often under unbeliev difficult conditions He fought innumerable battles, fre after a long forced march or a hurried climb up what enemy believed to be an unclimbable cliff or mount His weapons were surprise, swiftness of decision, imaginat foresight, ability to inspire and maintain the coöperati of his subordinates, and superb physical fitness and athl skill Dr Savill has written an interesting book. On left wondering whether she does not rebut too freely of the calumnies heaped on Alexander by some histor But if she tends to gild her lily, she leaves no doubt the reader's mind of the qualities that made Alexa great

Principles of Internal Medicine (2nd ed Lond H. K Lewis 1954 Pp 1790 £5 10s)—When the edition of this book by Dr T R Harrison and his coll was published in 1950, it was at once accepted as an auth tive textbook of American opinion The second e establishes it even more firmly as a standard work of ref The general arrangement is the same as before The third deals with general considerations and the rem considers the different systems of the body one by A new chapter on the general care of the patient giv useful review of nursing principles and the treatment symptoms in general The new edition is some 200 p longer than its predecessor, and with somewhat c print and some compression of space it contains a great more Chapter headings have gone and some of the illus tions have been much reduced in size The index has, great gain, been almost doubled in size The contribu now number 85, an advance of about 30 An important section of over 100 pages, which replaces the section weakness, is written by Dr R D Adams and his associ and includes an excellent and lucid account of the an states, depression, sleep disorders, fits, delirium, co and the psychoses

I was a Drug Addict (London Rider 1954 Pp. 15s)—Although Mr Leroy Street assures us that his acc is "uncoloured" the literary form evidently owes much to collaborator, Mr David Loth, who is a professional wri Fewer sentences such as "these homely objects were abo convey a new meaning to my specially alerted brain," fewer verbatim conversations would make the aut graphical statement seem more authentic As it sta however, it describes, in rather exaggerated language subjective experiences and the companionship which drug addict meets in his descent There is no obv improbability in all this, except for the happy ending w represents permanent recovery as the outcome of a fortu self directed plan for reducing the dose of morphine grad The work has social rather than medical or psychol interest

THE LANCET

LONDON SATURDAY MAY 14 1955

Orbital Leucotomy

STANDARD leucotomy, or lobotomy developed y **FREEMAN** and **WATTS** in which a large part of the refrontal areas is severed from the rest of the brain, as of late been carried out only in cases of long anding mental illness with severe behaviour dis der Apart from the unpredictability of its atomical results it commonly causes undesirable rsonality changes These changes, it was observed, re more likely to occur when the operation had en extensive and attempts were therefore made to ut it to a minimum Clinical observation of tients with frontal lobe injuries, as well as experi ental work, suggested that a regional factor was portant Several workers reported satisfactory sults from "lower quadrant" operations aimed at lating only the orbital part of the frontal lobes hese, like the standard leucotomy, were still blind ocedures lacking in precision With the increasing e of open operations various selective methods have en developed. One of the most interesting of these the undercutting of certain parts of the frontal rtex first proposed by **SCOVILLE**[1] who compared e effects of undercutting three cortical areas with ose of standard leucotomy The areas chosen were e superior surface of the frontal pole the orbital urface, and the medial surface of the cingulate gyrus e found that in schizophrenia and the affective ates undercutting the superior or the orbital surface ought about the same results as the standard eration, but with less personality defect. He garded undercutting of the orbital surface 'as e ideal operation for psychoneuroses and the milder ood disturbances because of the almost complete bsence of personality changes There was much o recommend the choice of that particular area for atients with otherwise intractable anxiety and epression

The importance of this area as part of the cerebral ubstrate of emotional integration is now generally ecognised **TOW** and **LEWIN**[2] described the results f undercutting the orbital surface in twenty patients ith various mental disorders who were subsequently followed up for two years. The effects were comparable with those of the standard operation, but the personality changes were less pronounced. Two reports on earlier pages of this issue appear to confirm the value of the method Dr **STRÖM OLSEN** and Mr **NORTHFIELD** have applied it to a group of patients with chronic neurotic tension states, in each of these patients, including one with pronounced paranoid ideas, depression was prominent More than half recovered from their symptoms and personality changes were slight Another group, suffering from long standing schizophrenia with personality deterioration, did less well Mr **KNIGHT** and Dr **TREDGOLD** report on a series of fifty two patients subjected to a slight modification of cortical under cutting Their results are almost as impressive as those of **STRÖM OLSEN** and **NORTHFIELD** They also found that improvement was most striking in patients with anxiety and depression Patients with hysterical symptoms did not respond favourably The two reports confirm the beneficial effect of orbital under cutting and the absence of severe postoperative personality changes, but it is difficult to compare the results in detail since these were differently assessed. **KNIGHT** and **TREDGOLD** eschew the term recovered" used by the other group of workers, but it can be assumed that the majority, if not all, of their "much improved" patients would have been classed among the "recovered" by **STRÖM OLSEN** and **NORTHFIELD** Evaluation and classification of therapeutic results is a serious problem in psychiatry, and communication between workers in the same field is often bedevilled by the pitfalls of semantics

The fact that an operation as limited as orbital undercutting can produce a substantial and often dramatic change in the mental state seems at first to contradict the view held by earlier workers that the degree of improvement depends chiefly on the amount of brain substance isolated **MEYER** and **BECK**[3] suggest that, though the extent of the operation is important regional localisation of the cut within the frontal lobe also influences the effects They point out that some very limited regional cuts may in fact, by severing the thalamofrontal projection, isolate large areas of cortex The question, therefore whether the frontal lobe functions by mosaic or mass action has still not been finally answered In their experience, the extent of the cut, wherever localised is correlated with improvement But various types of improvement follow surgical interference with frontal lobe function one is the complete disappearance of symptoms, especially of depression, immediately after the operation almost any operation on the frontal lobe however limited has sometimes resulted in this dramatic change In such instances at any rate, improvement or even recovery does not seem to have been bought at the price of a severe personality change, so obvious in other patients The results of cortical undercutting show that notoriously reversible symptoms, such as depression and anxiety, can be removed sometimes by a very limited operation—an effect which, though profound, is clearly unrelated to the personality change

[3] Meyer, A., Beck, E. Prefrontal Leucotomy and Related Operations Edinburgh, 1954

In what type of patient can one expect such a distinct improvement ? Here we are still in the dark STRÖM-OLSEN and NORTHFIELD consider that neuropathology may some day provide the answer Some workers believe that it will eventually be possible to produce lesions to suit every condition and every patient The fact that the results of a precise and limited operation, such as orbital undercutting, are still inconstant, suggests that the effect does not depend only on the extent and localisation of the lesion The patients' personality—the sum total of his response patterns, innate and acquired—must be of considerable importance Only when we know more about the reactions of the personality to sudden alterations in the emotional charges shall we be able to predict the effects of surgical treatment in individual cases The psychiatrists, it is true, have been aware of this, and have generally accepted that in well-integrated personalities the likelihood of undesirable postoperative behaviour features, even after extensive operations, is small, but beyond this we know very little Naturally, clinicians are more interested in their successes, especially when a method has still to be established But the time comes when careful and systematic study of failures and partial failures is at least as important as that of successes This is particularly true in the present stage of the surgical treatment of mental disorders Such studies would also act as a wholesome corrective to the danger of a reversal to "atomistic" concepts of cerebral function The effects of localised operations on mental states have contributed to a revival of concepts reminiscent of those so persistently criticised by HUGHLINGS JACKSON, and a language has crept back into medical writings which not so long ago seemed almost extinct What would JACKSON have thought of the "intellectual pathways" referred to by KNIGHT and TREDGOLD ? The passage from LE GROS CLARK cited by these workers, and MEYER and BECK's[3] recent warning against too atomistic an interpretation of the effects of brain operations, show that at least some of those most familiar with cerebral structure and functions are opposed to a return to the old-fashioned rigid localisation of functions Only by taking into consideration the undamaged parts of the brain and the reactions of the whole personality shall we reach a fuller understanding of the scope and limitations of the surgical treatment of mental disorders

Estimation of Blood-loss

THE most important cause of shock after surgical or accidental injury is loss of blood into and from the damaged tissues, or of plasma in cases of burns and scalds, or of crushing Such shock usually responds to the rapid replacement of the lost fluid, but measurement of the amount lost, even at operation, is not easy

Estimates based on impressions during the operation are usually too low, even when reinforced by collection of the swabs, towels, and gowns Surgeons who have not submitted themselves to the discipline of direct measurement of blood-loss usually find it hard to believe the figures obtained in this way Som for example, when the operation is for arance of viscera in the pelvis or of a large block of organs in the upper abdomen—estimates based on impressions are of hardly any value, and when, in addition, the operation lasts many hours and is accompanied by transfusion to replace lost blood, direct measurement is especially necessary To be useful the method of direct measurement must provide an accurate answer shortly after the operation has ended Probably the simplest way is to wash out all the swabs, towels, gowns, and instruments in a known volume of water, to which is added the contents of the suction bottle The hæmoglobin level of this fluid is then measured either directly[1] or after conversion to acid hæmatin[2,3] This, together with the hæmoglobin level of the patient's blood before and immediately after operation, gives a fairly accurate guide to the volume of blood lost. PAQUIN et al[4] have devised a method suitable for cases in which blood or other intravenous fluids are being administered The difference between preoperative and postoperative weight is corrected on the one hand for additions (including dressings and transfused blood or other fluids), and on the other hand for depletion by bleedings, estimated insensible water-loss, resected tissue, and excreted urine and other lost body-fluids As a check they also measure blood-loss directly,[5] by weighing the towels, swabs gowns, and suction-fluid They have found close agreement between the results by these two methods, even for operations lasting ten hours with a blood-loss of over 4 litres But they point out that serious errors may arise from the accumulation of shed blood in "dead spaces"—for example, the pelvis—and from excretion of urine or, in operations on the urinary tract, from contamination of blood with urine Furthermore the method of PAQUIN et al cannot be expected to give really reliable results until we know more about the possibly wide variation in insensible water-loss during different types of anæsthesia and they themselves emphasise that their method should be combined with clinical examination before deciding on treatment Fortunately operations lasting for more than three hours are rare, and the amount of blood lost at operation seldom exceeds 2 litres

Measurement of blood or plasma lost by accidental injury is even less easy Theoretically such loss would be best measured by estimating the amount of blood remaining in the circulation and subtracting this from the normal volume, which, as GIBSON and EVANS[6] showed, is closely related to body weight But this approach is so studded with pitfalls that others have been tried NOBLF and GREGERSEN[7] found that in civilian injuries blood loss depended largely on the extent of muscle damage and the number of fractures, and GRANT and REEVE[8] showed that in limb injuries the volume of damaged tissue was a good guide to the volume of blood lost Mr RUSCOE CLARKE and his colleagues[9] have measured the increase in the volume of injured limbs nd also the red blood cell volume, and have stablished that estimates of blood loss based on hese two measurements agree closely. Their findings confirm the close relation of blood loss to muscle njury, which is particularly severe in fractures nvolving the shaft of the femur or the pelvis. Nevertheless, although the bleeding associated with such njuries is commonly underestimated, there is still nsufficient evidence to justify the very large transfusions of blood recommended by PRENTICE et al.[10] Early surgical treatment should be combined with rapid transfusion of enough blood to maintain the blood pressure within normal limits. The anæmia which follows severe injury presumably reflects the general post-traumatic protein katabolism, and should not be treated prophylactically by the administration of blood in excess of that needed to restore circulatory efficiency.

The Mystery of Dental Caries

DECAYED teeth have caused the human race suffering and unhappiness for several thousand years. In ancient times dental caries was associated with the idea of worms in or around the teeth, and this notion persists in the primitive cultures of today. It seems that a certain JAQUES HOUILLIER (1498–1562) first cast doubt on the existence of dental worms, but that did not prevent GOTTFRIED SCHULZ, who lived at about the same period, from declaring that the application of gastric juice from a pig would expel worms—some even as large as an earthworm—from a decayed tooth.[11] GALEN believed that dental caries was produced by an abnormal condition of the blood which affected the internal structure of the tooth, and recent work gives some support to this hypothesis. The suggestion that micro-organisms might be responsible for caries was first put forward by LEBER and ROTTENSTEIN in 1867.[12] A few years later, MILLER,[13] working in KOCH's laboratory in Berlin, found that micro-organisms obtained from carious dentine produced lactic acid when cultured in the presence of sugar or starch, and he formulated the "chemico-parasitic" theory of dental caries. In 1925 BUNTING and PALMERLEE identified the commonest acid-producing organism in the mouth as *Lactobacillus acidophilus*.

The chemicoparasitic theory, together with the belief that dental caries is associated with the consumption of small molecule carbohydrates that are readily fermented, has been widely accepted for some fifty years. There is now much evidence supporting the theory, including the increased incidence of caries among Eskimos when refined carbohydrate foods were added to their normal diet.[14] Investigations during and after the wars of 1914–18 and 1939–45 also seemed to suggest that when sugar was rationed and other highly refined carbohydrates were scarce the incidence of dental decay in children dropped sharply, whereas it rose again sharply in the post-war years. More recently many research workers have come to believe that the incidence of caries is influenced by other factors—the structure of the tooth, conditions affecting the metabolism of the body, and the ingestion of fluorides in drinking water. Some workers now believe that caries is initiated by proteolysis of the organic constituents of the enamel and that decalcification is secondary.

A report just issued by the Medical Research Council[15] throws considerable doubt on the idea that caries in children is caused, at least partly, by excess of sugar in the diet. This report describes trials in London, Liverpool, and Sheffield on the effects of adding extra sugar to the diet of children in residential homes. The incidence and spread of dental decay in groups of children aged 2–14 years, was first observed for a year, during which the children received their normal diet containing liberal amounts of milk, fresh fruit, and vegetables, and, in most cases, supplements of cod-liver oil and orange juice. The children were then divided into two groups: one continued to receive the normal diet, while the other received additional white sugar. The dental condition of this group was compared with that of the controls at the end of 1, $1^{1}/_{2}$, and 2 years. Since work by OSBORN et al.[16] had suggested that unrefined sugar might contain some factor which tended to protect the teeth from attack by caries, raw sugar was included in the diets of some of the test children. The diets were arranged so that the control groups received 11 oz. of sugar a week, while the test groups received just over 22 oz. of white sugar or about $21^{1}/_{2}$ oz. of raw sugar. The results were somewhat unexpected. Despite the relatively large differences between the amounts of sugar given to the control and to the test groups there was no significant difference in the incidence or the spread of dental caries during the 2 years. There were some anomalous findings—for instance, some of the children who received extra white sugar actually had a significantly smaller incidence of caries than the controls—but these findings showed no consistency when the results were surveyed as a whole. There was no evidence that sugar affects the two dentitions differently. As far as could be ascertained, unrefined sugar does not contain a caries-inhibiting factor.

None of the children in the trial groups received more than about 4 oz. of sweets a week, and the report does not prove or even suggest that unlimited sweets are harmless. Mr. E. B. DOWSETT, in his presidential address to the British Dental Association in 1951, suggested that sweet-eating by children should be controlled.[17] In his view sweets made from glucose—as many now are—are more dangerous to the teeth than those made from sucrose. The problem of caries is undoubtedly in the broadest sense dietetic. But what aspect of the diet is at fault? Is there a local and external effect on the tooth, or is it systemic and internal? These possibilities are not mutually exclusive, and if the latest report has done no more than eliminate another hypothesis, that at least brings us one stage nearer the solution.

Annotations

REGULATION OF CARDIAC PERFORMANCE

Starling's classical work on the isolated dog heart demonstrated that the strength of its contraction, and therefore stroke output, was determined by diastolic ventricular volume This accorded with expectation, since the strength of contraction of striated muscle is, within physiological limits, determined by the initial length of its fibres In recent years Starling's law has been much discussed in relation to adaptation of the heart to disease, and an exceptionally well documented symposium on this important topic has now been published [1–9]

Three different sets of observations must be considered (1) on the isolated heart preparation where reflex, nervous, and hormonal influences are excluded, (2) on healthy intact mammals, and (3) on patients with heart disease

In the isolated heart the validity of the Starling principle is accepted,[5] but its exact mechanism is still disputed [6] "Venous return" is often said to determine cardiac output, but in any balanced state of the circulation venous return must be the same as the cardiac output Increased diastolic filling of the heart is much more likely to result from increased venous pressure, and this can occur physiologically by contraction of the spongework of venules and other small peripheral vessels pushing more blood towards the centre Guyton [3] has elaborated the conception of "mean circulatory filling pressure," which is the external squeeze of vessels on their blood content with flow factors eliminated This can be measured experimentally during induced temporary ventricular fibrillation, after which rhythmic cardiac contractions are re started by electric shocks As might be imagined, this "static" filling pressure rises with increasing volumes of blood in the circulation Though most of Starling's data showed a correlation between venous filling pressure and cardiac output, Starling himself appreciated that the filling of the heart might sometimes be greatly increased by very small pressure changes Katz,[10] using Wiggers's methods of accurate optical recording, showed that changes in cardiac output paralleled end-diastolic ventricular pressure It is, of course, better to estimate cardiac performance as *work* rather than simply as *output* Sarnoff,[2] who has re-studied the whole matter, has shown a linear correlation between venous filling pressure and *right* ventricular work, and when the left ventricle was loaded by increasing aortic resistance, pressure rose in parallel in the *left* atrium but not in the right Homolateral correlation is thus of the greatest importance For any given filling pressure the work of individual hearts could be increased by adrenaline or decreased by experimental restriction of coronary flow [2]

In intact animals and man the situation is more complex, since the heart is innervated and is exposed to varying amounts of endogenous adrenaline and other influences which may counteract the influence of changes in venous filling pressure End-diastolic volume and pressure may not always correspond if muscle tone can alter [1] While McMichael and Sharpey-Schafer [11] showed a significant general correlation between cardiac output and venous filling pressure in man, Warren et al [12] emphasised the exceptions to this rule Gregg et al[4] have found in the whole dog a general correlation between cardiac output and filling pressure when raised by intravenous infusion, but the correlation was not clear at lower rates of *infusion* Gauer [7] demonstrated close correlation between diminishing heart volume and stroke output in monkeys subjected to centrifugation Hamilton [9] reminds us that in many experiments with isolated animal hearts the outputs are artificially set much lower than the expected normal for the particular animal; Starling's law *might* be particularly easy to demonstrate under these conditions Richards [8] calls attention to the Swedish radiographic studies of heart volume, which show clearly that in exercise the heart increases in size only very slightly The increased output of effort is certainly brought about by increased rate and increased emptying of the ventricles—increased emptying has been of special interest since it was realised that under resting conditions the ventricles almost certainly do not empty completely and contain some residual blood at the end of systole

In patients with heart failure due to intrinsic heart disease the output tends to be relatively fixed, dropping to subnormal levels in the more advanced stages Heart rate in failure also tends to settle round 100 a minute Such hearts seem, like the kidney in advanced nephritis, to have lost their flexibility of response With this loss of fine adjustment, Starling's law may be the last resource of adaptation to pathological conditions In failing hearts the common absence of increase in cardiac output during exercise, despite a rising venous filling pressure, and other observations led McMichael and Sharpey Schafer [13] to the hypothesis that the failing heart behaves as though it were no longer responding normally to increases in venous pressure, such increases could even be accompanied by a falling cardiac output, and, conversely, lowering of venous pressure by venesection could be followed by improvement in cardiac output These observations may have to be considered in a new light, for Sarnoff [2] has pointed out that *decreasing stroke work at high filling pressure* is attributable to regurgitation through the atrioventricular valves The studies of Korner and Shillingford [14] show that some tricuspid incompetence is often present in heart failure The extent of this incompetence and its part in producing the congestive features of heart failure have not yet been fully appreciated

POLIOMYELITIS REVIEWED

WITHOUT doubt the great advances in our knowledge of poliomyelitis in the last few years began with the discovery by Enders, Weller, and Robbins [15] in 1949 that poliomyelitis viruses *could readily* be grown in tissue-cultures—a discovery which won them the Nobel prize in physiology and medicine for 1954 Thereafter our knowledge of epidemiology, pathogenesis, and prevention expanded at a great rate, and the new ground explored has lately been reviewed in a World Health Organisation *monograph* [16] In this Enders himself gives a beautifully clear exposition of tissue-culture techniques as applied to poliomyelitis, and Rhodes, Wood, and Duncan illustrate the application of these techniques in laboratory diagnosis Gard writes about the virus itself—*Poliovirus hominis* and the related *P muris* to use the correct terminology The new tissue-culture techniques have been applied first to urgent practical problems, and most of our theoretical knowledge of the virus is still based on earlier studies of infected nervous tissue, in which the virus may represent only a

millionth to ten millionths of 1% of the tissue It is therefore important to re-examine the properties of the virus grown in the more satisfactory milieu of tissue culture now available; to take only one point it is vital for vaccine production to know the resistance of the virus to different forms of inactivation Methods of inactivating virus on the skin are scarcely of less interest, since there is still a possibility that virus on the skin may be implanted by injections and on this matter Gard says "It can only be stated that, as a means of removing or inactivating virus on the skin the use of soap detergents, ether ether alcohol, or chloramine is nothing but a symbolic ritual only iodine might be expected to serve the purpose

Hammon describes the first stage in the striking progress in protection—passive immunisation with gamma-globulin The first large-scale trials in 1951 and 1952 showed that gamma globulin gave some temporary protection against paralytic poliomyelitis, and later work has demonstrated that the all important subclinical infections were not prevented. But mass administration of gamma globulin during epidemics has been disappointing and its use for prophylaxis of contacts cannot now be recommended for the first detected case in a family is seldom the first to be infected Hammon suggests that gamma globulin may be most useful in dealing with outbreaks of poliomyelitis in summer camps and boarding-schools. It is clear however that active immunisation is the main hope in preventing poliomyelitis, and in the monograph this subject falls to Sabin and Koprowski Sabin discusses immunity as a result of natural infection of man or experimental infection of animals with special reference to vaccination, and he is much concerned with variations in virus virulence Tissue-culture methods allow the detection of naturally occurring viruses of low virulence, and Sabin s important laboratory experiments have segregated avirulent virus variants which might later be used to immunise man. As we pointed out in a leading article last month[17] both Sabin and Koprowski believe that live avirulent poliomyelitis virus will prove best in the end; and this view may well find wider support when the difficulties that are now besetting the immunisation programme in the United States have been fully investigated Sabin and Koprowski have made considerable advances both in preparing avirulent variants from all three antigenic varieties of virus and in testing some of them in man There are many difficulties ahead in this field, but there is no reason to believe that they cannot be overcome in the next few years On p 1018 we report some of Sabin s latest findings which he described to a meeting of the Association of American Physicians last week

Our outlook on the epidemiology of poliomyelitis has also undergone some sharp changes of late, and these are discussed in the monograph by Paul Gear and Freyche and Nelson Poliomyelitis is world wide and in nearly all countries paralytic cases have become commoner and the disease has attacked older people The virus has spread widely however in underdeveloped countries where the disease has the characteristics of ' infantile paralysis —that is paralytic cases are less common in adults and are largely confined to infants widespread subclinical infections in infancy protecting against paralytic disease in adult life Similarly the first recorded epidemics in Scandinavia North America Australia and New Zealand fifty to seventy years ago were all infantile paralysis. The sparing of adults suggests that they were protected by previous subclinical infection, and it need not be assumed that this was a new disease The changed characteristics of poliomyelitis have in fact been created by our changed hygienic habits Poliomyelitis is today under pressure to spread from underdeveloped areas into a susceptible population and if the inter-epidemic period is long the risk of a severe epidemic increases annually One of the most graphic examples of this is the Hudson Bay epidemic in 1948–49 when 60% of the Eskimoes had paralytic disease, all age-groups were involved the lowest clinical attack rate being in the infants Gear mentions another fact which brings home the changing pattern of poliomyelitis in Nyasaland and Southern Rhodesia paralytic poliomyelitis is today one of the most serious hazards facing newly arrived adult European settlers. Discussing public health measures, Payne points to the anomaly that so far as poliomyelitis is concerned hygienic measures may have done more harm than good He suggests that early in an outbreak, or with inter-epidemic cases, the application of hygienic measures may prevent an epidemic from starting once it has started the large number of sublinical infections makes further steps of this kind valueless

PANCREATITIS

MODERN treatment has greatly changed the clinical course of acute pancreatitis as Kirby et al.[1] have shown by comparing cases admitted to the Hospital of the University of Pennsylvania before 1946 with those admitted in subsequent years Of 80 patients in the twenty five years up to 1946 23 (29%) died the majority from vascular collapse shortly after the illness began in 1946–53 110 patients were treated with 21 deaths (19%) Deaths in this second group took place later only 3 (14%) of the 21 deaths took place in the first week of the illness compared with 20 (90%) of the 23 in the earlier group The manner of death has also apparently changed Secondary hæmorrhage which was not observed before 1946 accounted for 11 deaths in the second group and in this group of those patients with hæmorrhagic pancreatitis who survived about a quarter bled either from an abdominal wound or into the alimentary tract Possibly antibiotic therapy has reduced the early toxic effects due to infection, so patients survive long enough for the erosive pancreatic enzymes to damage vessel walls and thus precipitate secondary hæmorrhage; Kirby et al. suggest that this complication may be prevented by proper drainage to encourage the escape of the enzymes.

The most severe form of acute pancreatitis was found after operations involving the pancreas There were 14 such cases with 8 deaths 7 from hæmorrhage In 6 of these 14 cases the pancreatitis followed subtotal gastrectomy in 5 subtotal pancreatectomy in 2 simple biopsy associated with cholecystectomy and in 1 colectomy for a growth adherent to the pancreas Obstruction of the pancreatic ducts is known to be a potent factor in precipitating pancreatitis[2] which for this reason is sometimes found in conjunction with carcinoma It is therefore not difficult to understand why pancreatitis follows operations such as gastrectomy or *pancreatectomy*, that may cause trauma to the pancreatic ducts But this does not explain all cases Millbourn[3] has drawn attention to the possibility of interference with the blood supply to the pancreas by damage to the superior and inferior pancreatico duodenal arteries but Warren[4] points out that the blood-supply is so generous that ligation of one artery alone would be unlikely to cause trouble Pancreatitis has arisen as a late complication of partial gastrectomy, through stagnation in the afferent loop and suggested causes include spasm of the sphincter of Oddi and sludging of pancreatic secretions within the ducts as a result of medication and dehydration[5]

Injury *to the ducts* is the most important cause of postoperative pancreatitis not only because it is probably the commonest but also because it should be treatable—if not avoidable In Warren's [4] 7 cases of pancreatitis following partial or total gastric resection, 6 of the patients died with pancreatic necrosis In 4 of these a penetrating duodenal ulcer was reported, in any of these 4 cases a duct may have been damaged, while in a 5th carcinoma of the stomach may have involved the pancreas The pancreatic duct, the accessory pancreatic duct, or both, were damaged at operation for duodenal ulcer on 6 other patients, 3 were spared *pancreatic obstruction by the development of a fistula*, which healed subsequently or was successfully implanted into the intestine, and in 3 the ducts were reimplanted at the outset, all survived and pancreatitis did not ensue It is not easy to observe either of these ducts lying in inflammatory tissue near the base of a duodenal ulcer, owing to their smallness it is still less easy to reimplant them when they are seen, unless they have been dilated by long continued obstruction In this form of obstruction there may be a place for Duval's [6] ingenious technique for curing chronic relapsing pancreatitis [7] This condition is commonly thought to be due to obstruction at the sphincter of Oddi inducing biliary reflux into pancreas, but Duval doubts this and, believing that pancreatitis is caused solely by the obstruction and that biliary reflux is immaterial, he suggests that the pancreas be drained through its tail by transecting and implanting this into the open end of a Roux-en-Y jejunal loop He has successfully treated 2 patients in this way

DIAPHRAGMATIC RUPTURE

THE diagnosis of traumatic hernia due to non penetrating injury is easily overlooked Most commonly the patient has received a crushing injury to the abdomen, so attention is directed more to possible visceral damage than to the abdominal parietes and chest Of the 7 cases seen by Evans and Simpson [8] 4 had fractures of the pelvis In the case reported by Dr Hamdi and Dr Sturdy elsewhere in this issue the patient appeared to have only a head injury, but while anæsthesia was being induced for reduction of a depressed fracture herniation took place through a diaphragm weakened by injury They agree with Evans and Simpson that a sudden explosive rise in intra-abdominal pressure, due to straining under the anæsthetic, can precipitate herniation This two stage mechanism—diaphragmatic trauma followed by herniation due to a momentary rise of pressure from below—can lead to further diagnostic difficulty since the two events may be separated by a considerable interval In 2 patients seen by Evans and Simpson six months and two years elapsed after the injury before the onset of symptoms, which in 1 case started quite suddenly while the patient was lifting heavy weights After such an interval the original injury may have been forgotten, and there may be no tell-tale scars to recall it Coincidental rupture of abdominal viscera is uncommon, and acute symptoms usually arise from displacement of lungs on the one hand and strangulation of abdominal viscera on the other In the case reported by Mr Sinha, also in this issue, the spleen was ruptured, but bleeding from it began only at emergency thoracotomy for reduction of the hernia Often, too, there is no pain referred to the shoulder, perhaps because the phrenic peritoneum is insufficiently irritated by a simple tear

Accordingly the diagnosis may be extremely difficult In a case lately investigated by a coroner [9] a young woman had received injuries to her face, body, and hip in a car crash After six days in hospital she was discharged, but returned almost immediately with internal hæmorrhage At laparotomy this was found to be due to recent rupture of the splenic vessels, the spleen itself was intact, lying within the abdomen, while stomach and colon had passed into the chest through a hernia in the diaphragm Radiography had revealed a diaphragmatic hernia which was regarded as congenital, and from the necropsy appearances it was concluded that the hernia was of long standing and probably congenital This may be another example of the double mechanism of a faulty diaphragm resulting later in expulsion of viscera into the chest

UNIVERSITY AND TOWN

FOR three days last month the University of Sheffie opened its doors to the people of the town Almost eve department in every faculty had prepared demonstratio illustrating the work they were doing In the faculty medicine, the department of medicine demonstrat the incidence of the killing diseases in a remarka cheerful way, and they allowed visitors to estimate th capacity of their lungs with a spirometer The departme of therapeutics and pharmacology showed some isoto techniques for measuring blood volume, and every could have an electrocardiogram while they wait Blood-transfusion work was vividly illustrated by th department of pathology, and the department of surgery had demonstrations dealing effectively with septic han arterial disease, and gastric acidity In the departme of obstetrics and gynæcology, the cycle of life, throu fertilisation, conception, and birth, was portrayed b *models and diagrams*

MEDICAL ASPECTS OF NUCLEAR RADIATON

THE membership of the committee on the medic *aspects of nuclear radiation* which, *as the Prime Minist* announced on March 29,[1] the Government invited th Medical Research Council to form, has now be announced The chairman is Sir Harold Himswort F R C P, F R S, secretary of the council, and the oth members are

Sir Ernest Rock Carling, F.R C S, F.R C P, consult adviser, Ministries of Health and Home Office (Civil Defen and member of the health policy committee of the Ato Energy Authority, Sir John Cockcroft, F.R S, director, Ato Energy Research Establishment, Prof Alexander Hadd M D, director, Chester Beatty Research Institute, J F Loutit, D M, *director*, M R C *Radiobiological* Research Un Kenneth Mather, D SC, F.R S, professor of genetics, Bir ingham University, W V Mayneord, D SC, professor physics applied to medicine, London University, P Medawar, D SC, F.R.S professor of zoology and compar anatomy, University College, London, J S Mitchell, M F.R S, professor of radiotherapeutics, Cambridge University L S Penrose, M.D, F.R S, Galton professor of eugen University College, London, Sir Edward Salisbury, D F R S, director, Royal Botanic Gardens, F G Spear, M deputy director, Strangeways Research Laboratory, Ca bridge, J R Squire, F.R C.P, professor of experiment pathology, Birmingham University, C H Waddingto SC D, F.R S, *professor of* animal genetics, Edinburgh U versity, Sir Lionel Whitby, F R.C.P, regius professor physic, Cambridge University, and B W Windeyer, F.R.C professor of radiology (therapeutic), London University

LEADERSHIP IN CARDIOLOGY*

The Charles Laubry Lecture

Sir JOHN PARKINSON

M.D Lond LL.D Glasg D.Sc N U I F.R C P
Hon. F.R C.P E Hon F.A C.P

In this lecture I am allowed to voice what is in my nd and memory In my mind is the realisation that e progress of cardiology has been mainly due to a ccession of individuals who proved to be leaders in ought in action and notably in discovery In my mory is the state of medicine, including cardiology en I began as a young student fifty years ago and the nsformation that has since taken place I propose to ak on three separate subjects first of those early ys and of that great leader James Mackenzie secondly specialism and the training of the cardiologist and rdly on French cardiology and the leadership of ofessor Laubry

Days Gone By

May I look back at medicine as I found it in my own ele at the London Hospital ? The study of the basic ences was limited to two years of inorganic chemistry ysics, and biology Then followed two years of atomy happily under Arthur Keith while physi gy was too largely a system of conflicting hypotheses, ough not for my own teacher Leonard Hill. All this ing over it was then our lot to live for as many hours possible with the sick in the wards and outpatient ics, learning by precept and practice what was ong with them and what to do for them We learned ly what our teachers knew except for what was in ir textbooks, the most popular of which was Osler's had no research consciousness though we were forced be clinically conscious In medicine our dozen teachers re equally chiefs ; but, looking back, how unalike their attitudes and talents ! Outstanding was Henry ad, an inspiring teacher but admittedly odd in having earch on the brain and even submitting to experi ntal operations on his own nerves Otherwise research d no place in the wards it was none of our business e were busy learning from our elders and there was a de variety of approach a wealth of practical experience those who moulded us One teacher one professor is ver enough the more the better—and often the rier Among them was that fountain of clinical sdom, Sir Robert Hutchison who is still with us and o prayed From inability to let well alone from much zeal for the new and contempt for what is old ; om putting knowledge before wisdom science before art, verness before common sense from treating patients cases ; and from making the cure of the disease re grievous than the endurance of the same : Good rd, deliver us'

During my medical apprenticeship our clinical practice s mostly empirical and we were not bothered by hniques As a clinical clerk I did use the first sphyg manometer in the hospital and a thin X ray film uld drift into the ward though it might show little yond the fingermarks of the radiographer There was n no separate science of psychology but patients were ted and treated as kindly as today though with less derstanding for the state of mind of the sick was not lised. Sex did not exist as a subject to be taken into ount by all doctors I had read Oliver Wendell Holmes however and he said ' The sound of a kiss is not so loud as that of a cannon but its echo lasts a great deal longer ' There were two kinds of heart disease, valvular and non valvular and we were satisfied Digitalis was given for heart failure in the wards but forbidden to outpatients Antibiotics were scarcely on the horizon and infections ran their course Many physicians had lost faith in therapeutics and patients were pacified with traditional remedies culled from the hospital pharmacopœia

In those last fifty years, medical practice has become more rational while advance by experiment has largely replaced advance by observation yet there is still ample scope in clinical science for patient observation I have been impressed by the way that the science of mind, psychology has gradually permeated practical medicine. Doctors more often and more exactly try to realise in their own minds the position and feelings of their patients. This studied humanism has largely taken the place of what was called the art of medicine Indeed today we may speak more simply and truly of the science of medicine It has been said that he is the best physician who inspires hope, but too often he brought ' no other medicine but only hope no material benefit Comparing the past with the present it is surely in *treatment* that advances of the greatest magnitude have been made The medical profession is greatly strengthened by the good will and moral support of the community and nothing has elevated medicine in public esteem more than the spectacular progress in medical and surgical treatment in recent years.

Men and Heroes

How then has medicine and with it cardiology, grown ? It is surely a story of men It is biography It is the life and achievement of a succession of men and women—a few of them geniuses many talented and a host with fewer gifts but determined to use them well Thus in a volume like Herrick's *Short History of Cardiology* we read a story of persons and their ideas and achievements rather than a summary of theoretical and factual progress.

In our boyhood and youth we all had our heroes bright and shining maybe historical or fictitious or martial but scarcely political and not at that time medical. As we emerged from boyhood and came to the study of Medicine this hero worship was still strong in us persisting through our medical training ; and many of our teachers became and remain our heroes You will agree that this faculty of admiration hero worship can and often does persist and that it still exerts a power in our lives It has truly been said that we are a part of all that we have met

People vary a great deal in the way they allow others to influence them Many are self sufficient sure of themselves independent Incidentally it has always been a surprise to me that Americans, whom the world regards as particularly independent and insubmissive to authority should be so devoted to their heroes—national social and medical Despite their inveterate fondness for something new and their urge to pursue the impossible they are catholic in their search for truth and love of learning Nowhere have the famous physicians of the past and of every country been held in greater honour than in the United States

Sir James Mackenzie

May I now remind you of the life and work of James Mackenzie the centenary of whose birth occurred last year ? At the age of 25 he joined a busy general practice in Burnley a Lancashire industrial town where, for twenty-eight years he practised medicine midwifery and some surgery It was under these conditions seemingly so unfavourable for such work, that the greater part of his original observations and researches was made Up to this time neither he himself nor others

---

rom the Charles Laubry lecture delivered at the 2nd International Congress of Cardiology at Washington D C on Sept 17 1954 The full text appears in the May issue of *Circulation* published by the American Heart Association.

had much confidence in his powers or promise, his was a brain that developed slowly The stimulus proved to be the shock of realising his ignorance, his inability to understand or deal with the painful problems that faced him daily. One such was the unexpected death in childbirth of a woman under his care from heart failure He could not understand how or why it had happened or how it could have been recognised in time Such events stirred him to discontent, and so he consulted books and journals but found no satisfaction He did not know It did not seem to be known He would find out We cannot doubt that deep feeling has often been the spring of medical research It may thus depend on a man's upbringing and character, and his devotion to an ideal So Mackenzie set to work to study common symptoms like fatigue, dyspnœa, and pain, and to learn their significance by noting their clinical course over the years Impatient only with his lack of knowledge, he patiently took notes and made records year after year with a sphygmograph and later with the polygraph he devised but in which he took little pride Here was a genius for taking pains but a common sense that kept technique in its place as a servant and not a master

It had always been assumed that pain and tenderness arose directly from an organ, but Mackenzie gave the first description of hyperæsthetic skin areas associated with disease of particular viscera He showed that pain and tenderness were referred from an organ to the spinal sensory centres and thence projected to the periphery Such a "viscero sensory reflex" explained the curious extensions of pain in angina pectoris At the same time and independently, Henry Head was elaborating similar views which were published a few months after Mackenzie's

Herrick, whose death this year we lament, wrote "It was largely through Mackenzie's influence that the term 'heart failure' lost much of the opprobrium that had attached to it" Indeed it was not regarded as a proper subject for clinical investigation until Mackenzie convinced the world that the subject of heart failure was of paramount importance in heart disease, and its prevention and treatment the ultimate goal A similar revival of hope resulted from his teaching, based upon long observations on sinus arrhythmia, extrasystoles, and on murmurs which were compatible with good health In a clinical sense he isolated auricular fibrillation, at least in its relation to failure and to its particular response to digitalis

In 1902 appeared that remarkable book *The Study of the Pulse* which had no wide circulation but was quickly seized by the discerning as proof that a great investigator had been quietly at work for twenty years In 1908 came his *Diseases of the Heart*, and in 1909 *Symptoms and their Interpretation*, which together showed Mackenzie to be the most original and vigorous mind engaged in this sphere, and people began to talk of the "new" cardiology What was new was the critical, the scientific approach, and the introduction of hope into what had seemed so largely hopeless

In 1907 he had left general practice for consulting and hospital work in London In a few years he became physician to the Cardiac Department of the London Hospital, where he continued his researches and influenced the many physicians who came to his wards As years went by, he was limited physically by angina pectoris and in 1925 he died in London from cardiac infarction

What kind of man was Mackenzie to meet? He was Scottish in appearance and in accent, a massive figure with a slight stoop His bearded face, with its large brow, was carried by a large and noble head His eyes were searching, twinkling and friendly as his face was lit by a gentle smile, though not too often In general he was serious-minded and looked it, but there was a simple blunt humour near the surface Socially he was warm-hearted without being genial He was gentle in
dealings with patients, especially women, more
towards his assistants, yet appreciative Thus he
mightily pleased with his first resident, soon to be
in the first world war, who took better polygrams
he could himself

Though not by nature of a pugnacious temperam
he was a fighter for his opinions, and he had to be Th
was little appreciation and some opposition from ma
of the older physicians of his day I was warned of th
risks I took by becoming his chief assistant What
universal change there has been in the common atti
towards what is new, when it is true, and for this I
believe we have largely to thank the Americans!

Mackenzie, you will have gathered, found it hard to b
satisfied, yet it was a calm and hard headed man wh
carried that unquiet and inquiring mind More, he wa
a happy man, secretly gratified by his achievements an
their recognition, proud to have such friends as Cushny
Keith, Allbutt, Osler, Wenckebach, and Thomas Lew
and constantly sustained by the deep and abid
affection which existed between him and his wife

Specialism

The second of my three subjects is specialism and the
training of the cardiologist

Specialism has been called the growing point o
knowledge, and it is to specialism, disintegration in
sense, that the splendid advances of the last half-centu
have been mainly due Though many have opposed i
notice that no one has encouraged specialism, inde
that would be superfluous in so natural a process
remember well the time when medicine was held to be
indivisible, and cardiology was not regarded as
integral branch of it The word cardiologist was not
use, or it was used unkindly, whereas today a cardiolog
claims to be as truly a physician as any other The sto
criticism was that specialism engenders a narrowness
view, bad for the doctor himself and for his patie
But, as Hughlings Jackson said "There is no harm
studying a special subject, the harm is in doing
kind of work with a narrow aim and a narrow mind." I
cardiology, as in other branches, a new and broade
outlook has developed, it becomes more and mo
general The true specialist looks anywhere and every
where for the means of cure and prevention All th
physical, mental, and social factors relevant to his ow
subject are considered and integrated by him as the
never were before

In some quarters there are still attempts to for
trained and mature men to abide by the past custom
claiming acquaintance with the whole of general medici
But many young physicians are attracted by the wi
scope and variety of service which a special study of th
circulation and its diseases offers Medicine has divid
It already has children—the present specialties, an
now the grandchildren, the subdivisions—perhaps to b
future specialties—are growing up around us Norm
parents take pride in their offspring and are particul
tolerant towards their grandchildren The subdivi
or differentiation, which has come to pass in medic
as a whole, is now affecting us in cardiology An inst
is vascular disease, and the programme of our cong
proves the fact, for it is full of diverse subjects or
specialties

As a cardiologist, my personal attitude towards furt
specialisation can be simply stated Each individ
should be allowed to make his own choice, as he did w
he chose the profession itself Naturally he will seek
consider advice from his teachers though he is no
at school He may misjudge his own ability or the
for his particular endeavour, but he has a right to ch
the road he will take A wise man—and that could
a young man—should recognise his limitations, bu
must follow his bent The public is aware that

cular disease is predominant in human mortality
licine has always been influenced by public opinion
patients will surely claim the services not only of
eral cardiologists but also of special cardiologists who
e exceptional experience in one variety of circulatory
ease.

ining the Specialist

The serious danger of specialising too early is universally
nitted and it is effectively disallowed in our institu
ns But how long should the training in the sciences
l in general medicine be followed after graduation ?
re I suggest that for the future specialist it may
netimes be too prolonged ? Life is short For how
g should an ophthalmic surgeon restrict himself to
eral surgery and for how long should a young
rgeon remain in general surgery before concentrating
powers and gaining experience in cardiac surgery ?
nilarly a young physician—adequately trained as
ch—may prejudice the fullness of his career if he post
nes for too many years the plunge into what is to be his
e-work. So let us give greater individual choice as to
hich branch of medicine he favours and even, with the
feguards already mentioned as to what stage in his
reer he begins to specialise. I would hesitate more to
ake this unorthodox suggestion that specialisation may
gin too late if I did not know that there is often a
me-back, a natural return to greater commerce with
neral medicine as a man proceeds in his career

mpulsory Research ?

Happily there are plenty of men you cannot keep
om original research almost or actually bloodthirsty
their pursuit of it others only need putting on the
ent and they're off on 'the track of Truth" But
ust every ambitious graduate be forced by custom or
thority to prosecute research in order to obtain a
niversity post or to succeed as a practising cardiologist ?
esearch ability used to be regarded as a rare gift some
ing of a phenomenon. It was search with some prospect
f finding; it connoted both a spirit of curiosity and a
pacity for investigation That is not the attitude
day, though one must admit that it is largely the
pansion of organised research that has transformed
edical practice My question concerns the universality
f the capacity for research and I almost believe that
e true investigator great or small, is born not made
hat famous literary physician Sir Thomas Browne,
rote: "Every man is not a proper Champion for Truth
r fit to take up the Gauntlet in the cause of Verity'
ere is a matter of policy and procedure in our profession
hich will have to be decided. In my view we encourage
od men inapt for original research to sacrifice their
me and energy upon it when they should be perfecting
emselves as bedside physicians Are we losing our sense
proportion exhilarated by the wonderful products of
cent and current research ? Is a born investigator a
perior being to a born clinician and teacher ? He may
may not be Advances in medicine comprise two
parate stages: first the discovery of something new
d valuable as a result of investigation secondly the
plication of that new discovery to the benefit of the
dividual patient The same man may not be the right
e for both stages though he can be

Though commoner than aptitude for research the
wer to apply new (and old) knowledge judiciously is
t given to everyone It also requires a gift—namely
inical judgment This will ripen to clinical wisdom
ly by constant association with the sick Young
ysicians of this type—so badly wanted—need to keep
emselves abreast of the world literature in their
ecialty and devote time to postgraduate clinical work
other centres and in other lands Must they invariably
forced to shorten the time required for this large
rpose to participate in minor and often ephemeral
research before they are considered for any important staff appointment as a teacher or consultant ? Not every young physician or cardiologist should be under compulsion to prosecute individual research in order to succeed.

It would not be surprising if the magnitude and the magic of recent advances went to our heads The secret places of the heart are probed or rendered visible. The blood is directed where it may run and under orders when it may clot now even its channels are to be kept clear of their silt But after all scientific truth is discovered not created by us and knowledge is not always progress Some will remember the warning given by Professor Laubry at the European Congress of Cardiology in 1952 about the peril of technical dogmatism and the need to retain a measure of salutary doubt There is always a limit to scientific certainty in medicine, and some humility of approach is therefore becoming In fact, it is probable that we are producing both truth and error as our forbears have done The circus theory of auricular fibrillation for example seems to have come and gone but happily no patient has been allowed to suffer from this physiological disaster !

Research Applied

The original worker in research is fully aware of the importance of his subject and cannot be held back Are we as aware of the immediate importance of that other pressing duty that of applying the safest and soundest treatment to the sick of today ? I mean getting it applied more certainly and more universally If our minds are possessed by the greater things research will do for them in the problematical future, we may be less mindful of the *mass of human illness requiring our best endeavour* today The vision of new truth should not blind us to our bounden duty as doctors Any hospital may be proud of the amount of research being conducted within its walls But it should be equally proud of a reputation for applying—in current practice to the patients under its care—the sum of accumulated knowledge, the best treatment in the world today In this connection may I venture the opinion that the governing bodies of teaching hospitals would be wise to retain on their staff and value the services of an adequate number of practising physicians These should not be sacrificed at the altar either of science or of uniformity with loss to medical education and to the community *Indeed, a medical* staff will never be uniform, and the establishment should always be flexible enough to fit the exceptional individual and the late-developer and to take full advantage of any new perhaps unexpected, discovery

Unity and Friendship

I have touched on several problems for which, I doubt not solutions will be found or will naturally emerge Meanwhile we must be prepared for change willing to allow our younger gifted men freedom to strike out on their own lines according to personal inclination and judgment The call is to adapt ourselves to the changing form that cardiology is taking rather than to attempt to maintain its earlier compactness or to keep a strict symmetry in our organisation If only we cultivate the good feeling so evident at our congress we need have no fears for the future. Most of all the bond of unity will continue to lie in the grandeur of our purpose—namely the prevention relief, and cure of cardiovascular disease

When one speaks of unity and of leadership your thoughts will go at once to the president of our congress Dr Paul White Friendship for a country rests largely on personal friendships with its citizens. On that basis though not solely I would pay my *tribute to the lead* taken by the United States in the realm of cardiology and also give thanks for the close friendships which have bound me to this great country We spoke of hero worship, and Paul White remains one of my abiding heroes A counterpart to Osler in medicine, he has been an ambassador of good will and good hope to cardiologists all over the world He has made many original contributions, and by means of his famous book he has proved a trusty unseen consultant to countless doctors In it he has reverently combined a choice of the past with the best of the new

The French Contribution

Finally I want to say a little about the course of cardiology in France in recent years Following Potain there has been an unfailing sequence of distinguished cardiologists among French physicians First came pure clinicians like Merklen and Huchard, but it was the work of Vaquez, who combined the traditional French *clinique* with the physiological methods and researches of Marey and François Franck, that marked the beginning of contemporary French cardiology Apart from Laubry himself, to whose achievements I will return, we record with admiration the fine influence of Clerc, the brilliant observations of Gallavardin of Lyons in clinical cardiology, and the example of Giraud Then I would draw your attention to the constancy and the quality of the work of Professor Lian, a physician remarkable for his clinical discernment These have been followed, in strength, by Soulié, Lenègre, Froment, Heim de Balsac, Routier, and others

Inspired by the work of Helen Taussig and Blalock, and by their auspicious visit to Paris in 1947, Professor Donzelot and Professor d'Allaines, physician and surgeon, have combined in the last few years to make an important contribution from the cardiac centre at the hôpital Broussais This year, that work has been published by their brilliant co-workers, in particular Heim de Balsac, as a *Traité des maladies congénitales*, a large volume richly illustrated, and perfectly produced That is true also of another up to date French treatise for reading and reference, *Électrocardiographie clinique* by Lenègre and his colleagues

The contributions of France would be more widely evident today if it were not for the unfamiliarity of the English speaking countries with that graceful language We should all gain by a hearty understanding with France, a medical *entente cordiale* The place of France in the civilised and cultural world cannot be shaken by the passing effects of war or by political vicissitudes

Too often Paris has been solely a place for sightseeing and gaiety, and that was largely true in my own case On an early visit, however, I was privileged to go round the wards with the great Vaquez, who was attended most devotedly by his *chef de clinique*, no other than Laubry himself As Evan Bedford has said, " The great traditions of the Paris school of cardiology have been handed down in direct line from master to pupil for over a century, starting with Corvisart and passing in turn to Bouillaud, to Potain, to Vaquez, and finally to Laubry " Tradition may be a source of strength and a justification for authority To Laubry was bequeathed that authority and we realise today how valuable it has proved for the continuity of French cardiology under the trials of recent years Notice that he has been content to make this branch of medicine his life work, and the chair of clinical cardiology in the University of Paris was created for him

To begin with, he has been a brilliant clinical teacher, directly influencing students and graduates from the whole continent of Europe and elsewhere Lenègre has described those fascinating bedside clinics by the *patron* as reaching the unity and the charm of *a cardiological* ballet—though he allows that sometimes there might also be a display of fireworks !

Then since 1936 he has been the director of the *maladies du coeur*, founded by Vaquez in 1908 In the following year, he founded the Society of Cardiology Lastly, he has steadily tributed original research by way of clinical intuition synthesis combined with precise laboratory methods The work of his pupils bears testimony to his leadership and the important theses produced year after year under his direction indicate the scope of his interests and his capacity for guidance His son, Dr Pierre Laubry, has also made valuable contributions

Professor Laubry has methodically assembled his vast knowledge in book form In 1921, he published with Pezzi, a treatise on congenital heart disease In [illegible] appeared his famous *Leçons de séméiologie cardiovasculaire* and in 1930 his large textbook on heart disease One of his favourite subjects has been gallop rhythm, on which he wrote, with Pezzi, a valuable monograph Interested by Vaquez and Bordet in cardiac radiology, he instituted with Chaperon a long and painstaking research on the radiological anatomy of the heart and great vessels, normal and pathological, using radio-opaque injections The results appeared in two large volumes in 1939, *Radiologie clinique du coeur et des vaisseaux* by Laubry in collaboration with Cotte Routier, and Heim de Balsac It has provided a scientific basis for cardiovascular radiology, in particular, the composition of the vascular pedicle and the lung shadows was elucidated, and you will remember concept of the small aorta—large pulmonary artery 1950 appeared the second edition of *Les maladies coronaires* with Soulié, a comprehensive and modern textbook In the same year, to the amazement of those who had not appreciated the depth of his scholarship, for he carries his learning lightly, came his own translation into French of William Harvey's *De motu cordis* (1628) We in Britain especially value this tribute from one we are proud to number among the fellows of the Royal College of Physicians which the illustrious Harvey himself adorned

The outcome of a man's life may be measured by the ratio between his natural gifts and opportunities, and the service that he dedicates to the common good You will agree *that it is not only his talents but the* use he has made of them that has won for Professor Laubry the unique position in the cardiological world He possesses all the elements of greatness, and they are still manifest after an unusual experience in living, for he has passed his 80th year *In his long pilgrimage*, by teaching research, and personal example, he has set himself quicken and confirm progress in the wide realm of cardio-vascular disease, so that he has provided a veritable pattern of leadership

---

PREVENTION OF JUVENILE DELINQUENCY

Two types of children come before the juvenile courts —mischievous young law breakers and unhappy problem children Sir BASIL HENRIQUES, who classified them this way when giving the Peter Le Neve Foster lecture at the Royal Society of Arts on April 27, finds the weakest part of child-welfare work in England to be preventive side

Many of the children born between 1939 and the of the war were separated for years from their parents and lived among strangers When the time came return, their mothers had become strangers and sometimes the children now had less liking for their mothers than for the foster-parents they now had to leave When their fathers came back from the Forces they too become strangers—*not only* to the children but times also to their mothers and the strangeness of parents to one another was as devastating to the children as their own strangeness to their parents Some of mothers had acquired new interests and did not welcome n back with the love and enthusiasm about which y had been long day-dreaming and some of the ers brought an almost military discipline into the ne, while some were over indulgent The war, in fact duced not only many problem children but many blem parents

The mischievous young law breakers Sir Basil finds ordinary boys with plenty of initiative and courage no proper outlets for their high spirits (This has n the experience of other observers: John Barron ys[1] noted that Liverpool boys often commit offences rely because they need to prove their courage to one other) Only some 46% of those committing crimes this country are detected, and every young delinquent urally expects to be among the 54% who are not ught Three things, Sir Basil suggested are needed prevent these crimes of adventure: first a police ce brought up to full strength and with better methods detection secondly enough playgrounds and sports unds for children and young people; and thirdly portunities for them to spend their leisure in a useful d constructive way He believes that the various youth ganisations could give them such opportunities, but at these organisations are chiefly handicapped by lack leaders of the right kind Pearl Jephcott,[2] however her study of membership of youth clubs found that ly about 1 in 3 children join clubs—and these are not cessarily the children who would profit most from em. Green spaces sports gymnasium and boxing ight attract more of those who now fail to join but at esent few youth organisations can offer all these things

THE UNHAPPY CHILD

But it is not in Sir Basil's view, the adventurous child much as the unhappy disturbed unsettled child who esents problems to the juvenile courts Lack of ordination between the various agencies dealing with prived and difficult children often results in failure to ke action as soon as anything amiss is noticed in child family He spoke warmly of the example of New South ales where every aspect of child welfare comes under e ministry which has concentrated on preventive rk Juvenile welfare in our own country is parcelled t among the Home Office and the Ministries of ucation Health and Labour

Abnormal behaviour in a child nearly always means at he is unhappy at home and many people have the ance to see his symptoms—the health visitor the rsing manager the staff of the nursery school or day rsery his teachers in his primary and his secondary hools the leader of his play centre his officers in the bs and Scouts his club leader the youth employment icer and (at every stage) his neighbours Some of se watchers are bound to realise when all is not well th him; but they are not clear what to do about it d often nothing gets done

He quoted the case of two little girls now aged 5 and 6 ose mother had died two years ago and whose father had en as his second wife a girl who had absconded from a ony of mental defectives Since there were now two rents to look after them the children (who had been in the e of the local authority) were sent home The teachers their school noticed that they lost weight and seemed ravously hungry and put them on school dinners. In the ter weather at the beginning of this year they came to school dly shod and in cotton frocks. They often said that they re frightened of their father and asked leave to keep their ts at school lest he should destroy them One afternoon y cried hysterically and refused to go home and their her called in the police and had them brought before the rt as in need of care and protection

Thirteen months earlier the health visitor had referred e case to the National Society for the Prevention of Cruelty to Children; and neighbours had also reported to the society that the children were never allowed to play in the street but were confined in a small back yard where there were rats If they were naughty they were put in a corner of the yard, and, if they moved the dog of which they were terrified was let loose

Sir Basil pointed out that the children's officer the school care committee, the education department and the after care officer for mental defectives (who was supervising the stepmother) all knew about this family yet these children had been allowed to suffer for many months without remedy

A CHILD WELFARE OFFICE ?

He suggests that we should establish in every town and in every district of cities, a child welfare office to which anyone concerned about the well being of a child can go for advice and guidance It should be a building worthy of its purpose presided over by the children's officer as director of child welfare and it should contain the headquarters of all the statutory and voluntary bodies which deal with the welfare of children This is no more dream, for in Manchester many of the voluntary agencies concerned with children already have their offices in the same house The juvenile court he thinks should hold its sessions in a room in the child welfare office—a suggestion which would not win the support of C A. Joyce headmaster of the Cotswold School, who believes that the juvenile court ought to impress the child, not give him the idea that whatever antisocial thing it was he did hardly matters. The great advantage of housing all the welfare agencies under one roof of course is that a family needing help can be referred at once to the appropriate body Thus parents persuaded to consult the probation officer could do so on the spot before their moderate ardour for his advice had time to cool

FAILURES IN PREVENTION

One great weakness in our present system Sir Basil thinks is the relatively slight attention we pay to absenteeism from school yet this is a sure sign of something wrong somewhere School inquiry officers are among the most poorly paid of local authority servants They should he suggests be highly trained family case workers employed not by the education but the children's department and it should be their job to discover the real reasons why the child is staying away—the negligence of the mother or her demands for the child's services in the home or the child's own failure at school which has led him to play truant Moreover if he was a trained child welfare officer teachers would tell him not only about absentees but about children sent to school dirty or persistently late children showing behaviour problems, and children, lately cheerful who have become sullen and morose

Sir Basil spoke of our failure to prevent some of those who leave borstals or approved schools from committing further delinquencies—blaming a system which reforms the child and sends him back to the unchanged home conditions under which he broke down 'Work on the family of a child or young person committed to a school or borstal,' he says, 'should commence the very day he enters the school. He proposes that all children under 15 who need residential training should be committed to the care of the local authority this would place the local authority *in loco parentis* until the young person reached 18 Approved schools for children under 15 would under this arrangement become members of a pool of ' residential schools ' ; and the local authority could send the child to the school appropriate to his needs—whether it was one specialising in delinquents or an ordinary school As no authority would wish to have more children in care than necessary, there would be an incentive, at present lacking, to get the home improved as quickly as possible This proposal has all the charm of orderliness, but it is hard to be sure that the irresponsible parents would really benefit from having their duties taken over by the local authority, or that the child would gain in security from learning that he was no longer under the control of his parents It is a situation calling for much careful thought

---

A MINISTRY OF JUVENILE WELFARE?

Finally Sir Basil would like to see the children's department of the Home Office, the Ministry of Education, the National Youth Employment Council of the Ministry of Labour, and the department of the Ministry of Health which deals with children of school age and under, combined to form a Ministry of Juvenile Welfare, a minister of Cabinet rank This idea too has attractio its weakness is that it separates the child's situation that of the family as a whole—and this, as we are and painfully learning, cannot be done Perhaps one towards a coordination of services is to begin at the end, as the *Times* (April 28) suggests, by training a set of "general-practitioner" family case workers replace the multiplicity of inquiring people now visiting the homes of families with problems Like her counterp in general medical practice, she would be able to ca just the agencies which could help, thus coordinat their efforts from the start.

Public Health

THE POLIOMYELITIS-VACCINE CONTROVERSY

FROM AN AMERICAN CORRESPONDENT

THE announcement on Franklin D Roosevelt's birthday of the effectiveness of the Salk vaccine in protecting against poliomyelitis was greeted in the United States with great satisfaction both by the lay public and by the medical world Since then there has been a tremendous hullabaloo which has been and is being stoked up by the press, radio, television, and the Poliomyelitis Foundation For one thing, there has been an argument about the distribution and use of the vaccine, and this has been engaging the attention of the United States legislative bodies, organised medicine, the trade unions, and the pharmaceutical houses The public want the vaccine "for free" (as they say) they have contributed generously year after year to the March of Dimes fund of the Poliomyelitis Foundation and they feel that they have bought their share of this advance On the other hand, the pharmaceutical firms need to recover their investments and wish to make a profit for their stockholders, while doctors, with no national health service behind them, quite properly want to charge for giving the injections

Much more disturbing was the announcement that poliomyelitis had developed in a number of children who had had vaccine prepared by the Cutter Laboratories, and this vaccine was withdrawn from general use While the facts and the possible explanations have been presented at length in the press, a much quieter scientific controversy was going on, and this has been brought into the limelight at the annual meetings of the American Society for Clinical Investigation and the Association of American Physicians which were held last week at Atlantic City Dr Jonas Salk and Dr Albert Sabin have long held opposing views about vaccination against poliomyelitis For many years they have presented their hypotheses at medical meetings, but this year they came up with facts, and it looks as though Sabin may be right He favours the use of attenuated-virus vaccine given by the natural route of infection (by mouth), while Salk believes that formaldehyde killed viruses given parenterally will produce antibodies as effectively as and more safely than modified living viruses Sabin has contended that intramuscular injections of killed vaccine will not confer lifelong immunity and that it would be impracticable to re vaccinate each time the short lived artificial immunity runs out If children received such a short term vaccine, he argues, there would soon be a population of young adults with no protection against poliomyelitis, and as the disease is more severe in adults than in children, a vaccine which confers only a short immunity might eventually result in many severe illnesses when the children grew up This situation is already developing for a different reason in the United States Great Britain, for example, where standards of hyg are high and natural infection is therefore relativ uncommon The exact duration of immunity confe by the formalin killed vaccine cannot yet be known. Salk has suggested, on the basis of studies on a lim number of subjects, that the immunity will be life-long

Salk's short paper given at the annual meeting of American Society for Clinical Investigation was his presentation of data collected from last year's huge test of the action of polyvalent vaccine in produ *antibody in children* *Three serial injections* were g and antibody titres were measured at frequent inter before, during, and after the vaccinations The first vaccinations were given close together, and the th or "booster" injection a variable time later Sal found that the immunological response to poliomye virus antigen in man was made evident by two measur reactions—the antibody response itself and the sta hyper reactivity to subsequent antigenic stimulation. *the hyper reactive state there was a shorter* inte between provocation and secondary antibody resp and the secondary response was very *much greater* th the primary one The degree of the secondary resp was shown to be influenced by the intensity of prim stimulation, the intensity of the secondary stimula and especially by the interval between primary secondary stimulation The full secondary effect in could not be elicited unless the secondary stimula was given several *months after the primary* inject These factors were also found to influence the degre which the serum antibody *levels tended* to pe Immunological response in man, following injection non-infectious poliomyelitis virus vaccine, was affe by previous immunological experience with one or of the three types of viruses, responses being striking with previous exposure to type III virus. also suggested that the presence of *measurable* amo of circulating antibody in children *may not* be an essen prerequisite for immunity to paralysis In some chil no antibodies were found in the blood, yet they respo to the primary injection by a rapid rise in antibo which persisted in the blood *It seemed clear* that t children had been previously exposed to natural p myelitis without getting paralytic disease Salk s lated that the hyper reactive state was an impor protective mechanism against natural poliomyelitis believed, on the basis of this work, that natural rea tions with poliomyelitis after invasion through natural portal of entry, will stimulate promptly formation of antibody and thereby limit deeper inva *or further multiplication* of the virus The ex question of life-long immunity could not be answ at present

Sabin, who is director of the research unit of Children's Hospital of the University of Cinc Medical School, presented his investigations to the A ciation of American Physicians He has deve mutant attenuated strains of virus which, when g chimpanzees by the natural oral route provoked the velopment of antibodies in the circulating blood and nferred 'life long' immunity to the three types of ralytic poliomyelitis virus The chimpanzees had no ognisable illness as a result of exposure to the atten ated virus and these viruses have never reversed their tations to reappear in the virulent paralytic form for the chimpanzees Sabin described a dramatic experiment ith 26 young volunteers in the Federal reformatory at illicothe, Ohio Varying doses of living attenuated us were given to the men in a drink of milk and tibody titre was measured serially Repeated cultures re collected from the mouth throat and fæces tibody formed rapidly, and has so far persisted in e blood Virus could not be recovered from the mouth, it was recovered from the throat and fæces With ge doses of virus the stools have remained positive up to three months The minimal dosage was 001 ml of the pure culture This amount of virus voked excellent antibody response when swabbed on e throat of the volunteers. No illness appeared in any the volunteers nor in the men who were in close ntact with them in the reformatory Sabin stated at when comparative studies had indicated the best ains to use, it would be *possible to determine* whether not the optimum attenuated poliomyelitis virus—her given in milk or simply swabbed on the throat—uld be used for primary immunisation or for production an effective type of immunity in individuals temporarily tected by natural antibody or non infective vaccine

It was clear that many doctors at the meetings feared t the public had been too readily convinced that liomyelitis had been conquered For there are many ering facts for example quite apart from any ention of infective batches of vaccine many vaccinated ldren will get poliomyelitis for the Francis report de no higher claim than that the vaccine was effective 60–90% of those who received it

Issue of American Vaccine Suspended

Further supplies of poliomyelitis vaccine will not be ued in the United States until an inquiry into manu turing standards and safety tests has been completed nouncing this on May 6 the Federal Surgeon General, Leonard Scheele said that the vaccine was still ing produced but Federal approval of additional pplies was being held up for several days.[1] Scheele was testifying before the banking committee the House of Representatives on pending bills that uld give the government power to control the price d distribution of the vaccine. He was confident that experts now examining the situation would conclude at the vaccine was excellent and that vaccinations ould go on It would be decided in the next few days ether the vaccine would continue to be tested by spot ecks as at present or whether every lot should be amined Dr Scheele said that on May 6 the total cases of poliomyelitis in newly vaccinated children 11 of whom 38 had been given Cutter vaccine ked whether this vaccine was now suspected he lied: We have to have a lot more evidence before could decide[2] Since April 1 he said there had en 384 cases of poliomyelitis in the United States, mpared with 423 in the same period last year

In a report issued two days later Dr Scheele announced at a detailed reappraisal of each lot of vaccine already pared or in final stages of production was being dertaken[3] He hoped that vaccine would be available use again by the end of this week There had been cases of poliomyelitis among more than 5 million ople vaccinated, and if only 1 in almost 700 000 ldren inoculated with vaccine from companies other an Cutter Laboratories had incurred paralytic polio-yelitis Dr Scheele added this meant there was every ason to believe a product of the other manufacturers is safe He said there was a definite association between the Cutter vaccine and the cases of poliomyelitis that had developed after its use So until the precise cause was found the vaccine produced by this laboratory would remain suspended

The Medical Research Council has sent a member of its staff to the United States to obtain first-hand information. This should be available before the routine safety tests on the present batches of vaccine are completed and therefore, before any proposed trial in this country is due to begin Meanwhile, the council will continue with the arrangements for starting the trials.

Cadmium Poisoning

The industrial diseases subcommittee of the Industrial Injuries Advisory Council is considering whether cadmium poisoning should be a prescribed disease under the National Insurance (Industrial Injuries) Acts, and if so for what occupations. Industrial injuries benefit can already be claimed for acute cadmium poisoning as injury by accident. The committee are inquiring into the possibility that prolonged exposure to cadmium at work can give rise to chronic ill health against which insurance cover should be provided Persons and organisations interested in the question of prescribing cadmium poisoning are invited to submit written evidence Communications should be addressed to the secretary, Industrial Injuries Advisory Council, 10, John Adam Street London, W C.2 to arrive not later than June 6, 1955

Medicine and the Law

State of Doctors' Surgeries

Two decisions by the London Executive Council at its meeting on April 28 concerned the duty of practitioners under the National Health Service to provide and to permit the inspection of proper surgery accommodation Clause 7 (4) of the Terms of Service requires the practitioner 'to provide proper and sufficient surgery and waiting room accommodation for his patients having regard to the circumstances of his practice Clause 7 (5) provides that on receipt of a written request the practitioner shall at all reasonable times admit any member or officer of the council or the local medical committee authorised by the council for the purpose of inspecting the surgery or waiting room.

In the case of Dr A an inspection was made in February, 1955

Dr A's surgery hours were from 11 A.M. to noon but when the inspecting officer called at 11 40 A.M., Dr A who apparently slept in the consulting-room was not ready to receive patients In the waiting room was a quantity of old paper, a dilapidated leather trunk and a tin box The consulting room was in a state of muddle The floors had no covering and had not been swept The visit was paid when there was snow on the ground, but there was no evidence of a fire in the waiting room, although Dr A said that a fire was provided when required There was no running water in the consulting room and no light in the lamp holder in the waiting room, and in both rooms the windows and curtains were dirty

Dr A was invited to submit observations and to attend a meeting of the medical service committee He failed to do either The executive council adopted a recommendation that representations should be made to the N H S tribunal that the continued inclusion of the practitioner in the council's medical list would be prejudicial to the efficiency of the service

The case will now be subject to inquiry by the tribunal

In the case of Dr B the local medical committee had asked for an inspection of the surgery and authority had been given by the chairman of the council

Dr B agreed to receive the inspecting officers and the hearing was fixed for March 11, 1955 Dr B subsequently wrote stating that the date was inconvenient as decorations to the premises had not been completed and the council to defer the inspection until the middle of The council replied that they had not asked that the should be re decorated before inspection. Dr B was that the duty of the inspecting officers was to report to council on the present condition of the premises and that information he gave as to re decoration &c, would incorporated in the report The apparent reluctance of doctor to permit the inspection of the premises was to the notice of the appropriate committee on March and on the following day the doctor was notified that committee had decided to refer the matter to the service committee unless he indicated several days the ensuing fortnight on which the surgery could inspected No reply was received from Dr B

The medical service committee considered that had shown a complete disregard of his obligations the Terms of Service and they advised that a mendation be made to the Minister of Health the sum of 30 guineas be withheld from his remuner The executive council adopted this recommend which is subject to appeal

Parliament

Review of Social Services

In the House of Commons on May 4 Dr Edith Summerskill, in opening a debate on the social services, regretted that the report of the Phillips Committee on the economic and financial problems of the provision for old age, had been ignored by the Government She pointed out that the new scales would not help the old-age pensioners on National Assistance Of those on sickness benefit 123,000 would only get 2s 6d extra, and most of the people receiving this benefit were the chronic sick This led her to ask the Minister of Health if he was satisfied that, having regard to the hardship it imposed, and the administrative burden it entailed, the shilling prescription charge should be continued? Had the Minister inquired in districts where industrial processes had a deleterious effect on the workers' teeth to see whether withholding a free service had resulted in a deterioration of dental health? She understood that £50 million was spent annually on drugs, 30% of which went on proprietary drugs She found it difficult to understand how the Minister could allow this huge sum to go on swelling the large profits of the big drug houses, knowing how cheeseparing he was in other directions The Minister had been trying to persuade doctors to use cheaper alternatives, but he had done everything except take strong action He should refuse to sanction unnecessary expense in prescribing when there was a satisfactory alternative

Mr Iain Macleod interposed that Dr Summerskill's suggestion might infringe the right of a professional man to decide what, in his judgment, was best for his patient Though advice had been given to doctors that certain drugs were not of proven therapeutic value, if a doctor in his own discretion still decided to prescribe one of them it was perfectly legitimate for him so to do

Dr Summerskill went on to ask if the Minister thought he was justified in allowing hospital beds to be earmarked for fee-paying patients when in some districts there were long waiting-lists, and whether he could report any improvement of conditions in our mental hospitals

Mr Osbert Peake, Minister of Pensions and National Insurance, described the Phillips report as "most valuable" and said that it was clear that as a result of it there would have to be legislation at a later date amending the National Insurance scheme But he thought the scheme was a good one and he would be reluctant to introduce changes into it just for the sake of changes He had been assured by the National Assistance Board that the increases in February had fully restored the loss of purchasing-power of the allowances which had occurred since June, 1952 In July, 1948, the Assistance Board were paying 842,000 allowances, that figure had risen by the end of March, 1955, to 1,807,000 increases in pensions would reduce by 100,000 the num going for assistance

Mr Kenneth Robinson returned to the case of boy with a fractured and dislocated arm who had at Hampstead General Hospital for more than six before he received medical attention Mr Rob had found the Minister's reply about this case satisfactory[1] But the matron immediately began give interviews to Press reporters in which she said she had not heard of anyone being reprimanded explained that the boy had been kept waiting for hours because it had been impossible to get a spec in the hospital sooner, and that he had not been food or a sedative because he was to have an anaesth Mr Robinson shared the great respect and gratitude the House and the country had for the nursing profe but it seemed to him that some members in the ranks of the profession were rather resentful of critic The matron of this hospital had in effect repudiated Minister's apology and Mr Robinson felt that the could not be left there

Mr Macleod agreed that Mr Robinson was to raise this case in the first instance and, in view of statements which had been made, he was wholly rig raise it again He, like Mr Robinson, had hoped with the full apology which he had made on behalf the board of governors, and in particular on of the Hampstead General Hospital, the matter had closed He had been considerably startled to read in newspapers the comments which the matron had The answer which he had given to the House on was made after consultation with the board of gov and it had the agreement and encouragement of people responsible From time to time one got impression that the people concerned in these were a little reluctant to admit that they were in because they thought that might reflect upon a h of which they were rightly proud In his view that a wrong attitude If a fault was found, nothing hospital more credit than to say that it was wr and it was right that an explanation should be frankly to the House of Commons by the Min responsible, as had been done in this case Be hospital had slipped in one particular instance, it did mean that it was not a fine hospital with fine as he was quite certain was the case here We all ad the quality of loyalty and he could easily under a matron who was proud of her hospital and the working there resenting, perhaps a little too any suggestion that the hospital had slipped in its But what had been said was unwise and unf it should not have been said, and he was certain that matron much regretted having made an allegation he understood she had—against Mr Robinson himself urning to the question of prescribing Mr Macleod that it was entirely within a doctor's discretion to scribe a particular drug even though it had been gested by the committee and Ministry that this was advisable He would not be surcharged for that as possible—and this was a different point—that his scribing as a whole might be looked at, and one element ght be the over-prescribing of one particular drug Macleod did not see how they could achieve what Summerskill seemed to have in mind which was ited to the prescribing of the ordinary substances the list without interfering with the ordinary clinical edom of doctors He would not wish in any way to erfere with the right of a doctor to prescribe at his cretion in individual cases The total bill for England d Wales for medicines was about £43 million not luding hospitals, and within that sum £21 million a little more than half was due to proprietary medies. That was cost alone the non proprietary preiptions would be more than half because the others re more expensive Many of the greatest discoveries, h as the antibiotics, had been made by private firms garding the pattern of dental treatment, Mr Macleod d that the important fact was that conservative atments had gone up from 4 070 000 in 1951 to 00,000 in 1954 that in the school dental service the mbers, which had fallen at the end of 1951 to 713, d risen at the end of last year to 979 The dental atment of the priority classes was a great deal better n it had ever been

---

[1] See *Lancet*, May 7, 1955, p 966

About 1% of the beds in the National Health Service re private beds and about a third of those at any given e were occupied by non-paying patients, either on unds of medical urgency or to see that the beds were ed The proposal to abolish pay beds was a breach faith with millions of people who paid into contributory emes so that they might have some privacy in spital.

The mental hospitals had no waiting list, and the 8500 ls that were being provided were a contribution to the ief of overcrowding For the mental-deficiency spitals there was a waiting list of about 7000 5007 ls had been completed, or were nearly complete, d there were also 915 beds included in the 1953–54 gramme, not all of which could be actually occupied There was therefore a programme of at least 00 beds as against a waiting list of something like 00 But the Government had recently announced substantial hospital building programme and the ntal-deficiency side would get its full share

Prison Reform

In the House of Lords on May 4 Lord PAKENHAM in ling attention to the Prison Commissioners report for 53 said that he had lately shared in an inquiry, under en on behalf of the Nuffield Foundation into the es of crime, and in the last year or two he had ited some 20 prisons or borstals. He submitted that xt to nothing was being done to reform the majority convicted prisoners indeed it might well be argued at they were likely to come out of prison worse than en they went in We were not making an effort in s direction commensurate with our degree of social lightenment in other fields

The overcrowding of our prisons—the fact for instance, at out of 17 485 in prison 2880 were still sleeping three a cell—was a sore impediment to the best intentioned ison staffs. The most troublesome bottleneck which day frustrated the efforts of all who would like to extend e training system using that word in the sense not ly of trade training but also of moral training was e shortage of staff Today the three-shift system was force in only a quarter of our prisons But without the idea of individual treatment for prisoners would main a fantasy It was a major and imperative duty ther to bring down sharply the number of prisoners to increase rapidly the number of staff

Viscount TEMPLEWOOD pointed out that only 21 000 en and women were involved Surely a welfare State th all the immense improvement that we had seen in ery social service could deal with this small problem an urgent and common-sense manner Yet instead of progressing, so far as accommodation and work went we had fallen back 50 or 60 years. He urged that there should be an inquiry into all prisoners records to see how many of them could be allowed to work outside prison Work in prison should be useful and paid for at regular rates. The money should be allocated to the man's keep, compensation for the victims, and the provision of a sum for the prisoner when he left prison The best hope for many offenders was to make them work and make them take an interest in it Lord MOYNIHAN suggested that there should be compulsory aftercare for boys of 14–17 who were sent to detention centres He would like to see the system of ' home leave extended and given not only to those who had happy homes but also to the homeless He was sure that carefully selected families would be prepared to take these boys in the first weeks of their probation The appointment of permanent welfare officers in prisons would be a great step forward

Lord MANCROFT, joint parliamentary under-secretary of State for Home Affairs, said that the prison and borstal population in 1930 was 10 000 and by 1952 at the peak it had reached 24 000 Since then it had gradually decreased and was today about 21,000 The effect of the sharp rise was that in 1952 there were 5200 prisoners sleeping three in a cell That figure was now down to 3000 Nothing but necessity excused that deplorable state of affairs Oddly enough, this situation had had little effect on health and discipline, but it remained wholly undesirable Overcrowding was not allowed to interfere with training in specialised prisons; its effects had been confined to local prisons. The plans for new prisons were based on the bold decision to break away from the traditional walled prison and to place in open conditions all who could safely and properly be trained there. There was no shortage of men coming forward for posts as prison officers, but they were not always the right men Recruits were urgently needed There had been a shortage of work in the prisons, but the past year had shown improvement In all specialised training prisons there was a full working day in good class industrial work. The treatment of prisoners was now dominated by the conception of training The Government stood by that conception and believed it to be wholly right and proper

Full use was being made of the detention centres by the Courts, and it was hoped to widen the system The centres were making an effective contribution in combating juvenile delinquency Many prisoners who had otherwise been written off as hopeless had been saved from a life of crime by flexible methods of corrective training Greatly increased medical services had been set in progress since the war in local prisons, directed towards rehabilitation—particularly psychological and psychiatric services rehabilitative surgery and specialised treatment under the National Health Service, both in outside clinics and in hospitals While there was still great room for improvement there had been a great effort to improve the Victorian sanitary conditions in prisons and this effort would be continued The whole process of aftercare for prisoners other than in local prisons, had been reorganised by the formation of a Central After-Care Association, and by the decision to bring in the probation officers as field workers for the association Every prisoner in the care of the association after his release was under the immediate supervision of a skilled social case-worker

QUESTION TIME

Review of Extraction rates of Flour

Replying to a question Mr HEATHCOAT AMORY Minister of Agriculture and Food said that he had decided in conjunction with the Secretary of State for Scotland and the Minister of Health to arrange for an independent authoritative review of the scientific and medical evidence now available in regard to this matter Lord Adrian president of the Royal Society had nominated for the conduct of this review the following panel of representatives of scientific and medical opinion:

Sir Henry Cohen F.R.C.P. professor of medicine University of Liverpool (chairman) L J Witts F.R.C.P., professor of clinical medicine, University of Oxford J H Gaddum, SC D, M R C S F R.S, professor of materia medica University of Edinburgh A C Chibnall SC D F R.S, formerly professor of biochemistry, University of Cambridge R A Morton D SC., F R.S professor of biochemistry, University of Liverpool

The terms of reference of the panel are

In the light of the scientific and medical evidence now available to determine the differences in composition and nutritive value between (*a*) National flour as defined in the Flour Order 1953, (*b*) flour of extraction rates less than National flour as defined in the Flour Order 1953, to which the three token nutrients have been restored (*c*) flour of extraction rates less than National flour as defined in the Flour Order 1953, to which the three token nutrients have not been restored and to advise whether any such differences are significant from the point of view of the health of the population

Poliomyelitis Vaccine

Replying to a question, Mr J R BEVINS, as representing the Lord President of the Council, said that the current programme of poliomyelitis research coördinated by the Medical Research Council might show whether there was any practicable alternative to the use of monkeys in preparing a poliomyelitis vaccine, but he was advised that an adequate substitute for monkeys was unlikely to be found in the near future for a vaccine of the Salk type It was hoped, however, that adequate supplies of monkeys would be available again shortly He could give an assurance that research to find a promising substitute was going on Before any of this type of vaccine was used in this country it would be very carefully tested on monkeys or some other animal

Replying to a further question, Mr MACLEOD said that recently reported events in America were being fully considered by the M R C, and a member of their staff was going over there immediately to get first hand information This should be ready for study here before the routine safety tests, now being conducted on batches of vaccine, were finished and therefore before any of the proposed trials on children over here were due to begin Meanwhile arrangements for these trials continued There was no intention of inoculating any child unless the full consent of the parents had been first obtained

Postal Votes

Replying to a question, Mr IAIN MACLEOD said that he had studied carefully the documents sent to him about pressure being brought to bear on doctors by local Conservative associations to send them the names and addresses of their sick, blind, and aged patients for the purposes of the postal vote It was desirable that everybody should be aware of their right to a postal vote and equally important that any information given should be made available to all political parties who asked for it There was nothing wrong in responsible citizens, doctors or others, bringing to the notice of those concerned, whatever their politics, their rights as postal voters On the specific question about extracting patients' names from doctors' lists, he would not expect information concerning doctors' National Health Service patients, which was normally regarded as confidential, to be disclosed for some entirely different purpose He was sure that doctors understood the position and that no special communication was necessary

Welfare Foods

Replying to a question, Miss PATRICIA HORNSBY SMITH gave the following figures for the distribution of welfare foods

Welfare food	1953 July–Dec	1954 Jan –June	1954 July–Dec
National dried milk (millions of tins)	12 34	11 92	11 33
Cod liver oil (millions of bottles)	3 28	3 30	2 79
Vitamins A and D (millions of packets)	1 03	1 03	0 83
Orange juice (millions of bottles)	15 58	14 81	13 41

These foods, she added, were intended for those whose diet might otherwise be deficient, and the arrangements of the local authorities were well adapted to concentrate attention on this group In the community as a whole the downward trend might well continue with the continuing improvement in the general diet and standard of living The department would maintain a close watch on developments

In England Now

A Running Commentary by Peripatetic Correspon

To conduct, control, and conclude a consultati a querulous, persistent patient is an exercise in ap personality that can be fascinating to the be although arousing different emotions in the p Medical students may study their chiefs and in outpatient departments the patients may fill their waiting time by making extensive observations on the subject I have had the good fortune to pursu subject *under both conditions and here* pres preliminary report

The commonest method, and one lacking all ch to terminate the interview and stop all further que is " I'll write to your doctor You go round and disc it with him next week " The psychiatrist, and those of psychiatric leanings have an altogether more diplom approach, an approach designed to act like foam o fire, to damp down and smother the burning pass and to allow those that will not be smothered to b themselves out These experts just let the pati on talking and talking while they remain emotio impassive, impersonal, and aloof At the end of allotted hour they quietly make an appointment fo further instalment, no doubt noting in their notes " Next Week " Another subtle, though somewhat approach is to appeal to the patient's self-esteem by *flattery This is often successful with readers of pop* medicine articles You merely have to preface y remarks with " A man with your knowledge of medi will at once realise " Another convenient for for the rushed doctor, but one liable to cause addict and even abuse by the lazy, is the " Let-me-know gets-any-worse " approach This is of course not f proof, for next week the patient may return to that it has become worse Under such conditions ano line must be taken. One may assure the patient t he has a very rare, interesting complaint for which yet there is no treatment (this is much favoured neurologists), one may keep them under observat (a physician's gambit), or one may adopt the " Th funny, *I have the same trouble myself*," and th unload your anxieties and symptoms upon the pat Oddly enough this seems to help both the patient *the doctor*

* * *

We are once again in the midst of an election batt with all parties in search of the elusive floating v and I am irresistably reminded of the last electi and Annie

Annie was one of several hundred old dears a home for the aged Never very active, she was confined to bed permanently with gangrene of foot, which she stubbornly refused to submit to surg She lay there in gloomy silence, and appeared to abandoned all interest in life

Which party it was, I forget, but some shrewd poli type saw in the home a happy hunting-ground for A fleet of cars arrived, and all those passed as " were taken to the poll. Annie pleaded for a ride, I hadn't the heart to refuse

On her return she was in a state of considerable tion " I do hope I done right—I suppose it's all for best " The old dear commented so seldom upon thing that such concern over the election was ext ordinary Sister investigated Annie was quite sure had just given consent for her leg to be amputated

I often wonder for whom she voted

* * *

As our taxi hurtled over the perilous track to Bab we found the driver glad to talk of life in his count We passed a convoy of army trucks given by the Un States and mobile A A guns made in England, then army camp Oh yes, there was national service, he s two years for all men—unless they paid 50 dinar which case it was three months That is official dinars secures complete exemption That is unoffi We skidded and slid in the sand, bumped, and th our way from one mud hollow to the next, and s smiled and joked. There was the way trucks are overloaded (nearly everyone we saw was an example) —When the last bus home was full the driver sent his colleague on to the roof among the luggage. But that night it was windy and cold so he shared a coffin with its rightful owner on his way to his burial When the next man came up on the roof the living occupant of the coffin put out his hand to show he was there He went to court—not for travelling with a corpse in a coffin but for putting out his hand in such a way as to frighten the newcomer Three months jail was the price of his thoughtlessness.

"We are living in the 10th century here our driver said as our 20th-century limousine survived mile after mile of insult. Wives are still cheap 50 dinars buys the ordinary kind 100 the very best If the husband does not like her he kills her She was no good ' in the law courts means no worse a penalty than two months in prison That is the law, you see." What happens if a man murders another man? we asked Oh he is hanged of course," he replied

Wives do the work while husbands sit in the cafés smoking their great ' hubble-bubble ' pipes. Toiling in the fields on either side of us through the hours of light were these poor peasant women heavily clothed in tattered black. There, too, were superb birds feeding in freedom Large green bee-eaters swooped on flying insects blackwinged stilts probed the saltings with their graceful bills a solitary flamingo stood still. 'If I d had the chance before I was born to choose what to be, I d be a bird, he said I see what he meant.

* * *

My peripatetic colleague surely cannot seriously intend that we should instruct our adult patients to Lie on the couch with your tummy upwards.' But I agree that the usual ' Lie on your back on the couch ' regularly results in a patient lying on his face The remedy came to me in a moment of inspiration: 'Lie down on the couch please. I say no more no less I have yet to see a patient who spontaneously adopts any but the supine position

* * *

Last year our rural district almanack and directory had some interesting health notes and hints for the nursery

" Headaches, dizziness and shortness of breath are often caused through neglecting the feet

"Cramp generally arises from a disordered liver For quick relief from the pain the feet should be plunged into hot water and rubbed hard with a towel. If hot water is not obtainable rub in camphor liniment or embrocation.

"If a person cannot sleep it is because blood is in the brain; the remedy therefore is to draw blood down from the head. This may be done by eating one or two small onions or a biscuit

"It is harmful to force a baby to take notice The brain will develop much better if left naturally

"Paddling in the sea is a serious danger to many children. Paddling has been known to cause convulsions, cramp heatstroke and severe bronchitis

Unfortunately the publisher seems to have had a hint that the notes are a little outdated for this year they have been replaced by notes on bird life and a page of wit and humour

* * *

In bed with another overpowering cold I am feverishly wondering why this type of coryza major never afflicted me until I came to British Columbia But here of course the forest trees are enormous, the buttercups grow twice as high as those in English meadows, and gigantic salmon throng the rivers. I ought to have known that the viruses would be jumbo size

* * *

Psychiatrists must look to their laurels, for it seems that their closed shop is not so closed as they think. In the last issue of *The Lancet* I read of kidneys showing "a diffuse distal tubular neurosis Imagination boggles at the future Are we to hear of neurotic syndromes relating to all histologically differentiated regions of the body? Sorry Old Man can't play golf today, I've neurosis of my islets of Langerhans

Letters to the Editor

BLOOD-AMMONIUM LEVELS IN LIVER DISEASE AND "HEPATIC COMA"

SIR,—In their article (April 23) Dr Phear Dr Sherlock, and Dr Summerskill have shown that the administration of ammonium chloride and methionine to two patients was followed by gross mental deterioration culminating in coma They state (p 838):

> As in case 1 *therapeutic* [my italics] administration of ammonium chloride caused the blood-ammonium level to rise before clinical deterioration took place and again recovery coincided with a fall in the blood-ammonium level. Following oral *dl* methionine a relapse was associated with a rise in the blood-ammonium level

The manner by which this information was obtained raises moral and ethical questions. No doubt the relationship between the level of blood-ammonium in liver disease and the production of mental changes is important to medicine. However, this information had already been obtained by other workers to whom reference was made in their opening paragraph (p 836) In order to prevent a premature or rash judgment on the moral issues involved would Dr Phear and her colleagues be good enough to answer the following queries

(1) Did they know that ammonium chloride and methionine were potentially dangerous to cases 1 and 2 before the drugs were administered? If they did why was it necessary to confirm the knowledge?

(2) Were the patients consulted *before substances* potentially dangerous to them were given and did they agree to participate in the experiments?

(3) If the patients did agree were they capable of fully *understanding* the nature of the therapeutic experiments and the dangers involved? From figs. 4 and 5 it would appear that they were not mentally normal before the noxious substances were administered

(4) If one of the patients had died in coma during the therapeutic trial would the coroner have been informed and given the full story?

(5) Would they have performed similar experiments on themselves or on their near and dear ones supposing they were clinically suitable?

Medical research workers who are concerned with human lives have to steer carefully between the production of fruitful work and the obligations of the Hippocratic oath In this spirit, I look forward to a satisfactory reply

Pathology Department,
Birmingham Accident Hospital　　S SEVITT

*** This letter has been shown to the authors of the article whose reply follows—ED L

We are glad to answer Dr Sevitt s points

1 Ammonium chloride (in the management of ascites) and methionine (on the nutritional hypothesis) are currently used therapeutic agents in the treatment of liver disease. Our paper concerns therapeutic trials *not* experiments Ammonium chloride and methionine were administered to these individual patients in order to diagnose accurately their mental and neurological illness. As we have concluded in this paper there is no certain biochemical method of diagnosis, and transitory mental and neurological deterioration *after* methionine ammonium chloride or a high protein diet are the only certain diagnostic tests we know Simple protein restriction is not a certain diagnostic method for we have observed patients with chronic portal systemic *encephalopathy* who have failed to respond to it. The diagnosis of these complications can be extremely difficult and later experience makes us think we may have over-simplified the issue in our earlier paper (*Lancet* 1954 ii 453) Certain diagnosis can of course be followed by correctly applied treatment *Trials* of this nature in patients with obscure mental and neurological illnesses will prevent many being admitted as certified insane to mental hospitals We have recently known of

six such instances We also give courses of ammonium chloride and methionine to candidates for porta caval anastomosis, where the development of mental or neurological changes contra indicates the operation It is unjustifiable to perform this operation without such a preliminary trial

2 The patients were aware of the nature of the substances they were to receive (they had had them before therapeutically in other hospitals), and that it was necessary for diagnosis to determine their effect They knew that temporary mental and neurological deterioration might follow, and willingly agreed

3 They were capable of understanding the nature of the trial

4 Under conditions of careful observation by the team here (which includes a full time trained psychiatrist alert to the earliest mental changes in liver disease), the possibility of permanent sequelæ or fatal issue due to these drugs is non existent The changes are transient and reversible The coroner would of course always be informed of unexpected death during any treatment

5 If we or our relatives suffered from liver disease and had mental changes or had an obscure organic psychosis or neurological illness it would be necessary, under hospital observation to determine the effect of nitrogenous substances including ammonium chloride and methionine

Dr Sevitt rightly emphasises the moral and ethical issues involved in our efforts to diagnose our patients' ills and in attempting to define more accurately the management best suited to their needs Like other members of our profession we are constantly guided by these moral obligations to patients who have sought our help or have been referred to us as difficult problems It was this moral obligation which prompted us to report our observations in the medical press and thereby draw attention to this complex and ill-understood aspect of liver disease This may provide guidance for others in the diagnosis and management of obscure organic psychoses, prevent unnecessary certification, and possibly prevent the present abuse of a high-protein diet and other nitrogenous substances in the treatment of liver diseases

We will be pleased to meet Dr Sevitt so that we can discuss the matter more fully and perhaps show him the clinical management of patients with liver disease in this hospital

INSTINCT AND THE NURSING COUPLE

SIR,—I would like to congratulate Dr Mavis Gunther on her interesting observations on nipple protractility, in her article of March 19, and to concur entirely when she says that, in human mothers, instinct does not ensure maternal efficiency in breast-feeding

This is perhaps made more obvious by the present day contrast between the high incidence of failure in the West and the almost universal success amongst tropical peasant mothers For example, in Yorubaland in Western Nigeria, of 208 children aged between one month and two years who were investigated, all were found to be still breast feeding successfully[1] Similarly, an as yet incomplete infant feeding survey in rural West Bengal has shown uneventful and continuous breast-feeding in all of over 150 infants aged between one month and thirty months so far investigated—with the exception of a small number where death or very severe illness of the mother made breast feeding absolutely *impossible* In both of these surveys, a high proportion of the nursing mothers were markedly malnourished

As to the factors suggested by Dr Gunther as being responsible for success or failure of breast feeding, I would offer the following comments and additions

(i) *Instinctive response*—This certainly appears to predominate in the infant rather than the mother, but the newborn baby will have more chance of successfully making contact if he is lying on a mat by the mother's side with the breasts near at hand, as occurs with the tropical villager

(ii) *Learning by observation*—From infancy Asian and African peasant females are surrounded by women unconcernedly and unashamedly breast feeding their children, not only in the house, but anywhere and at any time of the day or night

(iii) *Psychological factors*—The Western woman frequently approaches breast feeding not only in ignorance of practical details, but often with some, at least, of the following psychologically disturbing attitudes a fear of failure (engendered to some extent by modern old wives tales), a clear knowledge that easily accessible alternatives are available (which has been drummed into her since childhood by ubiquitous advertising), a desire to return to work or social life as soon as possible, and sometimes a dislike of the whole process or even in extreme cases an alleged disgust All of these can interfere with the mother's confidence and ability, so that, as stressed by Verhœstraete,[2] the disastrous snowball effect of worry—poor "let-down" reflex—dissatisfied baby—increased worry, &c occurs, associated with a diminishing output of milk from inadequate mammary emptying By contrast, the tropical peasant woman (and her Western cousin until quite recently) approaches breast-feeding not with confidence, because this is too positive a word, but a completely matter of fact naturalness Without being conscious of it she knows from personal observation that breast feeding is a simple process carried on uneventfully, while at the same time her attention has not, as yet, been distracted by the advertising of artificial foods In this context, it is interesting to note that, according to Cicely Williams (personal communication) European women, pregnant when interned by the Japanese, were later all able to breast feed their babies when faced with the uncompromising reality of a Singapore internment camp

(iv) *Shape of breasts*—Dr Gunther's investigation of nipple protractility is of great interest As far as I am aware no investigation of breast or nipple shape or size has been carried out amongst tropical peasant women My impression amongst West African women was that, possibly as a result of a lack of any type of support, the breasts were somewhat pendulous even before childbearing Certainly after the first baby the breast becomes flat in the upper half and rounded and pendulous below, presumably partly as a result of uncontested gravity, so that babies can easily be fed per axilla when carried on their mothers' backs In these women the nipple protractility should, one would have thought, have been excellent and have acted as a good "sign stimulus"

It is also interesting to note that the aboriginal Juangs of India divide female breasts into different groups according to their alleged milk giving potentialities[3]—from the *latop nunon*, which is flat like a tortoise and has a poor yield, to the *bagh nunoro* the rounded, so called "tiger breast" which is reputed to have an abundant and easy flow One wonders whether there may be some association in this classification with nipple protractility and ability to act as a "sign *stimulus*"

To close this short picture of the contrast between the over sophisticated Western mother and her counterpart in the tropical village, I cannot do better than quote Matthews's excellent description of the latter as seen in Nigeria

> "Her hormonal mechanism is undisturbed by anxiety complexes She is not besieged by friends, relatives, nurses and doctors advising her against breast feeding and putting her 'at the mercy of the accumulated gossip of her time' She does not receive, within a few days of confinement suggestive pamphlets from infant food manufacturers encouraging early weaning, nor is the Yoruba neurotically prejudiced against the nursing experience as being 'messy' and 'disgusting', nor does modesty prevent her feeding her baby in the markets, by the road side or, if she be a nurse, in the anteroom of the hospital ward What does she care if she lose her figure and her vein marked breasts sag over her umbilicus? Parenthood is her central interest, duty and pride"[4]

MEDICAL TELEVISION PROGRAMMES

SIR,—I protest against the programme shown on the B B C television service on May 2 Some elementary physiology was demonstrated with living subjects but the whole presentation was to me revolting At the point where a demonstrator actually burned with a lighted cigarette the forehead of a subject lying on a couch and connected with wires and tubes to recording gear, I switched the set off with the unanimous consent of my family Surely horror comics have nothing on this programme for pseudoscientific sadism

I hope there will be no more of this sort of stuff on television and that doctors will not coöperate in pandering to the crude public taste for medical sensationalism

Birmingham 15 FAUSET WELSH

HARDENED FATS AND LUNG CANCER

SIR —Dr Nyrop's further letter (April 23) erudite though it is should not be allowed to divert your readers from his original and quite unwarranted contention He has sought to show that a deficiency of essential fatty acids may be a factor in the causation of lung cancer and, more especially, that such a deficiency may be induced by the replacement of butter by margarine in the diet

Something may be said for the introduction of new theories of carcinogenesis, in that they may stimulate useful lines of investigation But as regards the essential fatty-acid content of margarine we are dealing with fact not theory The fact is that it has been shown by animal experiment[1] that margarine contains a substantially greater amount of biologically active essential fatty acids than butter Dietary deficiency in these substances whatever its rôle in carcinogenesis is therefore *less* likely to occur when margarine is eaten instead of butter

ELECTROPHORESIS OF PLASMA-PROTEINS

SIR,—In view of Dr J A Owen s letter of April 23 I feel I should point out that results of a rather similar nature have also been observed in these laboratories details of which will shortly be published in the *Journal of Clinical Pathology* There are, however some points upon which I would like to comment

We do not obtain such distinct double β globulin bands as is illustrated by (*a*) in Dr Owen's letter, unless the serum or plasma is fresh and unless the buffer contains borate Dr Owen s result, in the absence of borate appears to be the exception rather than the rule as is evident from the great majority of published illustrations of paper electrophoresis of sera in Veronal buffer

The reason for the occasional exception is not at present clear; we confirm that the slower β globulin component is undoubtedly labile as it disappears after serum has been allowed to stand at room temperature for several hours or even after storing at −20°C for two weeks. Borate appears to exert a stabilising effect in electrophoresis, but in the absence of borate there may be other factors in Dr Owen s experimental condition which also prevent alteration of the labile component. Contrary to Dr Owen our results suggest that the labile component is converted in aged serum to one of higher mobility and merges with the normal faster β-globulin band.

In his second illustration (*b*) there is also shown a double β band, but in this case the slower component is absent and a band appears just ahead of the normal β band We suggest that this faster component is an artefact produced presumably by enzyme action on one of the β globulins since we have obtained similar results only with sera which have been aged at room temperature for long periods

Alterations in the ratio of the concentration of the two β globulin components in fresh serum or plasma may well be significant in some diseases but it is clearly important that no appreciable alteration to the unstable component should occur during electrophoresis One method would appear to be the use of borate, but in borate alone α_1 globulin has a mobility similar to that of albumin This disadvantage has been overcome by employing a mixed borate veronal buffer, which is now being used in these laboratories for routine investigation Full details will be published in the forthcoming paper

A MORPHOLOGICAL CRITIQUE OF TEMPORAL LOBECTOMY

SIR,—In his article (April 30) Dr Crome expresses doubts regarding the validity of the biopsy findings reported, among others in a paper by myself in collaboration with Mr Murray Falconer and Mrs Elizabeth Beck.[1]

In this paper we discussed rather fully the difficulties inherent in the interpretation of biopsy material, and we had taken care to reduce the element of ' subjectivity by controlled serial investigations We also admitted to being inevitably handicapped by not knowing whether similar changes are found in the unoperated temporal lobe or in other parts of the brain In our conclusions which were mainly concerned with ætiological problems, we stressed the preliminary nature of our report and the importance of systematic post-mortem studies of clinically and electrophysiologically well investigated cases of temporal lobe epilepsy as ' they are bound to give a more comprehensive and clearer picture of the histological changes than the investigations of isolated biopsy specimens so difficult to interpret could ever provide '

Such post mortem studies on an adequate scale will naturally take some time to mature Dr Crome s otherwise important and interesting material is deficient in this respect since on his own admission no reliable information could be obtained on psychomotor phenomena hallucinations, and auras owing to the severe mental retardation in the majority of his cases.

The histological abnormalities in our material of 18 cases were severe in 11 consisting either of focal lesions (circumscribed tumours and vascular malformations) or of diffuse cortical and white matter sclerosis Partly overlapping with these cases Ammon s horn sclerosis was found in 7 (not 5 as Dr Crome stated) out of 12 cases in which hippocampal tissue was available for study Dr Crome dismisses Ammon's horn sclerosis as a merely secondary phenomenon due to severe grand mal or other types of anoxia. Although we agree with this view (as we have been at pains to point out in our paper) this does not preclude its primary significance in the clinical manifestations of temporal lobe epilepsy Evidence has been accumulating particularly from experimental studies that Ammon s horn and the neighbouring uncus and amygdaloid complex serve general visceral function and have some relation to behaviour particularly emotional behaviour Their pathology in cases of temporal lobe epilepsy requires, therefore our earnest consideration

In only 4 of the 18 cases doubtful and uncertain pathological changes predominated although even in these some positive findings were recorded There is thus in our material considerable variation of the pathological changes both in quality and quantity as we stated in our paper Should these be causally related to the clinical manifestations of temporal lobe epilepsy this relationship would not be a simple one Perhaps we did *not* sufficiently emphasise this complexity in our preliminary communication but it has been given attention in our more recent publication[2] in which we discussed the possible significance of a genetically determined epileptic factor and of an unspecific effect of the operation by removal of not necessarily diseased centres and interruption of neuronal pathways responsible for the seizure In focusing attention on the complexity of the problem Dr Crome s paper has been very helpful.

CIVIL SERVICE MEDICAL APPOINTMENTS

SIR,—It was with the gravest disquietude that I read the recent advertisements in *The Lancet* to recruit doctors to posts within the Civil Service

Perhaps the most glaring anomaly in these advertisements is the statement that there are "promotion prospects," this statement appearing with surprising regularity in every post that is offered This would indeed be a welcome change of heart if it were so, but when the Treasury evidence to the Royal Commission in relation to the claims of the Civil Service doctors is studied the statement becomes ludicrous

Perhaps the intending applicant has not yet studied this evidence, which indicates fairly forcibly the poor opinion the Treasury holds of us doctors in the Civil Service, and they are the people who count when the question of numbers and remuneration of higher posts is under consideration

The additional information given to candidates with the application forms is no more informative regarding these "promotion prospects" A small paragraph states quite simply that certain grades exist, but it does not mention what we all know—that all these posts are filled and any promotion is unlikely in the foreseeable future

It appears to me that this should be made known to intending applicants, for the impression given by the advertisements is far removed from the situation as we know it

TOAD BENEATH THE HARROW

A LIVER POISON WITH UNUSUAL PROPERTIES

SIR,—I have read with interest the letter on icterogenin by Professor Rimington in your issue of April 9, and I am sorry that I did not know of his isolation of the lippia poison when I wrote my first letter I am glad to hear that studies of the icterogenic properties of this remarkable substance are already planned May I suggest some points which I feel are of special importance in further studies with icterogenin?

Firstly, it seems to me important to decide whether icterogenin jaundice be a retention jaundice or a lymphogenous jaundice The poison may act in one of two ways (or perhaps in both of them) (1) by paralysing the bile-pigment excretion through the parenchymal liver cells, and (2) by reversing the secretion of these cells from the normal pathway (blood to bile capillaries) to an abnormal pathway (blood to lymph capillaries) [1,2a]

This may be decided experimentally by collecting the liver lymph (or thoracic duct lymph) during icterogenin poisoning and determining the concentration of bile pigment at different times and comparing it with that in the serum If the possibility (1) is correct a prompt direct diazo reaction in the serum (which is found in lippia poisoning) occurs without the bilirubin having passed the liver cells, and if (2) is correct the existence of a secondary secretory mechanism as pathogenesis of lymphogenous jaundice is proved [1,2a]

If (1) is correct our concepts of retention jaundice must be altered Up to the present our knowledge of experimental retention jaundice has been gained exclusively from studies on partial and complete removal of the liver—a technique which is far from ideal because the removal of the liver is followed by important changes in many vital functions and especially because bile pigment production in the stellate cells of Kupffer, which seems to form the bulk of the bile pigment in higher animals,[2b] is abolished

In this respect it is important to remember that the jaundice of acute yellow atrophy of the liver is accompanied by prompt direct diazo reaction [2c] In this condition all parenchymal liver cells must be considered necrotic or at least completely inactive, while the stellate cells of the liver are relatively unimpaired [2d], so the jaundice in acute yellow atrophy seems to come close to a pure retention jaundice, and thus to be very similar to icterogenin jaundice if possibility (1) is correct. As the two conditions have the prompt direct diazo reaction (van den Bergh) in common, (1) cannot be excluded beforehand

If possibility (1) be correct our theory of jaundice must be altered because, according to current concepts, retention jaundice can only become intense after several days [2e], and this cannot be so if lippia jaundice is a pure retention jaundice, because it reaches high intensity in two to three days Perhaps the high bilirubin levels in occlusive and parenchymal jaundice may be explained by retention without regurgitation or other forms of lymphogenous return of bile pigments to the blood.

Secondly, studies in as many species as possible including both laboratory and farm animals and birds, and, if feasible, volunteers, are highly desirable

County Hospital,
Svendborg, Denmark. TORBEN K WITH.

ENURESIS

SIR,—This correspondence and a sentence in your leading article of Feb 19 ("We are not so well equipped to treat enuresis that we can ignore any promising technique") prompts me to write of some conclusions I have formed from twenty years of dealing, in the main successfully, with enuresis in children

Does not the cause of our lack of success lie in the tendency for the specialist to treat enuresis as a phenomenon of the urinary system alone, and for the general practitioner to take the opposite line and tell the mother that the child needs no help and will "grow out of it"?

It is, of course, true, as you state, that in a certain proportion of children the situation arises from specific pathological conditions of the urinary system, but these cases amount to a very small proportion of those suffering from this very common complaint Elaborate urinary investigations, on the other hand, tend directly to increase the child's difficulties in gaining control, and to hinder the achievement of understanding by physician, mother, and child of the part played by delayed bladder control in any individual child

Surely the kernel of the whole problem lies in the power of the body to use its normal functions both to side-track and express emotional strains?

Do we not all remember the frequency of our visits to the W C while waiting for *viva voce* examinations, and have we not noticed how the frequency and timing of micturition in ourselves varies with the weather and the emotional significance of the day's programme?

This ability of the bladder to respond to factors affecting the whole personality is much more marked in children than in adults There is, also, an aspect of urinary performance additional to the emotional factors described by other correspondents, which is peculiar to children

The adult is used to himself and his physical apparatus he has, alas, in most instances, long ceased to "play," and his excreting organs are only of passing interest to him. On the other hand, in children, curiosity, the desire to experiment, the enjoyment of "play," and the urge to acquire knowledge of himself and his functions, and of the mysterious lacks in his small sisters, leads to a concentration of interest on his excreting organ which can be overlaid with other activities during the day, but returns with full force when these vanish in sleep Then, the child who is disturbed in his personality, as described by Dr Symonds (Feb 26) and who has insufficient opportunity and/or ability to "make friends" with the varied aspects of himself, and to gain release from tension in play, will use his urinary function to achieve this end in sleep

---

1. With T K *Acta med scand* 1947 128, 25
2. With, T K Biology of Bile Pigments Copenhagen 1954, a, pp 113, 122 b p 61 c, p 201, d, p 63, e, p 121

It is not the bladder or its controlling mechanism but the ole child who needs investigation and help

The difficulty in the treatment of enuresis arises from the paration between pædiatrics and child psychiatry so at the pædiatrician too often sees only the function and e psychiatrist only the personality and such common ro factors as maturation opportunities for play and nsible education of the mother in understanding both des of her child s nature so often do not appear at all

It has been our custom in our treatment at the Institute Child Psychology to provide a ground floor room with cement floor sloping to the outside with illumination from waterproof ship side lantern which is fitted with sinks at fferent heights, water toys of all sorts and pots and jars d hose-pipes. Here clothed in wellingtons and mackintosh child can work out in real water the drives fantasies and periments and—with the aid of the therapist—clarify e puzzles which lurk in his mind and perhaps tip the balance wards expression of all these through his own water reserves night

As Dr Jackson (April 16 p 822) has so wisely pointed ut, rate of maturation varies enormously in different ildren (though surely he is incorrect in putting the lower mit for bladder control at three years ?) and giving up e desire for elementary water play is a function of aturation.

London W 11
MARGARET LOWENFELD

THE DIFFICULT APPENDIX

SIR,—Mr Kerr ends his interesting article of April 9 with the sentence I have regarded McBurney s point as ½ in. below the midpoint of the line joining the umbilicus to the right anterior superior iliac spine.

This implies that there is some choice as to where McBurney's point may be placed This is not true as is shown by the following quotation from McBurney s original paper [1]

> And I believe that in every case the seat of greatest pain *determined by the pressure of one finger* [italics by the author] has been very exactly between an inch and a half and two inches from the anterior spinous process of the ilium on a straight line drawn from that process to the umbilicus. This may appear to be an affectation of accuracy but, so far as my experience goes the observation is correct.

An asterisk after this sentence points to a footnote which reads as follows:

> “Since reading this paper I have carefully observed three other cases. In two the point of pain shown by pressure with one finger was two inches and in the other an inch and seven-eighths from the anterior spine

George Washington University
Medical School Washington D.C.
ALEC HORWITZ

CHRONIC SYSTEMIC LUPUS ERYTHEMATOSUS

SIR,—Your valuable leading article of April 16 prompts me to report 2 cases I have seen recently

A woman of 45 was admitted to hospital in November 1953 with pneumonia. She had had four attacks and a rheumatoid arthritis during the previous six years. She was found to have bilateral basal bronchopneumonia a rheumatoid form of arthritis, enlarged glands in the right axilla and scleroderma of the hands Hb was 48%. The serum albumin/globulin ratio was reversed and L.E. cells were found in the blood smear Pyrexia persisted for weeks despite treatment with antibiotics. There was an immediate remarkable response to corticotrophin. Pyrexia ceased and expectoration of sputum stopped with astonishing rapidity This patient was discharged on 50 mg. of cortisone daily but later the kidneys were involved with albuminuria and uræmia and she died about a year after discharge

A man of 49 was admitted to hospital in June 1954 following five to six weeks of diarrhœa, with blood and mucus in the stools, and painful swelling of both legs Similar attacks of diarrhœa and pain and swelling in the legs had occurred at intervals for the past five years. He had had many attacks of episcleritis in the previous ten years. He had low fever episcleritis in the left eye cellulitis of the left leg and an anal fissure A barium enema showed appearances typical of ulcerative colitis Hb was 75%. Serum proteins were within normal limits. L.E. cells were found in the blood-smear Treatment with corticotrophin was started a month after admission. The pyrexia ceased within a few days and the diarrhœa stopped with astonishing rapidity The anal fissure healed shortly thereafter This man is out and about on 50 mg cortisone daily

These 2 cases represent a chronic form of systemic lupus erythematosus which appears to be commoner than its acute manifestations [1] Both presented without superficial skin lesions or albuminuria The clue to diagnosis in such cases seems to be recognition of the association of recurrent febrile illnesses such as pneumonia pleurisy, pericarditis conjunctivitis colitis &c with involvement of other systems notably the joints and lymph glands. Examination of the blood for L.E cells may be unexpectedly helpful

North Middlesex Hospital
London N 18
D FERRIMAN

CORPORAL PUNISHMENT IN SCHOOL

SIR —The question of corporal punishment in school and the principle underlying it should be decided on the rational ground whether it is favourable or not to the health of children in general As I see it this is a crucial and pressing issue not perhaps especially for doctors but for any society seriously concerned with the health of its children Perhaps therefore you will allow me to make some points on this question

The parent who nags his child to “ concentrate who censures him for incontinence or thrashes him for pilfering is in the same boat with the teacher who cuffs his pupil for not attending to the board or for adding 2 and 3 to make 11 They are behaving exactly like the mechanist philosopher who by tradition has explained learning in terms of the law of use and the pain pleasure principle The former was based on the idea that repeated stimulation of a sensory nerve facilitated a muscle response the latter that pain inhibited and pleasure facilitated a muscle response

In the last half century the *Gestalt* scientists have produced an overwhelming mass of evidence against a mechanistic explanation of natural processes. They have established that the behaviour of living organisms is governed by the laws of organisation and they use the word insightful ” to characterise the behaviour of all conscious organisms. Let anyone reflect whether a child has ever learned to be generous to control his bladder to solve a problem in mathematics to use crayon, brush, or tool through pain or fear or insightless drill In fact all these abilities are functions of the maturation and differentiation of the brain muscle gland organisation and the insight that depends on them.

That physiological processes like the maintenance of the acid base balance and of the constancy of the internal temperature are organised processes justifies Cannon s use of the phrase the wisdom of the body Cannon has further shown that when an animal is affected by *any* painful situation it mobilises its energy for muscle action designed to relieve the stress and restore the animal s balance and unity *Pain is* thus not a deterrent but a positive incitor to action on the part of an organised being like an animal or child It is stress demanding resolution in action.

I consider that sexual tension grows out of ” emotional tension in general and it is therefore easy to understand the two way traffic between sexual and any other kind of emotional tension I have known a child in whom masochistic behaviour had been evoked in infancy flee from punishment in school as from mortal danger and I have seen a hysterical reaction provoked in a teen-age girl at the mere witnessing of the punishment of other children. Any mode of education which uses punishment as a tool establishes a sado masochistic relationship between child and parent on the one hand and pupil and teacher on the other which will colour the child s whole life

But further the unremitting punitive *tensions* in home and in school to which children are subjected in certain areas are in my opinion a decisive *factor in the production of* serious physical illness. If, as I believe resistance is a condition of energy of the child as a whole then punishment will render him susceptible to illness by lowering his resistance

---

[1] McBurney C N Y med J 1889 50 676

[1] Tumulty P A J Amer med Ass 1954 156 947

The analysts maintain that the child can "adapt" by using the punitive tensions of authority to build up his super ego and other internal forces of resistance He will then become a "good" person But he will externalise his "unconscious sense of guilt" and many such individuals are always "looking for something to forbid" and cannot even observe the natural behaviour of children without experiencing an inner compulsion to lay hands on them It is not surprising that analysis is confronted with the paradoxical situation of having to restore to broken lives the unity that they possessed in the beginning

Finally, what moral argument is there on behalf of punishment or the "threat of the withdrawal of love" as an instrument of education? As Kenneth Walker says in his *Sex and Society* "It is a betrayal of every spiritual value we profess to hold in reverence, to use love as a bait or a weapon of coercion"

A VISIT TO KOLTUSHI

SIR,—I found the article by Mr Ruscoe Clarke and Dr Leonard Crome (April 2) most interesting Of interest, too, were the comments of last week of Dr Mungo Douglas in that they represent a distaste for Pavlov's work which is by no means unusual in the British profession

However, one cannot but contrast the meticulous objectivity of the Pavlov school with the doctrinaire disregard of facts shown by Dr Mungo Douglas Instead of criticising the experimental findings, quoted by Mr Clarke and Dr Crome, he asks the rhetorical question "Is it a study likely to provide the kind of future we should all desire ?"

If it can be shown that the great mass of data accumulated by the Pavlov school is all wrong, or if it can be shown that these facts are without relevance to, for example, gastric function, bronchospasm, or, as suggested by Pavlov, schizophrenia, then it is open to Dr Mungo Douglas to prove his case But, in the scientific world at least, generalisations about vital freedom and enslavement cannot be accepted as a substitute for the dispassionate consideration of established facts

Personally I welcome all facts relating to conditioned reflexes since they touch on some very fundamental problems and suggest some interesting possibilities in clinical application

Sheffield C H FOGGITT

PSORIASIS SPONDYLITICA

SIR,—Dr Lydon (April 30) asks us to support the unitarian theory of the pathogenesis of the rheumatic diseases This concept has, however, in the past, proved unhelpful in furthering our understanding of these disorders of connective tissue Moreover, as Professor Kellgren has pointed out,[1] just as no sensible person would seriously suggest that all diseases of the nervous system have a single ætiological factor, so it is equally unlikely in the case of the diseases of the supporting structures It is probable that research into the fundamental cause or causes of the rheumatic diseases will be easier once a greater knowledge of the normal anatomy and physiology of connective tissue and of the various clinicopathological entities which we call the rheumatic diseases has been acquired

As the expression of a useful piece of clinical observation, I, for one welcome the term "psoriasis spondylitica" used by Dr Fletcher and Dr Rose (April 2)

One other point arises from Dr Lydon's letter he is incorrect in regarding the arthritis of Reiter's disease as indistinguishable from rheumatoid arthritis—it differs from it in the joint "pattern" and in its course Reiter's arthritis predominantly affects the joints of the lower limbs, especially the knees and the ankles, it is also much more benign, and seldom leaves any permanent crippling deformities except in the feet

London W 1 J F BUCHAN

NON-PROGRESSIVE BREAST CANCERS

SIR,—Further evidence of the common occurrence of non-progressive, non lethal lesions, in general indistinguishable microscopically from lethal breast cancer, appears to be requisite for a fuller realisation or acceptance of the limitations of treatment Such evidence is obvious, I think, in the data of two series of cases cited previously[1] and other related data In one series, stage 1 (i e, confined to breast) constituted 50%, the 5 year survival-rate in the whole series was over 60%, and in the stage 1 cases it was 85 6% In the other series the respective figures were 16%, 43%, and 81% Consideration of all factors left no reasonable alternative to the deduction that the majority of stage 1 cancers in the first series were non-progressive lesions, and that they accounted, though not necessarily exclusively, for the unusually high 5 year survival rate for the whole series and largely accounted for the high 85 6% rate in the stage 1 cases The near equality of 85 6% and 81%, and the similarity of both with the rates usually obtained in stage-1 cases, point to similarity in the material providing these rates In other words, as the majority of the stage 1 forming 50% in the one series appeared to be non progressive lesions, it seems a reasonable deduction from the similarity of the survival-rates that the majority of stage-1 cancers in most series are similarly non progressive lesions The high proportion of non progressive lesions in the stage-1 cases could then explain, reasonably and consistently, the high survival rates in the latter In contrast to the contention that stage 1 lesions are progressive lethal cancers in an early and curable stage of development, this explanation is fully compatible with the persistence of level trends in age specific mortality in spite of an increase in stage 1 in the treated cases, compatible, too, with the wide variations in reported survival-rates in different series, and with frequencies of stage 1 and of grade 1 as found at different durations.

This does not imply that all the difficulties of differentiation are confined to stage 1 cases The wide difference in survival time even in well advanced cancer, both untreated and treated, reflects wide difference in the degree of malignancy in such cases That difference is not fully revealed even with grading of tumours by microscopy Lewison, in the Halsted Clinic, carefully re-examined sections from the tumours of patients who had survived ten years or more but found nothing on which to prognosticate the long survival[2] Marley et al found approximately the same five and ten year survival rates in cases *clinically stage 1 but pathologically stage 2 (axillary involvement)* as in cases clinically stage 1 but pathologically stage 1 The rates lay between those in *stage 1 and those in stage 2 (clinically and pathologically)*[3] While the near equality of the survival rates in the two groups could be due to chance, it may indicate a degree of distribution of malignancy somewhat representative of such cases as those described An unidentified increase in such *clinically stage 1 but pathologically stage 2* cases in series treated in successive quinquennial periods could thus be a factor in the progressive increase in survival rates in the cases with *axillary involvement as reported* by several clinics

As Smithers et al. have emphasised[4] survival rates are influenced by factors other than diagnosis and differentiation, such as difference in selection of cases after diagnosis, in staging criteria and their application, in detection of lymph-node involvement, in follow up, in calculation of survival rates, &c. However, when, in fifteen series of different time or place and for which the necessary data were available, the 5-year survivals of stage 1 were deducted from the over all 5-year survivals, the net 5 year survival rates then ranged from about 10% to about 30%, with the majority close to 20% They thus approximated to what might be found in untreated lethal cancers. This suggests that the content of non progressive lesions, as stage-1 cancers, is the most potent factor distorting survival rates and suggests also that the varying inclusion of such lesions accounts for most of the difference between survival rates of untreated and treated cases as well as between the rates of treated cases

---

[1] *Lancet* 1954, i, 251
[2] *J Amer med Ass* 1953, 153, 905
[3] *Brit med J* 1953 ii, 787
[4] *Brit J Radiol* 1952, suppl no 4

These points are fully consistent with evidence previously reviewed , fully compatible, too with the findings of Murley et al. that all different treatments gave the same survival rates,[5] and also with the findings of Small and Dutton that some patients with treated breast cancer die at normal rates and others die at increased rates that " mortality in cancers is a constant process, little affected by treatment " and that 'it is doubtful if many more persons are cured by radical mastectomy than by other forms of treatment [6] The deductions or suggestions here really go little beyond what is already well recognised and is implicit in all the efforts that are being made to find a sounder basis for prognosis than microscopy provides.

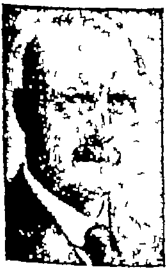
Obituary

HUGH ALLAN MACEWEN

O.B.E. M.B Glasg , D.P H. F R.S.E.

Dr Hugh Macewen a former senior medical officer of the Ministry of Health, died at his home at Innellan, Argyllshire, on April 17

He was a son of Sir William Macewen professor of surgery in Glasgow University He entered the same university and graduated M.B in 1905 He early decided to specialise in public health, taking the D P H of Cambridge and of the London conjoint board in the following year He gained experience as assistant M.O H of Cumberland and M.O H of Fife and Kinross, and later visited the United States, where he was lecturer on hygiene at Cooper Medical College, San Francisco To this period belong his excellent manual on *Food Inspection* his account of *The Public Milk Supply* and his investigations into conveyance of whooping-cough from man to animals by direct experiment



Elliott & Fry

When Macewen was appointed a medical inspector of the Local Government Board Sir Arthur Newsholme then the medical officer of the board lost no time in employing him in important investigations He worked at first in the foods branch and then chiefly directed his attention to epidemiology His *Report on the Prevalence of Poliomyelitis in Certain Districts of Lancashire and Westmorland* (1914) confirmed the views of Wickman Reece, and others that the disease was spread by contact infection

During the first world war Macewen acted as one of the liaison officers between the War Office and the board in the inspection of military camps and hospitals in England and Wales and he was appointed O B E for his services. He became a medical officer of the Ministry of Health in 1919 From then onwards he was chiefly employed in medical administrative work at headquarters. His immediate chief was Colonel R J Reece the epidemiologist, for whom he had a warm friendship Macewen s abilities soon marked him out for promotion and a few years after the establishment of the Ministry he became senior medical officer of the branch of sanitary administration in relation to infectious disease With the passing of the Local Government Act in 1929 the Ministry became concerned with the new municipal hospitals and their efficiency and Macewen was appointed the senior medical officer of the branch which dealt with public health surveys, hospitals, and public-assistance medical services. This work he directed with his usual thoroughness and success. He was in charge of the special investigation into maternal mortality which was published as a white-paper by the Ministry of Health in 1937 In this inquiry his wife, Dr Barbara Cunningham O B E., took an important share. In the early years of the second world war he was in charge of the regional medical organisation, and it was once said that even the evacuation scheme for expectant mothers could not remove the smile from his face

In 1941 Macewen retired from the Ministry but not from medical practice He became medical superintendent of Ballochmyle Hospital in Ayrshire and acted for a time as M.O H of Ulverston rural and urban district in North Lancashire

As a senior medical officer at the Ministry in the 'twenties and thirties he came into close contact with the medical officers of the large local authorities, and as the years went by he came to be more and more trusted by them. Many became his personal friends and one of them, W M F , writes 'Macewen showed his devotion to the cause of public health in everything he undertook. Despite the clinical atmosphere in which he was brought up, as the son of Sir William Macewen, he was convinced of the supreme importance of preventive medicine Before he began his long and successful career at the Local Government Board and at the Ministry of Health he was a medical officer of health and after his retirement, he became—temporarily—a medical officer of health again. To him and his colleagues at the Ministry we owe the rapid development of the personal health and hospital services during the twenty-one years between the first and second world wars. He possessed to an unusual degree the characteristic of selflessness Though he rose to a senior position at the Ministry it was impossible to detect in him any signs of overweening ambition Incapable of jealousy for himself he was jealous of the reputation of the English public health service '

A. S MacN writes Hugh Macewen was a man whose life and work were dominated by high ideals, and his sense of duty and devotion to the public weal never wavered He was serious in disposition except on social occasions when he would unbend and reveal a sense of humour He retained his Scottish accent, was outspoken in his beliefs and while just and considerate to his medical officers, demanded and obtained the best from them Much of his valuable work for the Local Government Board and the Ministry of Health is to be found in official files reports, and blue-books, and in all he did he worthily maintained the high standards and traditions of the central health department "

A colleague at the Ministry of Health writes Around 1930 a number of medical officers entering the Ministry were lucky in having Hugh Macewen for their chief and mentor The formidable exterior soon revealed beneath it a real kindness, a devotion to duty and a passion for accuracy which would never tolerate slapdash work. Verify your references —in the widest sense—might have been his watchword The department lost something of the old traditions and standards of the Local Government Board when he left, though he was able to do excellent work in Scotland both during and after the war He finished a fine life beside his beloved Clyde

HORACE BRYDEN HILL

M.B. Lond M R.C.P

Dr Horace Hill, medical superintendent of Laverstock House Salisbury who died on April 25 at the age of 70 was a man of considerable versatility

After qualifying from St Bartholomew s Hospital in 1901 he held house-appointments at Barts and at Huntingdon County Hospital In 1907 he took the M B Lond., and about this time he joined the Royal Navy and became a member of the staff of the Royal Naval Hospital at Haslar He had always been an all round athlete : an international hockey player and a member of the United Services cricket XI he also took a keen interest in boxing and played water polo This background led to his appointment to the staff of the Naval school for physical training at Portsmouth and later he became instructor in physical training at the Royal Naval College, Osborne In 1911 he took the M R C P

---

[6] J Amer med Ass 1955 157 216

During the 1914–18 war he served as a medical officer in H M S *Highflyer* He was made knight in the Order of St John of Jerusalem for his reorganisation of the training and service conditions of the Royal Naval Auxiliary Sick Berth Staff Reserve He also collaborated with Naval officers in an investigation of the best method of applying discipline in the Royal Navy He was made a chevalier of the Order of the Crown of Italy for his work in the Messina earthquake

After the war he left the Navy and settled in practice in Harley Street, joining the staff of the Royal Chest Hospital, City Road He was a vice-president of the Medical Defence Union In 1930 he published a handbook for students on *Electrocardiography* In 1936 he became medical superintendent at Laverstock House His later publications reflected his responsibilities and interests in this new appointment In his brochure in the *Public Attitude towards Mental Disease* (1939) he pointed out how desirable it was that relatives should not delay in seeking early treatment for a patient He also published a useful little book on safeguards in certifying those of unsound mind, and a more formal treatise on *Histamine and Insulin Treatment of Schizophrenia* (1940)

He was no mean painter, and some of his paintings hang in the Royal Fowey Yacht Club where he used to spend much of his leisure His widow survives him

DAVID WINN HOODLESS

O B E , B Sc Lond , L M S S A

WHEN Dr Hoodless was appointed the first principal of the Central Medical School in Fiji in 1929, he was already known, loved, and respected in the Pacific, for he had spent almost twenty years in the Colony as a schoolmaster and later as its director of education

Though his father was an engineer Hoodless came of farming stock He was born in 1887 in a small village in Nottinghamshire, and was educated at Sheffield and at King's College, London, where he gained a gold medal for mathematics, graduating B SC with honours in 1910 His first post as a teacher was in the training ship H M S *Worcester*, where he specialised in mathematics and navigation Two years later he went to Fiji as headmaster of a school for native boys, and later of the Queen Victoria School at Suva Through his work he came into close contact with the Fijian people, and his wish to serve them turned his thoughts to medicine In 1919 he came to England for two years to study at Charing Cross Hospital In 1921 he returned to the Pacific as inspector of schools in Fiji, and the following year he was appointed director of education During the five years that he held this post he established five new provincial schools to serve the Indian as well as the Fijian communities and started a scheme for recruiting teachers from New Zealand Such was his determination that he returned to England in 1928 to continue his medical studies, but illness prevented him from taking his finals in 1929 Despite his lack of formal medical qualifications he was wisely appointed the first principal of the Central Medical School When he qualified in 1935 he also took the diploma of tropical medicine

Hoodless did his task in Fiji so well that he was sent to inspect medical schools in Africa, but when the war broke out in 1939 he was recalled as he was indispensable to the Fijian government On his retirement in 1947 he was appointed O B E He was an associate of King's College In 1953 he became correspondent to *The Times* in Fiji

P M-B writes "The name of Hoodless was one to conjure with in the Pacific He probably did more for medicine and education in Fiji than almost any other man He was the moving force behind the Central Medical School for Polynesians in Suva, and it must have been a great satisfaction to him when two years ago the Queen opened the fine hostel for Polynesians and the ancillary teaching blocks at the school An even greater satisfaction to him was the renown which the graduates of his school won from so many quarters during the late war Many of the Allies, mostly the Americans, were amazed at the knowledge and efficiency shown on many a lonely Pacific atoll by the Polynesian doctors who had been educated in Suva It was the greatest compliment to him that the American government for the island of Guam and the New Guinea government sent their quota of medical students to Suva Throughout the myriad islands of the Pacific he will be mourned as the guide, philosopher, and friend of the Polynesians, for he not only taught but guided and advised them as the ideal leader of their youth "

Dr Hoodless married in 1923 Miss Hilda Adlington, and there is a daughter of the marriage He was on holiday in this country with his wife when he was taken ill in Cambridge He died on April 15

Dr EGBERT MORLAND

S T writes Egbert Morland was a connoisseur of "obits" Not for him the list of dates and appointments culled from the reference books Every obit must stand on its own merits To write dully about the dull was a sin against the craft of journalism The ethic of happy curiosity, which he professed, made him certain that no life could be so barren as to yield nothing of interest and it was the thing of interest alone which was worth recording But a good obit must not only interest, it must entertain, amuse, or edify It must tell the truth without unduly offending the relatives It must please friends and pacify enemies It must follow no logical pattern, but must blend fact and interpretation into a whole, having an artistic integrity of its own And if on reading it, our eyes are filled with that divine mixture of laughter and tears, then it may be said to have succeeded

Egbert's attitude to obits followed from his rational Christian view of death Dying might be very unpleasant but death was a brief moment of transition only and the gateway to another "awfully big adventure" He saw no reason to doubt the spiritual validity of Christ's promise of immortality So when those we know or love come to die, selfish sorrow at our loss should deliberately be replaced by joy at their good fortune For Egbert, the conventional condolences and the trappings of mortality were a source of endless delight and amusement

I think Egbert was a Benthamite, a pragmatic utilitarian, to whom happiness was very important indeed He wanted everybody to be happy, and saw no reason why he should not begin with himself

Despite an occasional witticism at the expense of reformers, he was a reformer himself He was seeking ever to make the world happier, wiser, and more amusing He was not always sure of the precise course to follow, but he turned this multivalence to positive advantage He would back people rather than plans Having picked his men or women, he would test them and try them with every devious tortuosity he could devise If they still came up smiling, or at least came up, he would give them their head At times, indeed, his trust was almost alarming So we of his staff were able to become once again "those sharp *Lancet* fellows" who had fought the good fight a hundred years before

Arrogance as a cloak for ignorance he would not tolerate Indeed the puncture of pomposity was a favourite occupation There was no subject on which he was ashamed to confess that he did not know, and he expected a like humility in others He had no patience with the establishment of a committee as an excuse for inaction, and his gentle ruthlessness was often an unpleasant surprise to the "No" men of his day

It would be incorrect to say that the truth was not in him But sometimes it took a lot of finding "Always remember," he told me, "that in journalism interest is more important than accuracy" He held the view that the only purpose of writing was to be read If this failed then the whole thing became a sterile intellectual exercise For the same reason, he loved the stimulating or provocative headline, the carminative which tempted the lazy appetite into operation The right place for the purely descriptive heading was the abstracting journal

Egbert's insight into his tortuosity was complete "Whether I have continued to edit *The Lancet* or become an inmate of Brixton has rested upon a knife-edge A single tiny genetic alteration and the coin might have come down the other way I hope I am enough of a knave not to be a fool"

As the years rolled by, his obliquities became more oblique and the knight's moves of his mind took on an ever more fanciful pattern "I cannot solve your problems, my dear fellow at best, and even this is improbable, I may perhaps enable you to solve them for yourself" We were talking under a mighty tree in an Aylesbury garden and I left him with none of my conflicts resolved Yet over the months they melted away as perhaps he intended they should. Years before, when I had been tortured by doubts he had joyously put me on the right road when he finally saw he saw with great clarity

Dear Egbert to have worked for you and with you was a joy which time dims not at all To skip and picnic again with you and Mary in the Elysian Fields beyond the Chilterns robs death of its last remaining sting

E M C writes Your obituary notice of Dr Morland gives a vivid picture of his many sidedness I knew him for many years, but he still had a few surprises up his sleeve and of course lots for the unwary who thought him merely eccentric or affected We once had the great joy of a holiday shared with him his wife and family, and several young relatives. Led by him, the younger end of the party set off over the Gross Glockner pass to spend the night in the hut and go on to see the sunrise By then we were well acclimatised to the sun but I had had little experience of summer sun off the snow and by the evening my face was a mess with sunburn Next day after one look at it, Egbert said quietly, You and I are going to walk home by the valley, and leave the young ones to go over the top This was a great disappointment, but I couldn't question his judgment for I knew he was right. What I did not know was what a treat was in store, for his knowledge of Alpines was encyclopædic. I shall never forget that walk, taking it easy and stopping to look at first one and then the next little masterpiece, held out for me to see or just lifted up from the edge of the snow He felt a little guilty not to have warned me about the sun the day before, but, characteristically, it was the plants with which he was tender

Notes and News

HEALTH CENTRES AT YORK AND STRANRAER

WITHIN the past month two new health centres have been opened—at York and Stranraer

Performing the ceremony at York on April 14, Sir John Charles, chief medical officer of the Ministry of Health, declared that there was nothing so inspiring, so apt to promote smooth and efficient performance, as the outward and visible signs of bricks and mortar—such a sign as the new centre The centre is in the middle of a large post war housing estate and it will serve a population of about 25,000 In the first place, it will provide maternity and child welfare, health visiting, school nursing, and dental services, but the building has been designed in such a way that an extra wing of consulting rooms for general practitioners can readily be added later Alternatively, general practitioners may rent some of the existing accommodation, and discussions on this question are in hand The centre has been planned so that different kinds of patients are in independent units but they can all be easily supervised from the central administration offices The cost of the present building was £13,000

Stranraer's health centre is the second to be newly built in Scotland (the other is at Sighthill in Edinburgh [1]), and the first to be built adjoining or connected to an existing hospital It contains five consulting suites for the general practitioners of Stranraer, who have a total of 13,200 people on their N.H S lists In another wing there are three rooms and a dental workshop for local authority services, and the local authority will share another four rooms with the board of management responsible for the adjoining Garrick Hospital In addition the hospital has for its own use a changing room, a plaster room, and rooms for an X-ray unit The cost was about £33,000, of which the hospital authority will contribute some £12,000 The centre was opened on May 6 by Mr H R Smith, secretary of the Department of Health for Scotland

Hunterian Society

Mr A Dickson Wright has been elected president of this society for 1955–56

Royal Society of Tropical Medicine and Hygiene

The Chalmers medal for 1955 has been awarded to Dr W E Kershaw, lecturer in medical parasitology, Liverpool School of Tropical Medicine

N A P T Travelling Fellowship

The Scottish branch of the National Association for the Prevention of Tuberculosis offers a travelling fellowship (£250), for postgraduate study abroad, to a doctor working in Scotland on tuberculosis Applications should be sent not later than July 15 to the Scottish secretary, N A P T, 65, Castle Street, Edinburgh, 2

British Society for Research in Ageing

This society will hold a symposium on Thursday, June 9, at 2 P.M, at 41, Portland Place, London, W 1, on Endocrinology and Ageing Prof G R Cameron, F R S, will be in the chair The speakers will include V Korenchevsky (London), J A Loraine (Edinburgh), P L Krohn (Birmingham), and P J Thung, L Boot, and O Mühlbock (Amsterdam) Further information may be had from the hon secretary, Mr G H. Bourne D.SC, London Hospital Medical College, Turner Street, E 1

Sydney Body Medal

This medal has been awarded to Dr L Gordon Hopkins "for his unsurpassed services to medicine during fifty years in Southend."

Medical Records Exhibition

This exhibition will be held at the Bonnington Hotel, Southampton Row, London, W C 1, from 10 A.M to 6 P.M. on Saturday, May 21 At 11 A M Dr N M Goodman will give a lecture on Statistics and Records of Cancer The exhibition has been organised by the Association of Medical Records Officers to help hospital staffs to deal with problems of indexing, correspondence, outpatient waiting, admission and discharge procedure, and storage of records

International Society for Human and Animal Mycology

Last year, at the 8th International Congress of Botany, this society was founded to bring together those interested in the study of fungi living on humans and animals. The president is P Redaelli (Milan) and one of the vice-presidents is G T Ainsworth (Exeter) Further particulars may be had from Prof R Vanbreuseghem, Institute of Tropical Medicine, 155, rue Nationale, Antwerp, Belgium.

Hospital for Tuberculosis in Malaya

Dr M R J Snelling, chest physician at the King Edward VII Sanatorium, Midhurst, has been appointed the first medical superintendent to the Lady Templer Hospital for Tuberculosis at Kuala Lumpur This new hospital, which has 250 beds, is to be run on similar lines to those of the King Edward VII Sanatorium. A thoracic surgeon and a team are shortly to join Dr Snelling, and Australia is sending 28 nursing sisters

French Prize for Medical Film

At the fourth distribution by the *Presse Médicale* of prizes for medical films the prize for the best foreign entry was awarded to C E Engel (London) for his film on *Mitral valvulotomy for mitral stenosis* Honourable mention was given to the film by P Hansell (London) on *Grafting on the cornea* Applications for next year's competition will be received up to the end of next February, addressed to the *Presse Médicale* 120 Boulevard Saint Germain, Paris VI

Nursing Times

The golden jubilee of the *Nursing Times* was marked by a luncheon in London on May 6, under the chairmanship of Mr Daniel Macmillan Sir Harold Boldero recalled that only in the past half-century had nursing become fully established as a profession landmarks in this period included the foundation of the College of Nursing in 1916, the Registration Act of 1919, and the adoption by the college of the *Nursing Times* as its official journal in 1926 He went on to refer with regret to the fragmentation of medicine, and wondered whether the same sort of thing was happening in nursing Did those engaged in teaching nursing—who seemed to spend all their time on this task—go into the wards and see what was being done there? Did district nurses go into the hospitals? The medical curriculum was admittedly overloaded, and he asked whether the nursing curriculum was similarly overloaded or (which came to the same thing) there was insufficient time in which to teach everything included in the curriculum. Miss M. L Wenger, editor of the *Nursing Times*, spoke of some of that journal's activities Recently these had included the encouragement of recruitment to the mental hospitals and the offer of a bursary to enable a nurse to spend a year in the study of journalism, for they believed that nurses should be able to describe the results of their work. Dame Enid Russell Smith enunciated five aims for a professional journal First, it should advance professional knowledge (of course in language understandable to no layman) secondly, it should present professional political issues without bias, bitterness, or personalities, thirdly, it should put the work and aims of the profession in the setting of the fuller scheme of things (the margin between proper professional pride and arrogance was narrow), fourthly, it should set a high standard of professional ethics and support the best traditions (thus acting as the profession's memory); and fifthly, it should encourage the pioneering spirit, so that no reader, after studying any issue of the journal, could feel any self satisfaction at all The *Nursing Times* had succeeded in each of these aims Finally Miss S C Bovill spoke with pleasure of the association between the Royal College of Nursing, of which she is president, and the *Nursing Times*

A draft British standard for gas-cylinder trolleys has been issued by the British Standards Institution Comments should be sent to the institution 2, Park Street London W 1, before June 7

THE CLINICIAN AND
E PROBLEM OF MULTIPLE SCLEROSIS*

Douglas McAlpine
M.D Glasg F R C P
SICIAN IN CHARGE OF DEPARTMENT FOR NERVOUS DISEASES,
DLESEX HOSPITAL, LONDON PHYSICIAN MAIDA VALE
HOSPITAL FOR NERVOUS DISEASES

DURING the past quarter of a century there has been a able revival of interest in multiple or disseminated rosis particularly in America In the laboratory the perimental pathologist has evolved a technique by ich an encephalomyelitis can be produced in animals luding the monkey by means of subcutaneous or ramuscular injections of brain tissue along with an juvant consisting of heat killed tubercle bacilli. The ults of these experiments have suggested to some servers that brain tissue may contain a chemical agent ich acts as an antigen producing antibodies that react h constituents of white matter The part played by adjuvant used in these experiments is uncertain

Meanwhile, clinicians have contributed mainly in two ctions—first in geographical and racial studies and ondly in attempts to determine more accurately the ure of the disease.

Geographical surveys were undertaken first in Switzer d by Bing and Reese (1926) and subsequently in nmark (Gram 1934) Sweden (Sällström 1942), and ts of the United States of America (Kurland 1952) st of these surveys have suffered from one serious fect—namely that the results have been based either death certificates or on information obtained from neral practitioners. Notable exceptions have been those ently carried out by Allison and Millar (1954) in rthern Ireland and by Dr John Sutherland in Northern tland

Allison and Millar personally examined all cases ported to them by general practitioners over a three ar period After discarding 187 cases 700 remained in ich they were satisfied that the diagnosis was either obable or possible Using the census figures of 1951 ey were able to arrive at a prevalence rate of 7 9 per 000 after excluding persons under the age of 20 By termining the geographical distribution by place of set, Allison and Millar found that the disease in rthern Ireland does not affect rural populations more an urban nor did they find any evidence to suggest a cal incidence

Dr Sutherland has recently completed a survey of the ease in the Orkney and Shetland Isles the Western les, and the mainland counties of Caithness Sutherland ss and Cromarty Inverness, and Nairn I am grateful him for permission to refer to certain of his findings questionnaire was sent to all general practitioners in se regions asking for the names and addresses of all pected cases of multiple sclerosis ; replies were received m 93% of practitioners 180 cases were notified of hich 16 were rejected 10 other patients had either ed after the case had been notified or had removed from e region these 10 cases were discarded Of the maining cases 127 were classified as probable and as 'possible cases of multiple sclerosis On the sis of the 1951 census figures Dr Sutherland found an ter-all prevalence rate of 5 5 per 10 000 ; if possible ses were included the figure rose to 6 7 In the Shetland les the relative figures were 11 3 and 12 9 per 10 000 e highest rate yet recorded in Great Britain

In the Northern Ireland and Northern Scotland rveys a significant familial incidence was found to hich I shall refer later

The results of these surveys justify the hope that similar field studies of multiple sclerosis in Great Britain will be encouraged, particularly in areas with a reputedly high prevalence rate

Other contributions made by clinicians in recent years include studies of the course of the disease and its prognosis In the past estimates of its duration were usually based on fatal cases. A notable exception was Byrom Bramwell's (1917) follow up of a series of cases over a period of twenty years However, the main credit for introducing some order into this subject must go to Ragnar Muller (1949) whose conclusions are of particular value because of the size of his material and his application of the statistical method His results and those of other workers including Allison (1950) have shown that the outlook for the patient with multiple sclerosis is considerably better than was formerly supposed

These outstanding contributions must not blind us to the fact that other aspects of the natural history of the disease as well as its symptomatology have been largely neglected in recent years My primary purpose here is to indicate the further value of these two lines of study

Aspects of the Natural History

The Familial Incidence

Preoccupation with the hereditary forms of cerebellar and paraplegic disorder may be the main reason for the long delay in the recognition of a small but significant familial incidence in this disease It was the appearance of Curtius s paper in 1933 that stimulated interest in this subject. He found a familial incidence in 9 4% of 106 cases observed in Bonn and Heidelberg (Curtius 1933 Curtius and Speer 1937) Since no case of multiple sclerosis was detected in a control population he concluded that the incidence of secondary cases in the families of multiple sclerosis patients was considerably raised when compared with a control population Since 8 positive family histories were obtained in a series of 142 cases reported from the Middlesex Hospital in 1946 an additional series was investigated with Pratt and Compston (1951) In a total of 310 cases the familial incidence was 6·5% In the Northern Ireland survey the figure was 6 58% Millar and Allison were the first to compare the expected risk in siblings of patients with multiple sclerosis with the rate in a control population studied in the same area and at the same time They estimated the risk to be about ten times greater in siblings of patients than in the control population and agreed with our view that the excess risk is not due to a common environment or to infection but to a genetically determined predisposition In the Northern Scotland survey there were 12 families with more than one case of multiple sclerosis an incidence of 9·4% This figure errs on the conservative side since in 12 other families there was a positive history but as the diagnosis could not be satisfactorily established in the secondary cases they were excluded Dr Sutherland rejected a diagnosis of multiple sclerosis in three brothers living in the Island of Lewis affected by a progressive spastic paraplegia preferring to regard it as a purely hereditary condition In the Orkney and Shetland Isles the familial incidence exceeded 10% Parental consanguinity seemed a possible explanation for this high figure but the incidence proved to be comparatively low Dr Sutherland's observations which cover racial dietetic and other factors may throw further light on the relative parts played by heredity and environment in this disease

Precipitating and Aggravating Factors

At the end of the last century and the beginning of the present one there are many references in the literature especially German to the effect of such factors as infection injury physical exertion exposure to damp and cold emotional upset, and prolonged worry in unmasking the first symptoms of the disease In 1934 Hoesslin published a monograph devoted to these so called exogenous factors

---

*The Florence Tong lecture delivered before the Association of British Neurologists at Cambridge on March 25 1955

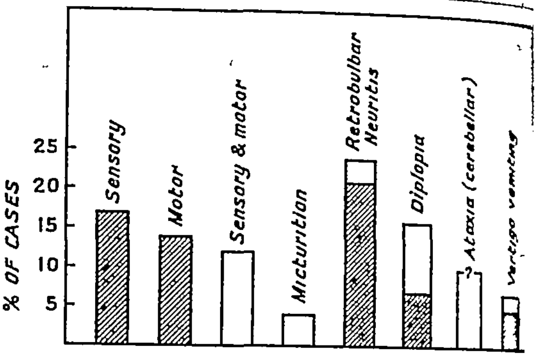
6878

The criteria necessary to establish a causal relationship between a supposed precipitating factor and the onset of the first symptom of multiple sclerosis or a relapse are (1) a temporal relationship, and (2) a significant incidence of the factor in comparison with a control series The time interval is difficult to fix, and a period of three months which we arbitrarily chose in studying these factors seemed reasonable (McAlpine and Compston 1952) However, if it could be shown that a causal relationship may exist between trauma, for example, and the onset of the disease, it would be necessary to visualise a longer time-interval than three months Turning to the second point, the evidence in the literature is of little value judged by present day statistical standards Bearing this fact in mind I propose to discuss briefly four conditions which appear with sufficient frequency in the immediate past history of these patients as to warrant attention

General health —It is by no means exceptional to find that for days or weeks before the appearance of the first symptoms, or accompanying them, the patient has not felt in his or her usual health, has lacked energy, has tired easily, and in addition may have noticed headache and vague pains in the back or limbs On inquiry these somewhat indefinite symptoms may have coincided with a period of overwork or overstrain, but in other patients no adequate cause can be found Although by no means the rule, these premonitory symptoms deserve further study, since if we understood their meaning they might provide a partial clue to the ætiology of the disease

Infection —This usually takes the form of a cold, a sore throat, or influenza Bramwell obtained the high figure of 14% of infections preceding the onset in 200 cases, and Hoesslin 10 5% in 109 acute cases, which is approximately the figure obtained by Compston and myself in 250 consecutive cases Taking these figures and those in other series into account, it may be said that 10% represents the approximate incidence of some form of infection before the onset If attention be paid to this question it will be found that not infrequently in an established case of the disease, a relapse may immediately follow an upper respiratory infection

Trauma —The third factor is trauma, whose occasional relationship to the onset of multiple sclerosis has been commented upon by numerous writers (McAlpine and Compston 1952) In our own series of 250 consecutive cases particular care was taken to exclude trauma from a fall due to the disease In the three months preceding the onset there was a history of trauma, including dental extractions but not surgical operations, in 36 patients (14%) as compared with a similar history in 13 patients (5 2%) in a control series of hospital inpatients With regard to the site and degree of trauma, it has been assumed by most writers that the injury must be cranial or spinal and severe in degree (Keschner 1950) Whether the changes set up in the nervous system are primarily vascular or chemical, there seems no reason to exclude the limbs when considering the site of trauma Hoesslin was the first to suggest that there may be a relationship between the site of the trauma and that of the first symptom Of our series of 250 cases, in 22 out of 36 (61%) patients who gave a history of trauma, there appeared to be a correlation between the site of the injury and the part of the body, usually a limb, in which the first symptom appeared We also showed that the relapse rate within the three months following trauma, whether this was accidental or surgical, was significantly greater than the expected relapse-rate during the same period This evidence, of which fuller details are given in our paper, suggests that slight or severe trauma, including an operative procedure, to a limb or any part of the body, may occasionally precipitate the disease or may be t cause of a relapse



Initial symptoms of multiple sclerosis, occuring alone (hatd columns) or in combination, in 309 cases.

Allergic disorders —The incidence of allergic disord in the past history of patients will naturally dep on the scope of the inquiry In our series we fou no significant difference in the remote past history multiple sclerosis patients as compared with a cont group , but in the three months preceding the onset the disease, and in the subsequent months or years, a a history was obtained in approximately 9%, as com pared with an average of 2 8% in a control series.

If mental stress be added to the factors which I ha mentioned—namely, a lowered state of general heal trauma, infection, and an accompanying allergic disord —it may be estimated that one at least of these occu in a close time relationship to the onset in roughly eve other patient, an estimate which probably errs on th conservative side

Features of the Early Symptomatology

There is still no consensus of opinion as to the relati incidence of the initial symptoms It therefore seems worth analysing the notes of the 309 cases finally dia nosed as multiple sclerosis after admission to the Depar ment for Nervous Diseases, the Middlesex Hospital, und myself and my colleague Dr Michael Kremer, over five year period from January, 1950, to December, 195 Doubtful cases were excluded By limiting the analys to inpatients admitted to the same department it wa hoped that some degree of uniformity in history takin methods of investigation, and final diagnosis would b achieved

In constructing the accompanying figure, motor a sensory symptoms associated with brain stem signs ha been omitted , so the columns marked " motor " a " sensory " refer to cases in which there was a hi probability of one or more plaques in the spinal co Symptoms rarely met with at the onset, such as a isolated facial palsy, have also been excluded

This analysis emphasises the frequency of a mono symptomatic type of onset, which was seen in near two thirds of the cases in this series An isolated retr bulbar neuritis may be expected as the first sign in ab one patient in every five , paræsthesiæ in one out o every six , and thereafter, in diminishing order o frequency, motor weakness (usually in a lower lim double vision, vertigo, and vomiting

One of the characteristic and at the same time puzzl features of multiple sclerosis is the extreme variabil in the mode of onset and duration of the first symptom At one end of the scale is the so-called apoplectifor onset recognised by Charcot , at the other end is the sl insidious appearance of a paraplegia due to spinal plaques How to explain these two modes of onset on the bas of a common pathological process is one of the ma unanswered questions relating to this disease Tr oints, however, should be borne in mind: first the age ncidence differs, an abrupt onset being more common in ounger patients while the slowly progressive form of he disease mainly occurs in those over the age of 40, nd, secondly as in certain other diseases—notably heumatoid arthritis—the individual's reaction to the orbid process can apparently determine the tempo of he initial symptoms and the subsequent course

ransitory Episodes and Exacerbations

The adjectives "transitory" fleeting or short-ved" are often used by writers in describing early ymptoms. The vagueness of these terms leaves the verage reader in some doubt as to their meaning hough he may gain an impression that they indicate a eriod of one or more days. Accordingly serious attention s seldom given to attacks of blurred vision double vision iddiness, or pins and needles in a limb lasting a few ours or even minutes. Yet such episodes are not ncommon in the past history of patients presenting ith undoubted signs of the disease

The factors determining the onset of these fleeting arly symptoms deserve further study So far as my own mited observations go, it seems that, in the main they re similar to those that may provoke more lasting ymptoms I have been struck by the fact that a patient resenting with well marked sensory disturbance in a and, may for several weeks previously have noticed emporary tingling and perhaps numbness in the fingers f the same hand on awaking from sleep or sometimes fter using the hand Likewise an attack of retrobulbar euritis may be preceded by episodes of blurred vision rought on by exertion or emotion The following case s illustrative

Mrs. A aged 23 a hairdresser when playing tennis one ay in September 1953 noticed hazy vision with difficulty in eeing the ball She stopped playing and after a short rest er vision became normal. Subsequently whenever she layed tennis or danced vision was temporarily blurred. In lay 1954, she began cycling to work a distance of about a ile By the time she arrived vision was so poor that she was nable to start work until she had rested for a short time oon afterwards she also noticed numbness in the right hand or some hours after cutting several customers hair in ccession.

In June 1954, vision was 6/5 both eyes, the fundi were ormal and no scotoma could be demonstrated (Mr A J B oldsmith) By July she found that even mild exertion, such s walking quickly affected her eyes to an increasing extent nd soon vision became permanently blurred By October ision was 6/60 in both eyes both discs were pale and a small ilateral central scotoma was now present

On admission in December vision had not improved and he now showed nystagmus and bilateral extensor plantar esponses. After cycling on a fixed bicycle vision became worse comparison of the scotoma in the right eye on an Amsler's hart before this exercise and after four minutes showed that t had markedly extended Five minutes later the central efect had returned to its previous size

To be distinguished, at least clinically from these ransitory initial episodes are the temporary exacerba tions of symptoms which may be a sequel to an estab lished plaque. Of 250 cases investigated by Compston nd myself 82 (32%) gave a history of temporary worsening of symptoms during stress, a finding confirmed y Pratt (1951) An emotional upset may act rapidly n motor function, paræsthesiæ and vision Likewise xertion may have the same effect. These temporary hanges are of course seen in other organic conditions of he nervous system such as traumatic paraplegia but t is our impression that they occur more easily and are nduced by a larger range of exciting factors in multiple sclerosis than in other organic conditions

Franklin and Brickner (1947) suggested that these hanges are due to vasospasm for they observed local ised constriction of retinal arteries during episodes of blurred vision An increased vulnerability of the axis cylinder to chemical influences offers an alternative explanation

Symptom and Lesion

At first glance any attempt to correlate disturbance of function and of structure in multiple sclerosis may seem profitless However not infrequently the earliest symp toms are caused by a focal disturbance, thus permitting a clinical study of their mode of evolution I have in mind particularly sensory symptoms due to invasion of the spinal cord As Oppenheim (1911) originally pointed out tingling and numbness are usually caused by one or more plaques in the posterior columns Furthermore since the cervical cord is often attacked early in the disease a special opportunity is afforded the clinician of studying sensory symptoms, since at that level afferent impulses from all four limbs and the trunk are represented in a known anatomical relationship to each other within a small area (McAlpine 1954)

Although tingling and numbness may be confined to a small area on a limb or the trunk not uncommonly they tend to spread by noting the original site of the paræsthesiæ and direction of spread it becomes evident that this is often determined by the anatomical arrange ment of the proprioceptive fibres within the posterior columns. For example a spread of numbness from a hand to the shoulder and then down the homolateral trunk and finally to the lower limb is indicative of a focus in the column of Burdach extending inwards to the column of Goll. Similarly a spread may take place in the reverse direction Thus the mode of spread appears to be determined by contiguity of structure

Another feature which can be recognised clinically is the symmetry sometimes shown by plaques. For example, it is not uncommon for paræsthesiæ to affect simultane ously or in quick succession corresponding parts of the lower or upper limbs, and be followed by a similar mode of spread in the four limbs A further example of sym metry is provided by retrobulbar neuritis which, contrary to many statements may affect both eyes simultaneously in multiple sclerosis. This symmetrical tendency of plaques, which many years ago was commented on by pathologists poses yet another question for which at present there is no satisfactory answer

Multiple Sclerosis or Spondylosis

So far I have considered certain features of the relapsing and remitting form of the disease Presenting a striking contrast in its mode of onset and its course is the so-called progressive paraplegic or spinal form of multiple sclerosis which chiefly affects the middle-aged

In the analysis of the 309 cases already referred to I came across 27 with signs of a spastic paraplegia in which the diagnosis of multiple sclerosis was at first in doubt During the same period 31 cases of spinal cord compres sion due to tumour (excluding secondary deposits) came under the care of Miss Diana Beck Dr M Kremer or myself. In recent years myelography has substantially reduced the number of cases of cord compression mistaken for the spinal form of multiple sclerosis Today the neurologist, while constantly aware of this pitfall, must also take into account the possibility of cervical spondy losis when confronted with a paraplegia in middle age Over the five year period already referred to there were 30 such cases. An analysis of this group and that of the 27 patients with the spinal form of multiple sclerosis showed that, while the clinical picture in the two groups was broadly similar there were certain points of differ ence First the average age of onset differed in the multiple sclerosis group it was 42 and in the cervical spondylosis group 51, the youngest patient being 27 and the oldest 68 It is in the fifth decade of life however that the distinction between these two causes of para plegia may be difficult A gradual onset and slow progression of motor weakness—first in one lower limb and then in the homolateral upper limb—without any sensory symptoms or signs, may occasionally occur in the progressive form of multiple sclerosis, none of our cases of myelopathy associated with cervical spondylosis showed this pseudohemiplegic type of progression. In multiple sclerosis short attacks of tingling and numbness, usually brought on by exertion, may antedate motor weakness by weeks or months, but such a history is rarely obtained in cervical spondylosis. The spread of paræsthesiæ, when it occurs in multiple sclerosis, tends to be much more rapid than in spondylosis. Pain in the upper or lower limbs is a well recognised feature of the early phase of spondylosis, yet it was not a rare symptom in this small group of multiple sclerosis patients, being among the presenting symptoms in 8 of the 27 cases; it was usually referred to one or both lower limbs or the back. Scattered references to pain in this disease can be found in the literature, and since its interpretation remains in doubt it is worthy of further study.

A history of early disturbance of sphincter control was found more commonly in multiple sclerosis as compared with the myelopathy of spondylosis, the figures being 14 of the 27 multiple sclerosis cases compared with 8 of the 30 spondylosis patients. An episode of temporary incontinence early in the history should suggest multiple sclerosis.

The course of the spinal form of multiple sclerosis is sometimes interrupted by a superimposed relapse; this occurred in 3 cases in this series in the form of paræsthesiæ which developed over the course of a few days and then receded. I have not met with similar episodes in the myelopathy of spondylosis.

Regarding signs, the upper limb reflexes afford little help in differentiating between these two groups of patients—particularly depression or absence of one or more of these reflexes, since this occurred with almost equal frequency in the two groups. While muscular wasting in the upper limb was relatively more common in the spondylosis group, 2 cases of tetraplegia due to multiple sclerosis showed wasting of the intrinsic muscles of the hands, a finding which was commented upon by Déjerine (1884) when he drew attention to the similarity between this form of the disease and amyotrophic lateral sclerosis.

The presence of nystagmus proved to be the most helpful single diagnostic sign; it was present in 14 of the multiple sclerosis cases, but in only 4 of those with spondylosis. In these 4 patients it was purely horizontal in type and was associated with evidence of involvement of the upper cervical cord as judged by exaggeration of some of the upper limb reflexes or by radiological evidence of spondylosis as high as C3–4. In the multiple sclerosis group a well marked rotatory or monocular nystagmus was not unusual and provided evidence of an extraspinal lesion.

Apart from nystagmus, evidence of one or more lesions above the level of the spinal cord was found in 9 of the multiple sclerosis cases; unilateral temporal pallor of the discs (4 cases), mild dysarthria (3 cases), and an exaggerated jaw-jerk (2 cases). Euphoria was noted in 2 patients but only in the course of a follow-up when symptoms had been present for several years.

The findings in the cerebrospinal fluid proved of the utmost value, particularly in those cases in which signs were confined to the spinal cord. 12 of the 27 multiple-sclerosis patients showed a marked paretic curve; in 6 others there was a mid-zone curve of at least 2's. In 1 case the only abnormality was a rise in the protein figure; in the remaining 8 cases the fluid was normal on one or more occasions. By contrast, a mid-zone curve of 2's was only found in 2 cases of cervical spondylosis; in the remaining 28 cases the Lange curve was normal.

Before leaving these two groups of patients, I wish briefly to refer to 8 cases in the multiple sclerosis group which showed clear evidence of cervical spondylosis. The youngest patient was 31 at the onset of symptoms and the oldest 51, with an average age of 42. The diagnosis of multiple sclerosis in these patients with cervical spondylosis was based on the points already mentioned, with the addition of myelography in two cases. In 2 cases protein figures of 130 and 120 mg. per 100 ml. were found.

A woman, aged 44, had for two years received treatment for pain in the neck and left arm due to well marked cervical spondylosis. Rather abruptly she began to stagger when walking and she was admitted under the care of my colleague, Dr. Kremer. Among the positive signs were a pronounced monocular nystagmus, limb ataxia, a mild paraparesis, and a strongly paretic gold curve. She responded only slightly to traction and some months later was readmitted with an abrupt progression of symptoms.

The second case was a male, with onset of symptoms at the age of 31, who five years later was dysarthric and showed temporal pallor of one disc and nystagmus. There was no evidence of block on flexion and extension of the head during lumbar puncture.

It is probable that in these two patients the spondylosis accounted in some degree for the high protein figure. A marked rise in protein occurs rarely in uncomplicated cases of multiple sclerosis. For example, only 5 out of 512 spinal fluids from cases of multiple sclerosis examined by the Courtauld Institute at the Middlesex Hospital showed a figure of 100 mg., or more, per 100 ml.

Conclusions

Certain of the facts mentioned in this lecture may be summarised as follows.

First, of the chronic organic nervous diseases occurring in the British Isles, multiple sclerosis now appears to be the commonest. The surveys of Northern Ireland and Northern Scotland show that in these parts of our islands at least one adult in every 13— is affected by it. The figure for England and Wales is probably only a little behind this one.

Secondly, there is a small but significant familial incidence varying in Great Britain from 5% to just over 10%. Since it is exceptional to find more than two members of a family, whatever its size, affected by the disease, it must be assumed that when present the genetic influence is usually weak and must be reinforced by constitutional or environmental factors before the nervous system is attacked, and furthermore, that the disease may develop in the absence of any obvious genetic influence.

Thirdly, in some patients a variety of factors, including ill health, an infection, trauma, and emotional stress may precipitate not only the onset of the disease, but also relapses.

The fourth fact about the disease concerns its abrupt onset and the natural tendency for symptoms to remit and later recur—features which for many years have been recognised as likely to provide a clue as to its ætiology.

Lastly, the considerable variation in the behaviour of the disease in its earlier stages must depend on the individual's reaction to it.

The Allergic Theory

For too long our attention has been fixed on the nervous system in multiple sclerosis. Detailed though the average history may be regarding events relating to this system, account is seldom taken of the recent and past general medical history. Yet it is in the medical background of these patients that we must look for the events which in a small proportion of the population initiate changes in the myelin sheath. Of recent views as to the cause of the disease, the so called allergic theory is perhaps the one most acceptable to the clinician. The occasional familial incidence; the nature and variety of the precipitating factors; the presence of some other form of allergy, before or after the onset, in a significant proportion of cases; an abnormal sensitivity to drugs d lastly the abrupt onset and characteristic relapsing d remitting course—all these factors may be cited in pport of the view that multiple sclerosis represents a pe of immunity reaction in the central nervous system cAlpine and Compston 1952)

Since confirmation or otherwise of this hypothesis ay be long delayed perhaps it is permissible to consider e nature of the hypothetical sensitising agent or agents. general allergens are derived from bacteria from otein derivatives and from drugs Since the breakdown oducts of bacteria constitute their commonest source, appears likely that, if sensitisation plays any part in he genesis of multiple sclerosis, an infection initiates he process, at least in some patients However, in ractice it would be difficult to prove such a relationship —first because of the time lag that might theoretically ccur between the infection and the first clinical evidence f the disease (McAlpine 1946) and secondly because s Rich (1947) has pointed out in discussing the question f allergy once a tissue has become sensitised it may bsequently react to a wide range of substances Support for the idea of a latent or asymptomatic phase of ultiple sclerosis comes from a consideration of the part layed by the so called precipitating factors. These are learly not strictly causal but in the words of Lumsden, 'either they fire off or trigger' an intrinsic self propagating mechanism, or they provoke the onset of symptoms n connection with areas of the white matter already nvolved by the disease process' (McAlpine Compston and Lumsden 1955) The second of these postulates eems probable and is consistent with the theory of llergy

Course of the Disease

This leads me to consider briefly certain features of arly symptomatology and the light they may throw on he nature of the initial change in myelin sheath Transitory and recurrent symptoms such as diplopia, blurred vision and paræsthesiæ, which in some patients may onstitute the earliest evidence of the disease, could be xplained on the basis of the so-called shadow plaque eferred to by Lumsden (1951) In this stage of partial demyelination it is not difficult to imagine that the nderlying axis cylinder might react abnormally to a variety of stimuli If the concept of an initial asymptomatic phase of the disease be accepted, does demyelination begin during this period or is there a stage of pre demyelination in which the complex cytochemical balance of the sheath is in some way altered?

In 1903 Williamson, of Manchester was struck by the similarity between the pattern produced by the application of a soluble dye to the cut surface of the spinal cord and the mode of development of plaques In 1933 Hallervorden and Spatz drew attention to the occasional occurrence of a ring formation in the early plaques of multiple sclerosis similar to that observed in Balo's concentric sclerosis. They attributed this type of formation to diffusion outwards from a central focus as in the so-called *Liesegang* phenomenon a subject recently discussed by Lumsden (McAlpine Compston and Lumsden 1955) The tendency for early symptoms particularly paræsthesiæ to spread according to contiguity of structure lends support to the possible rôle of a process of diffusion

The next question concerns the important issue as to whether arrest of the disease is ever possible For the pathologist this seems unlikely since plaques tend to evolve slowly and progressively On the other hand the clinician is aware of cases in which after one or more episodes no fresh evidence of the disease is apparent for many years and even in some instances for the rest of the patient's life Unless there is a system for following up early cases most of these patients will be missed for they may have no occasion to report either to their general practitioner or to hospital From my own observations I am satisfied that the incidence of these mild cases with a good resistance to the disease is rather higher than is generally supposed

It may be possible to reconcile these differing view points of clinician and pathologist The manner in which early symptoms clear up and may remain in abeyance for several years emphasises the potential reversibility or at least non progression of the early lesion; by contrast we are well aware of the probable course when paraplegic or cerebellar signs become established It is in this type of case that we can understand the evolution of the plaque as seen in the post mortem room

Treatment

Lastly brief reference must be made to the present unsatisfactory attitude towards treatment This attitude is determined by two beliefs—first that a serious degree of disability is inevitable in all cases however treated and secondly that treatment consists solely in palliative measures I have already pointed out that the *prognosis* as a whole is less unfavourable than was formerly thought and in some patients the disease runs a relatively benign course As regards treatment, the lack of an effective remedy should not blind us to the necessity of adopting a more positive attitude towards these patients, particularly in the early stage of the disease before irreversible changes in the nervous system have taken place Assuming that constitutional factors are important in the ætiology of multiple sclerosis, then it is our duty first to ensure an adequate period of rest in bed after the onset or a relapse followed by a long period of convalescence and secondly, to increase as far as possible the patient's resistance to the disease by close attention to physical and mental health over the first few crucial years

Owing to its capricious behaviour the *assessment of* treatment in multiple sclerosis has always presented difficulties. Yet the necessity of devising a *method of* evaluating a particular remedy is obvious Compston (1953) has suggested a formula by which the relapse rate before and after treatment can be compared. This method however does not cover the effect on recent symptoms

After consultation with Dr Richard Doll a form of trial has been devised in which a control group of patients can be used Briefly the trial is divided into two parts. The first enables a comparison to be made of the effects of treatment during a month's *stay in hospital* in two groups of patients one on the drug *under trial* and the other on some form of recognised treatment such as arsenic The object of the second trial is to assess the effect of the drug on the *relapse rate* It is hoped that experience gained during the next year will show the value of these two forms of trial

I would like to conclude with two observations The natural history *of multiple* sclerosis suggests that it is not due to a single cause but to the interplay of a number of factors—*genetic constitutional* and environmental Despite its complexity we *as neurologists* should not be content to leave this problem to the laboratory worker but with widened outlook should endeavour to play a part in its solution

REPORTS from the United States and elsewhere indicate that hydrocortisone (17-hydroxycorticosterone, or compound F) ointment is highly effective in the treatment of various pruritic dermatoses

Sulzberger (1954) found it helpful in infantile eczema, atopic (prurigmous) dermatitis, contact eczematous dermatitis, otitis externa, nummular eczema, seborrhœic eczema, pruritus ani et vulvæ, exfoliative erythroderma of eczematoid or seborrhœic type, and some cases of eczematous and lichenified eruptions of the hands, feet, eyelids, face, neck, and genitalia, also in the "distinctive exudative, discoid, and lichenified dermatosis" of Sulzberger and Garbe Hydrocortisone has proved ineffective in pemphigus vulgaris, lichen planus, alopecia areata, psoriasis, and discoid lupus erythematosus, it does not inhibit the development of erythema from exposure to ultraviolet rays (Everall and Fisher 1952)

Alexander and Manheim (1953) and Malkinson and Wells (1954) have formed similar opinions, but they consider that hydrocortisone is ineffective in general exfoliative dermatitis, autosensitisation, and "-ide" (bacterial or fungous allergy) eruptions

McCorriston (1954), using hydrocortisone ointment in various vehicles, obtained 75–100% relief in 104 children and infants with eczema

Robinson (1953) obtained dramatic relief in 20 of 28 patients with atopic dermatitis, in 5 of 8 patients with pruritus vulvæ, and in 1 of 3 patients with pruritus ani 1 patient with discoid lupus erythematosus showed a good response and 2 showed fair responses

Sidi et al. (1953) state that the most striking effect is on pruritus, the action being immediate and lasting for at least twelve hours They used it for exogenous, allergic, seborrhœic, nummular, and purpuric eczemas, for pruritus, for chronic dermatitis of the eyelids, and for various other dermatoses

Goldman and Preston (1954) treated 22 cases of poison ivy dermatitis, with excellent results in 3, slight changes in 5, and no change in 14 cases

These reports suggest that hydrocortisone ointment relieves itching and reduces the manifestations of inflammation in a number of skin diseases, but in none of the above trials were concealed controls employed In the trial of any new treatment for pruritic conditions it is important to eliminate as far as possible the influence of suggestion, particularly when physical signs are slight and reliance has to be placed on subjective impressions

When anti histamine drugs were introduced, it was soon reported that they were effective local applications for the relief of itching Many of these claims were based on uncontrolled trials, on comparisons with previous remedies, or on trials which employed contralateral controls Later, Baldridge (1951) treated 41 patients with 5% phenindamine ('Thephorin') ointment on one side and its unmedicated base as a control on the other These were presented as "slightly different forms of the same medication" to the patients who were asked to estimate the percentage of relief on the two sides 47% of the areas treated with thephorin were reported as relieved, and 49% of the areas treated with the unmedicated base were reported as relieved Many dermatologists now agree that most anti histamine drugs are useless when applied topically

It can be said of contralateral controlled trials that at least four fallacies may invalidate the results

(1) Absorption may lead to remote as well as local effects

(2) The trial substance may inadvertently be transferred to the opposite side

(3) Unless the lesions on the two sides are of equal intensity and duration, they are not strictly comparable (e g, the response to treatment of an eczematide cannot be compared with that of the primary lesion—perhaps an area of unilateral hypostatic eczema—from which it developed) This difficulty can be overcome by random allocation of treatment and control to right and left sides, but even then, unless a large number of patients are included in the trial, the results may prove inconclusive

(4) There may be a *Mitreaktion* (Siemens 1951, 1953) in which, when a patch of skin disease is treated on one side of the body, untreated areas on the opposite side also show improvement This may be the result of a spinal reflex, or it may be accounted for by the reduction in the amount of circulating histamine which follows treatment

The Present Trial

In assessing the value of hydrocortisone ointment ('Hydro Cortisyl,' Roussel), we used concealed, alternating, self contained controls, the patients themselves recorded their daily progress over fourteen consecutive days on cards supplied to them each week

CONTROL BY ALTERNATION

A trial in which (*a*) the vehicle alone and (*b*) the substance being tested are used alternately in treatment has much to commend it, provided certain criteria are observed, and certain uncontrollable factors are appreciated

1 The number of patients tested in each group must be sufficiently large

2 The patient should be unaware that an ointment containing a trial substance is being tested against the ointment alone

3 The clinician should not know when the patient receives the trial ointment and when he receives the vehicle also until the specified period of the trial has been completed and all data have been recorded

4 It is possible that either substance will continue to exert some effect during the first few days after replacement by the other Thus the test remedy (or the vehicle alone) when applied during the second week may appear more (or less) effective than in the first week

5 The days of starting treatment should be evenly distributed through the week so as to spread the possible influence of weekends and bank holidays

6 The influence of menstruation is unlikely to be important if patients are introduced to the trial as they attend for treatment, without reference to the stage in the monthly cycle

7 If the whole trial covers several months, and preferably a year or more, and if patients enter it at various times, the influence of seasonal climatic changes is unlikely to important

8 The influence of extraneous factors such as fatigue, emotional disturbances, &c, may affect individual results Such factors should be noted at each attendance

9 Any record keeping by the patient is an abnormal state of affairs In suggestible patients results may prove better than might be expected, in very conscientious patients an increased awareness of attention to the skin may cause increased awareness of itching Both possibilities are likely, not only with the

hicle but with the test substance as well Reciprocal short m trials are a useful means of determining the worth of a w remedy for chronic benign cutaneous reactions : the tient runs no risk and suffers no inconvenience if the hicle is harmless the vehicle may in fact prove helpful itself

THE RECORD CARDS

'Record of itching' cards adapted from cards used r Hodgkinson (1954) for controlled clinical trials of algesic drugs, were designed for the trial as follows

RECORD OF ITCHING

ate

atient s Name Record No

	Very good day (no itching)	Fair day (less itching)	Average day (usual itching)	Bad day (more itching)
un.				
lon				
'ue				
Ved.				
hu				
ri.				
at.				

Place X in appropriate space each morning for previous day

The patient s name and record number and the date were ntered by the clinician and a mark was made to show on hich day of the week the trial began. The patient s attention was then drawn to the request at the foot of the card Place X in appropriate space each morning for previous day " The ppropriate spaces recorded whether the patient had had a "very good day (no itching) a fair day (less itching) an "average day (usual itching) or a 'bad day (more itching)

The patients were unaware that two different preparations were being given to them They were informed that it was desired to find the worth of a remedy and that for this purpose a trial lasting two weeks was necessary No salesmanship ' was employed and the use of superlatives or of such adjectives as American ' and special' was avoided On the contrary, a restrained remark such as the following was made Please apply the ointment very thinly twice a day and record its effects on this card At the second attendance no matter what the result of the first week s treatment had been a comment was made such as the following A fortnight s treatment is needed to give the remedy a thorough trial It is best to have a fresh supply Please discard any ointment that remains and indicate results on this card for another week All patients coöperated well and seemed to understand what was required of them There were no 'spoiled papers.'

The method of prescribing was to write on the standard outpatient prescription card : HC ung trial 1st (or 2nd) week 5 g store no 1 The patients were told that only a small quantity of ointment could be provided for one week s treatment and they were sent to a special section of the outpatient dispensary This enabled concealed records to be made and kept by one pharmacist who was also responsible for arranging an approximately equal distribution between the A B (hydrocortisone→vehicle) and the B A (vehicle→hydrocortisone) trials He did this by alternating the A B and the B A sequence This resulted in a random distribution because there were eight different skin conditions included in the trial There were 66 patients in the A B sequence and 63 in the B A while 3 patients did not complete the trial We four clinicians had no means of telling which patients received the A B and which the B A sequence because we did not know when one of us had introduced a new patient to the trial—or for that matter the order in which the patients arrived at the dispensary 5 g of ointment or base was dispensed as a rule but sometimes 10 g was given The control ointment (of propylene glycol polyethylene glycols, and zinc stearate) was the same as the vehicle for the 2 5% hydrocortisone acetate ointment ; the two ointments were identical in appearance Identical plastic ointment boxes were used for the trial substance and for the base They were not labelled in any way to indicate the nature of the contents At the end of each fortnight s trial the pharmacist was asked to divulge the treatment that had been given each week, so that a decision might be made on the future treatment of that patient Progress notes were also made at each attendance, the patient s verbal descriptions being recorded , these made a valuable parallel study to the record cards. Changes in physical signs were also recorded.

In some of the conditions—e.g anogenital pruritus—physical signs were often slight or absent the changes being mainly or entirely subjective In patients with multiple lesions—e.g some cases of discoid eczema—the trial ointments had to be applied to one area only, while the remaining lesions were treated with some other bland local application As far as possible sedatives were withheld during the trial period if they were necessary, they were given for both weeks in identical doses

On inspecting both cards and after allowing for carry over effects it was usually easy to decide which preparation was the more effective The subjective results recorded during the last day or two of a week s trial were often poorer than during the middle of the week. We believe that this was often due to the necessity for very sparing use of the ointment towards the end of each week because of the small amount (5 g) that was usually supplied

In cases where the 2 5% hydrocortisone ointment proved more effective than the base alone treatment was continued with 1% hydrocortisone ointment Sometimes treatment was continued with the base and a change-over to 2 5% or 1% hydrocortisone ointment was made after a further week or two without the patient s knowledge It was thus possible to clarify inconclusive impressions gained from the first trial. It was also possible to compare the efficacy of 2 5% with 1% hydrocortisone ointment ; sometimes the 2 5% preparation was necessary for complete control in others 1% was sufficient

MATERIAL

Included in the trial were 132 patients (72 males and 60 females), with the following conditions

25 with anogenital pruritus
21 with lichen simplex.
12 with infantile eczema.
22 with Besnier's prurigo
23 with discoid eczema
11 with chronic idiopathic eczematous dermatitis of the hands
11 with otitis externa
7 with pruritic psoriasis mostly anogenital

RESULTS

Points were allotted daily to each patient studied allowing 2 points for complete relief, 1 for partial relief 0 for no change, and –1 for worsening These numerals indicate trends only and in no way imply degrees or percentages of relief The points scored are recorded on block diagrams in figs 1–8 These show great individual variations of subjective relief We have thought it valid to summarise the effects obtained in 'hydrocortisone" and vehicle' groups during the week of their application The daily means are set out in table I.

The number of patients in a few of the groups was too small for dogmatic statements but it is clear from this table that appreciably greater improvement sometimes resulted from the use of hydrocortisone No absolute criterion of efficacy can be applied but on the above rating the results may be summarised thus :

Lichen simplex discoid eczema and otitis externa.—The results were strongly in favour of hydrocortisone

Infantile eczema and idiopathic eczematous dermatitis of the hands.—The results though apparently in favour of hydrocortisone, were less conclusive

Pruritic anogenital psoriasis—The results were equivocal In the course of treatment with hydrocortisone ointment 6 patients improved and 1 worsened, while with the vehicle alone 5 patients improved and 2 worsened This suggests that the vehicle was responsible for the improvement

Besnier's prurigo—Slightly better results were obtained with the vehicle alone, but neither hydrocortisone nor the vehicle produced very good results Undoubtedly the trial was often inadequate in this condition, because the cost and scarcity of hydrocortisone made it advisable to use it only on the worst, lichenified areas in these patients Nevertheless, clinical and electro encephalographic evidence (Ingram 1955, Russell and Last 1955) indicates that this disease affects the whole ectoderm (nervous system and skin), so it is not surprising that local treatment by itself should prove ineffective

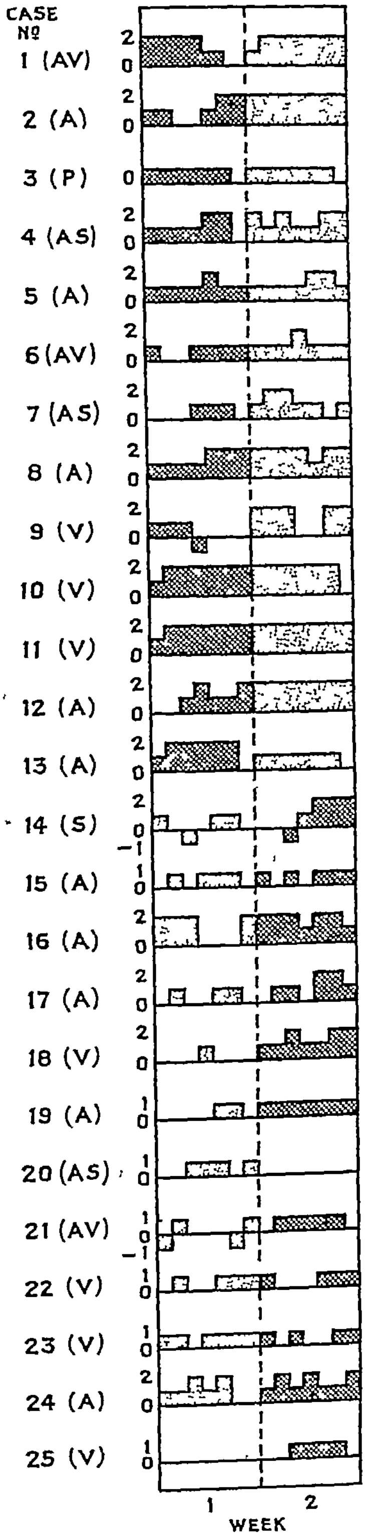

Fig 1—Results in 25 cases of anogenital pruritus.
A = anal P = perineal
S = scrotal V = vulvar

Anogenital pruritus—Slightly better results were obtained with the vehicle alone Nevertheless excellent longer term results were obtained in this condition with hydrocortisone (see below), 32% of patients being completely relieved and another 24% much improved We can only suggest that our equivocal findings in the "switch over" trial were due to one or more of the following factors the shortness of the trial, the undoubted efficacy of the vehicle itself, the carry over effects from one week to the next, and, in some cases, the influence of suggestion There was no obvious difference between the results obtained in anal pruritus and in genital pruritus Patients with distinct physical signs—chiefly lichenification—responded best, and those without physical signs responded worst This is not surprising, for pruritus without physical signs is probably of central origin

SIDE-EFFECTS FROM HYDROCORTISONE OINTMENT

Remote Effects

We have seen no evidence of remote ill effects following the use of hydrocortisone ointment

Smith (1953) found no significant change in the eosinophil count after the inunction of 6 g of 2 5% hydrocortisone-acetate ointment, and he thought it unlikely that amounts of hydrocortisone so small as to escape detection could account for the therapeutic effects reported No systemic ill effect has been reported from the prolonged application of hydrocortisone ointment.

Local Irritation, Sensitisation, and Aggravation of Infective Dermatoses

In the series of Malkinson and Wells (1954) irritation developed in 4 of 71 patients treated, and the treatment was stopped, but no case of sensitisation to hydrocortisone has yet been reported There were no cases in our series 3 of Robinson's (1953) patients complained of increased burning and itching when the ointment was applied, and 2 of them were found to be sensitive to the lanolin in the ointment base The ointment used in the present trial did not contain lanolin A few of our patients stated that it was "too drying," but the great majority found it comforting and aesthetically acceptable The occasional complaint of undue dryness can be overcome by having an alternative vehicle of hydrous ointment type, but the routine use of a greasy vehicle of this sort would be liable to cause maceration of the skin at some sites

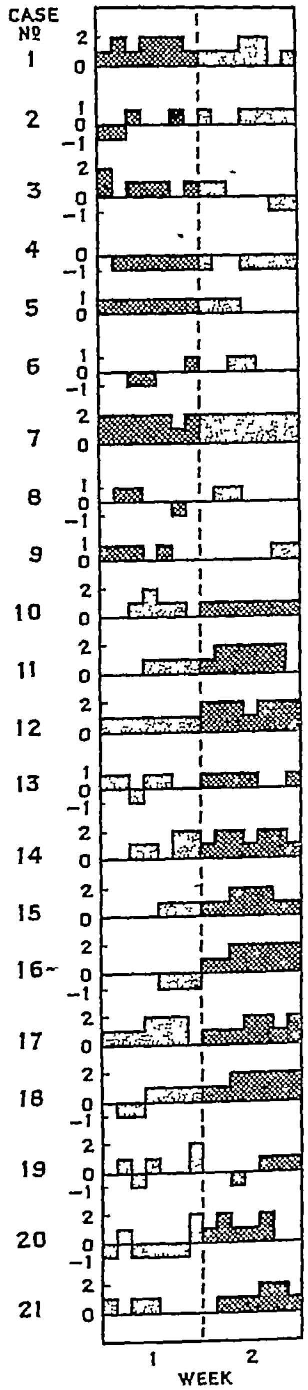

Fig 2—Results in 21 cases of lichen simplex

3 of our patients abandoned the treatment and were not included in the tabulated results They were

1 A patient with discoid eczema who complained that the ointment "burned" She was receiving the vehicle alone at the time She refused to attend again for patch testing, on the grounds that the dermatosis had cleared up with treatment for her "nerves"

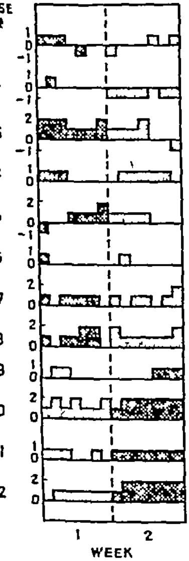
2 A patient with chronic eczematous dermatitis of the hands, of unknown cause who complained of fresh outcrops of vesicles after applying hydrocortisone ointment for three days She abandoned its use Patch tests with the hydrocortisone ointment and with the vehicle alone were negative, but when patch testing was carried out with the separate constitutents of the vehicle, a positive response was obtained to propylene glycol Her dermatitis subsequently improved

KEY TO FIGS 1–8.

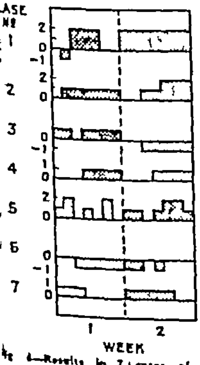
Hatched = hydrocortisone. Stippled = vehicle 2 = no itching 1 = diminished itching 0 = usual itching -1 = increasing itching lly when 2·5% hydrocortisone, with hydrous ointment as vehicle was applied. This had been specially prepared ur request.

A patient with otitis externa, whose ears became more len and exudative shortly after he began treatment with rocortisone ointment. His eyes also became swollen Cul revealed *Staphylococcus pyogenes streptococcus hæmolyticus Pseudomonas pyocyanea* Patch tests with hydrocortisone with the vehicle were negative

Malkinson and Wells (1954) did not find that secon lly infected dermatitis was aggravated by the drug The anti inflammatory action of hydrocortisone relieves itching and lessens scratching, thus diminishing bacterial contamination of the lesions and bringing about amelioration of the infective as well as of the eczematous and lichenified elements On the other hand, dermal infections with cocci (such as erysipelas boils, and ecthyma) should in theory be aggravated by hydrocortisone which has the effect of lowering the resistance of the host thus enabling the organisms to multiply (Houghton 1954 Hart 1954) This matter is still sub judice



g 3—Results in 12 cases of infantile eczema



g 6—Results in 7 cases of pruritus of anogenital region.

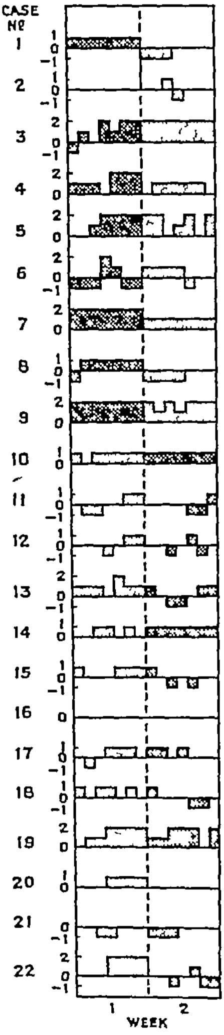


Fig 4—Results in 22 cases of Besnier's prurigo.

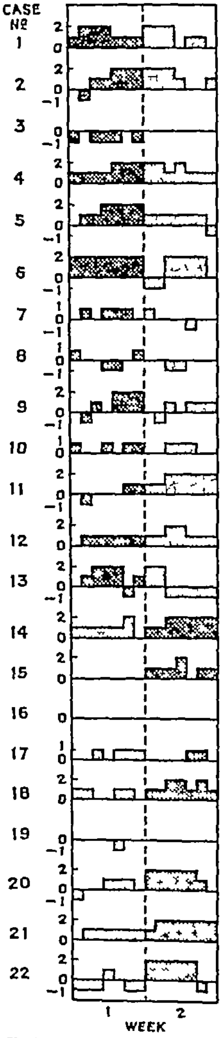

Fig 5—Results in 23 cases of discoid eczema. The 23rd patient failed to complete the trial.

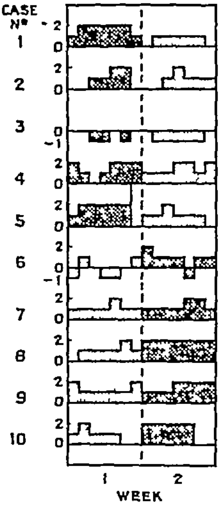

Fig 7—Results in 11 cases of otitis externa. The 11th patient failed to complete the trial.

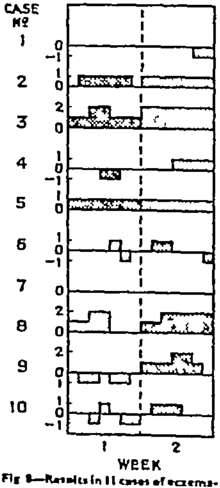

Fig 8—Results in 11 cases of eczematous dermatitis of hands. The 11th patient failed to complete the trial.

TABLE I—MEAN DAILY RESPONSE SCORES

Diagnosis	No of cases	Score with hydrocortisone	Score with vehicle
Anogenital pruritus	25	1 01	1 04
Lichen simplex	21	1 00	0 49
Infantile eczema	12	0 84	0 55
Besnier's prurigo	22	0 54	0 59
Discoid eczema	23	0 97	0 57
Idiopathic eczematous dermatitis of the hands	11	0 61	0 43
Otitis externa	11	1 28	0 79
Pruritic anogenital psoriasis	7	0 63	0 51

EFFICACY OF THE VEHICLE

In trials such as this it is always possible that the bland vehicle may have a considerable antipruritic action

Sulzberger and Witten (1952), in their early trials of hydrocortisone, noted some improvement with the ointment base alone, though less than with the ointment containing hydrocortisone McCorriston (1954), too, noted that in a number of patients *the control sites of the soft paraffin and emulgent* bases showed some improvement This was confirmed in a later study by Sulzberger et al (1953) Most of their patients were treated with hydrocortisone acetate in a non greasy base (containing zinc stearate, propylene glycol, polyethylene glycols, and water)

Robinson (1953) noted that after the condition had been *controlled by hydrocortisone, it often seemed to respond* better to other local therapy than previously

McCorriston has used hydrocortisone in four different vehicles in the treatment of infantile eczema These were a cream of zinc stearate, propylene glycol, polyethylene glycols, and water, white soft paraffin, a jelly base, and an oil in-water emulgent base Though the cream was useful in the *weeping stage, the jelly was found to be too drying* The soft paraffin or the emulgent base were preferable for dry, thick, scaly areas

In the present trial the vehicle was similar to that used by Sulzberger and Witten (1952)—namely, a non greasy polyethylene glycol base Polyethylene glycols *(Smyth et al 1950) have proved less irritant than soft* paraffin mild sensitisation reactions (faint erythema) as almost as common as with lanolin, soft paraffin, simple cerate, and simple ointment Case reports of sensitivity to polyethylene glycols are very few Strauss (1950) reported 2 cases of sensitivity to the entire group of polyethylene glycols These substances are non-ionic (Schutz 1953), they are therefore insensitive to metallic ions, and can be used both in acid and in alkaline media They dissolve or emulsify lipophilic substances and are valuable vehicles for oil soluble drugs when it is desired to bring these *into close contact* with the skin and with its folds

Results obtained with the vehicle in the present study *indicate that it is* remarkably effective by itself as an emollient and as an antipruritic agent, but its efficacy is far less than that of hydrocortisone ointment in of the skin diseases that we have studied

From the cosmetic point of view, a non greasy b of the " vanishing " type is more pleasant than a greasy *ointment* We agree with Sidi and Bourgeois Gavardi (1953) that the polyethylene-glycol base has an action superior to that of most local applications, and it has the advantages of *being æsthetically* acceptable and not necessitating dressings

TABLE II—INDEPENDENT ASSESSMENT OF EFFECT OF HYDROCORTISONE OINTMENT

Disorder	Cleared without relapse	Completely controlled	Much improved	Slightly improved	Unchanged	Worse or course abandoned
Anogenital pruritus	2	6	6	8	2	1
Lichen simplex	0	2	8	3	7	1
Infantile eczema	0	2	0	6	4	0
Besnier's prurigo	0	2	1	7	11	1
Discoid eczema	2	3	4	4	9	1
Idiopathic eczematous dermatitis of the hands	0	1	2	1	5	2
Otitis externa	2	3	2	2	1	1
Pruritic anogenital psoriasis	1	0	1	1	4	0
Total	7	19	24	32	43	7

SUBSEQUENT PROGRESS

With more prolonged treatment (without concealed control or record cards) progress has been maintained in lichen simplex, discoid eczema, anogenital pruritus, and otitis externa As extraneous events have a powerful influence on progress in infantile eczema, hydrocortisone ointment, though often helpful, may have to be assisted by sedative drugs In cases of Besnier's prurigo we *have not felt* justified in continuing treatment with hydrocortisone

INDEPENDENT ASSESSMENT

An independent observer (Dr C M Ridley) has perused the case notes and analysed the results The assessment (table II) was made on subjective impressions combined with the objective evidence recorded in the notes, it attempted to measure the effect from the beginning to the end of treatment with hydrocortisone ointment The duration of treatment varied from two weeks to several weeks In some cases treatment with hydrocortisone ointment was still in progress at the time of the assessment

CONTACT ECZEMATOUS DERMATITIS

We have observed marked relief of contact eczematous *dermatitis with hydrocortisone* ointment However, the condition does not lend itself to controlled studies, its natural course differing greatly from one person to another

Summary

Concealed trials with hydrocortisone ointment, alternated with its vehicle alone, and a longer term independent survey of results, have shown that hydrocortisone was remarkably effective in many patients with lichen simplex, discoid eczema, otitis externa, and anogenital pruritus In infantile eczema and in idiopathic *eczematous dermatitis of the hands* the improvement was less obvious In Besnier's prurigo local improvement was sometimes obtained, but the general results were poor one reason for this may have been that the ointment applied in very small quantities In itchy psoriasis of the anogenital region the results *apparently depended* on the efficacy of the vehicle

Hydrocortisone ointment is also highly effective in contact eczematous *dermatitis*, but examples of condition have not been included in these controlled

An independent observer, assessing the results, concluded that there had been distinct or complete relief in 14 of 25 patients with anogenital pruritus, in 10 of with lichen simplex, in 2 of 12 with infantile ec in 3 of 22 with Besnier's prurigo, in 9 of 23 with di eczema, in 3 of 11 with idiopathic eczematous derm *of the hands, in 7 of 11 with otitis* externa, and of 7 with itchy flexural and genital psoriasis

Only 1 of the 132 patients in the trial proved sensitive to the vehicle, but relief was subsequently obtained with hydrocortisone in hydrous ointment 1 patient complained *that the ointment caused* a burning sensation in another infection increased during treatment

We wish to thank Dr L Bernstein, of the department of physiology of the London Hospital, for his statistical guidance and constructive criticism, and Dr A E Gremeaux, of Roussel Laboratories, for his coöperation, and for supplying the hydrocortisone ointment and the inert vehicle which we

in the trial We also thank Mr D C Phillips of the maceutical department of the London Hospital, who onally supervised the concealed trial

Cholera, a disease characterised by loss of fluid ered blood volume shock and anoxia appears to be ideal condition for the study of Selye s (1950) alarm action in man However very little is known about e activity of the suprarenal glands in cholera

Rogers (1921) citing Nearne considered the high tolerance cholera patients to adrenaline as an indication of suprarenal sfunction.

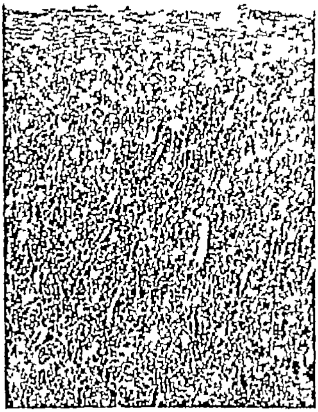

Fig. 2—Suprarenal gland in cholera showing complete depletion of sudanophil material (no black stain) Details as in fig 1

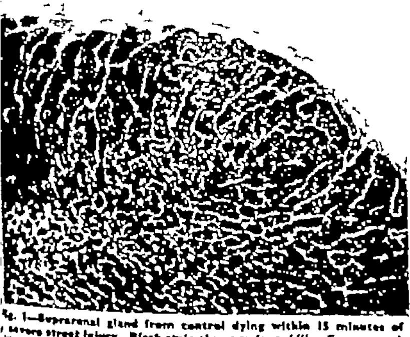
Chatterjee (1930) studied the suprarenal glands from some cases of cholera and thought the congestion of boundary zone to be related to the extreme shock of the first stage of the disease

Lahiri (1946) treated a few cases with total suprarenal cortical extract and noted some improvement of the vascular tone

We have in the past searched in vain for any significant morphological change in the suprarenals in cholera by ordinary staining methods The recent paper by Stoner et al (1953) prompted us to try their histochemical methods on our cholera materials. A preliminary report of our findings was read at the fifth annual meeting of the Indian Association of Pathologists

Materials and Methods

We studied eleven pairs of suprarenal glands from bacteriologically positive cases of cholera fatal within 48 hours after onset in the stage of shock Ten pairs of glands from patients dying within 15 minutes of injuries from street or railway accidents served as controls None of the patients was aged less than 10 years and the controls showed no gross pathological changes except those of their injuries The necropsies were done 24–48 hours after death on bodies kept in the cold chamber Five frozen sections from different blocks of each gland were prepared for the detection of neutral fat by staining with Sudan iv, of cholesterol with digitonin seen by polarised light and of ketosteroids with 2 4 dinitrophenylhydrazine No attempt was made to ascertain the weights of the glands the thicknesses of different zones or the cell-size



g. 1—Suprarenal gland from control dying within 15 minutes of a severe street injury Black stain shows sudanophilia. Frozen section 20 µ thick. (Sudan IV × 70.)

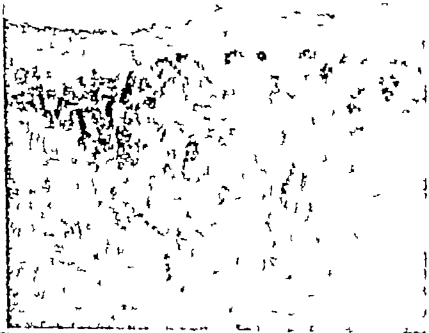


Fig 3—Suprarenal gland in cholera, showing small sudanophil islets retained. Details as in fig 1

Under the auspices of the Indian Council of Medical Research

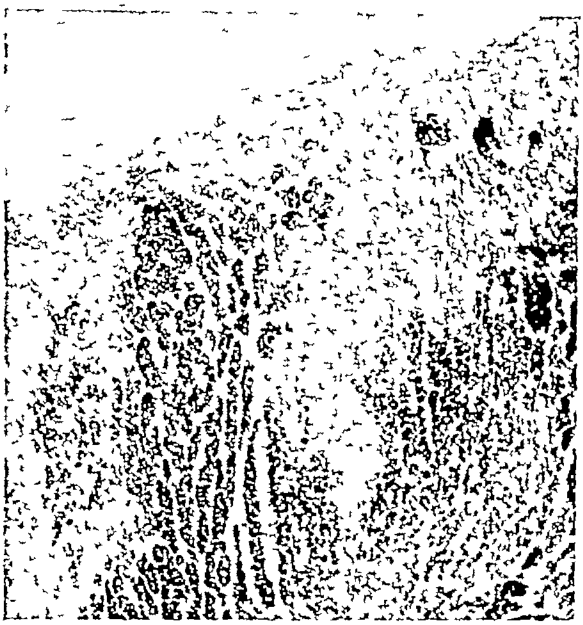

Fig 4—Patchy disappearance of sudanophil material in suprarenal gland in cholera. Details as in fig 1

Results

In four cases there was evidence of complete depletion of neutral fat from all the zones (figs 1 and 2) Only an occasional cholesterol crystal could be made out here and there Staining for ketosteroid showed a faint pale yellow coloration

In five cases neutral fat was seen to have disappeared in patches of varying extent—either wide areas still retained it, or wider areas had only small islands of it left here and there (figs 3 and 4) In one case loss of neutral fat was confined to the zona glomerulosa (fig 5) This patient received only $1^1/_2$ pints of saline solution before he died, in contrast to 4–38 pints received by other patients in 1–3 days In all these cases ketosteroid and cholesterol showed patchy distribution, but evidence of depletion of cholesterol was much more striking (figs 6 and 7)

In the 11th case all the zones retained sudanophil material while cholesterol crystals were confined to the zona glomerulosa only (fig 8)

One constant finding was that, whereas the neutral fat in the *control glands* appeared large and globular, that seen in cholera was always smaller and granular (figs 9 and 10)

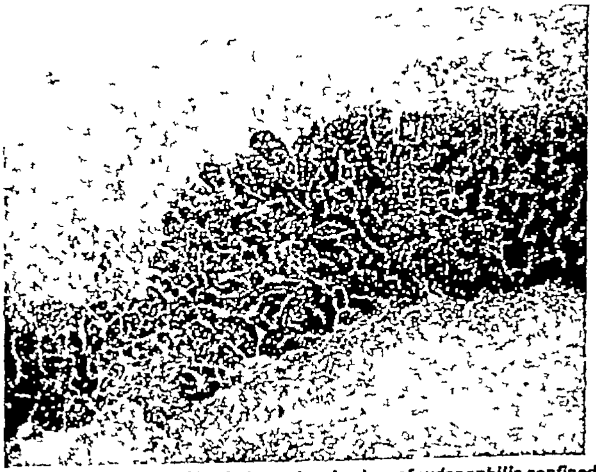

Fig 5—Suprarenal gland in cholera, showing loss of sudanophilia confined zona glomerulosa. Details as in fig 1

Discussion

This histochemical evidence of depletion of lipoid material has generally been thought to be associated with increased liberation of cortical hormone under various conditions Selye (1950) has described similar changes in his experiments on animals with non-specific alarm reaction and has related them to increased activity of the suprarenal glands under stimulation of the adrenocorticotropic hormone of the hypophysis Histochemical reactions have recently been used to investigate the functional state of the gland, but there is no agreement about their specificity Particular importance has been attached to the cholesterol content and its relative distribution An inverse correlation between *cholesterol content and secretory activity of the gland* has been well established by using stimuli of varying intensity and duration Sayers (1950) regards cholesterol as the precursor of cortical hormone, large stores being held in the suprarenal glands in readiness for emergency periods requiring enhanced synthesis of the hormone We have not estimated the cholesterol content of the glands but have attempted to form an idea from the above mentioned histochemical test, and there is good evidence that it tends to disappear in cholera Staining for ketosteroids may give an idea of the relative amount of the finished hormone available at the moment, but the significance of sudanophil material is not clear. A correlation between change in these lipoids has not always been possible, and Sayers (1950) thinks it is due to slight differences in technique We have, however, found a broadly parallel change in these three materials, although sometimes traces of cholesterol were left when neutral fat and ketosteroid had disappeared, or no cholesterol could be seen in the zona fasciculata, where sudanophil material still persisted Depletion of steroid has, however, been often greater than that of sudanophil material Ayres et al (1951) noted the same in acute infections

Fig 6—Birefringent crystals of digitonin cholesterol seen in polarised light suprarenal gland from control. From section 25 µ. (× 70)

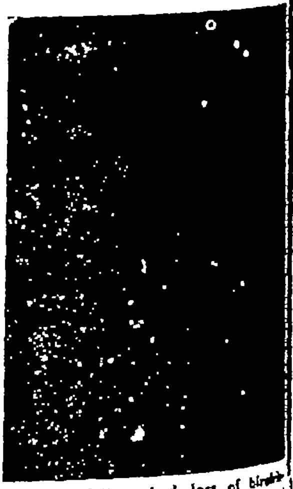

Fig 7—Well marked loss of birefringent crystals from suprarenal gland in cholera. Details as in fig 6.

In one case the zona glomerulosa was depleted of all lipoids, and in another this zone alone showed crystals f cholesterol. The former patient received only $1^{1}/_{2}$ ints of saline solution during his short stay in the ospital, and the latter received 24 pints in 46 hours It s tempting to think that the zonal picture in the two ases was caused by hyponatræmia in the former and ypernatræmia in the latter It should, however, be emembered that the blood sodium level was not stimated in any of these cases that only two such cases ere observed and that the question of zonal autonomy ill remains an enigma (Sayers 1950) so it will be rash o draw any conclusion from this observation

The over-all picture seen in cholera suggests that the uprarenal glands play an active rôle in cholera by nhanced synthesis of its hormonal products This oncept finds support in another recent observation in his laboratory (De et al. 1955) on the hæmatological hanges in untreated cases of cholera Cholera is not ssociated with suppuration or emigration of leucocytes nywhere into the tissues, yet the blood shows a leucocytosis which is much more than can be explained by imple hæmoconcentration At the same time there are eutrophilia lymphopenia, and eosinopenia Not only re the eosinophils diminished but in many cases they eem to disappear altogether from the peripheral blood. ll these facts are generally regarded today as convincing evidence of increased suprarenal cortical activity

As regards the relation of *Vibrio choleræ* or its products o these various changes, similar blood changes have been ound in our vibrio negative cases Besides, no sign of ecrosis or hæmorrhage has been seen in the suprarenal glands of cholera patients. These facts suggest that all he changes in the blood and in the suprarenal glands form art of a non-specific response on the part of the body to he associated dehydration shock and anoxia

ig. 8—Birefringence confined to zona glomerulosa in suprarenal gland of cholera patient treated with large doses of saline solution. Details as in fig. 6.

Be that as it may the functional capacity of the drenal cortex, judged by the histochemical techniques oes not appear to be the same in all these cases of holera at the time of death In four cases there was omplete depletion of all lipoids—regarded by Stoner t al (1953) as evidence of complete exhaustion Cortical ailure may reasonably be suspected in these cases though ot proved. In the others variable amounts of lipoid re still left indicating that the glands retain some tock of basic elements for responding to further corticotropic stimulation In spite of such potent suprarenal lands, cortical hormonal deficiency may have been esponsible for the fatal outcome when the failure may e located at a supra adrenal level

Sevitt (1954) used a combination of adrenaline and orticotrophin tests in fifty four cases of burns and iagnosed adrenocortical failure in five and failure of he pituitary-adrenal axis in two cases Cortisone therapy as indicated in the former and corticotrophin in the atter To clarify the therapeutic implications of our bservations in cholera further investigations into the unctional state of the two units of the pituitary suprarenal axis by serial blood-counts with these special methods up to the time of death will be necessary

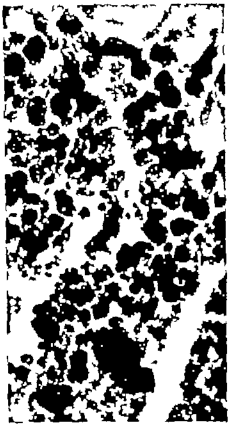

Fig. 9—Sudanophil globules in control suprarenal gland. Details as in fig 1 (× 250)

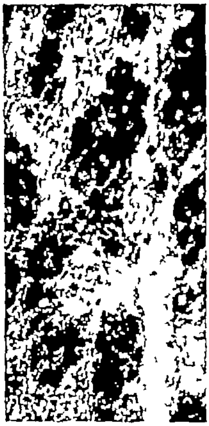

Fig 10—Sudanophil granules in suprarenal gland in cholera. Details as in fig 1

Conclusions and Summary

Evidence of various degrees of depletion of cortical lipoids suggests an active rôle of the suprarenal cortex for enhanced synthesis of its hormones in response to the stress of dehydration, shock, and anoxia of cholera

Further work to inquire into the functional state of the pituitary suprarenal system in cholera is called for

We wish to thank Dr A K. Duttagupta for permission to publish and Mr M Mazumder for the photomicrographs.

CLINICAL EXPERIENCES WITH
SOFT-TISSUE PLACENTOGRAPHY

ROBERT PERCIVAL

M.D Belf F.R C.S.I., D.M.R
ASSISTANT RADIOLOGIST

THE LONDON HOSPITAL

OUR object is to draw attention again to the advantages of soft tissue placentography which in our experience, has proved a safe and reliable way of establishing the position of the placenta

The work of Reid and of Whitehead on the radiological aspects of soft tissue placentography should leave no doubt as to its reliability simplicity and safety But essential for success is close collaboration between radiologist and obstetrician with interest and confidence equally distributed.

The method is valuable for several reasons. Firstly, the position of the placenta can almost always be seen or be deduced without any other examination It is not disturbing to the patient and in selected cases it may be used for outpatients Secondly it saves beds. Now that antepartum hæmorrhage is managed conservatively patients may have to stay in hospital for as long as six weeks before the fœtus is judged mature enough to risk premature delivery after examination under anæsthesia Soft tissue placentography can greatly reduce such use of valuable beds in non-toxic antepartum hæmorrhage, once placenta prævia has been excluded and bleeding has ceased the patient can safely be sent home Thirdly, it saves patients from wasting time unnecessarily in hospital No longer need a patient who has bled a little at 32 weeks, but is otherwise normal, be kept in hospital for weeks If bleeding is very slight or has stopped, it is quite easy to decide the position of the placenta within half an hour of the patient's admission It cannot be denied that up to the 34th week of pregnancy the method is not always as accurate as it is after this time, this applies to the borderline case in which the placenta appears to dip just beneath the brim, especially when it is anterior Radiography two weeks later will often show the placenta wholly above the brim, as if it had risen as the lower segment became more differentiated Finally, soft tissue placentography is a useful means of finding out whether the position of the placenta, even when in the upper segment, is responsible for a particular presentation or lie (Stevenson 1951) Moreover, it often explains why version has not been successful, and if a second attempt at version is made the dangerous placental site can be avoided

Recent Work

Chief credit for redirecting attention to this essentially simple technique must go to Reid (1949) and Whitehead (1953) The methods involving artificial-contrast media (amniography, cystography, and intravenous placentography) have been examined thoroughly by these workers, who found that they lacked simplicity and accuracy and accordingly were unsuitable for routine use Reid and Whitehead independently followed the lead of Snow and Powell (1934) and others, by making the fœtus serve as its own contrast medium and by deducing the position of the placenta from its displacement of the fœtus The need for such a technique was emphasised when Moir (1944) proved that the uterine wall, the liquor amnii, and the placenta have identical radiographic density, and that consequently no hope could be held out for ordinary soft-tissue methods in locating the placental site

In addition to the valuable radiographic density of the fœtus, use is made of another of its properties—its molecular density, which is greater than that of the fluid surrounding it The fœtus sinks to the lowest point of the amniotic cavity, and by changing the patient's position any area of the uterine wall can be examined against the outline of the fœtus

Clinical Indications for Placentography

275 cases were studied over the three year period 1951–53 At first the patients were carefully selected, but when we became more familiar with the technique we used it more widely During the early part of the trial the method was not used by every member of the unit, so the series cannot be said to include all examples of the different clinical problems which we investigated After the first six months all patients suspected on clinical grounds of having placenta prævia were submitted to placentography The following list gives an idea of the type of case where we considered it an advantage to discover the position of the placenta

(1) Antepartum hæmorrhage, where the precise diagnosis is in doubt
(2) Unexplained displacement of the presenting part
  (a) High head
  (b) Recurrent malpresentation.
(3) Cases of (1) and (2) combined
(4) Unexplained breech presentations
(5) Unexpected failure of version
(6) Cases due for surgical induction (especially by the Drew Smythe catheter) in which the presenting part is unengaged
(7) Other indications

(1) *Antepartum hæmorrhage, where the precise diagnosis is in doubt*

This is by far the most important indication. When local causes have been excluded there remain, for practical purposes, only two conditions to differentiate—accidental hæmorrhage and placenta prævia Placentography will immediately indicate the position of the placenta There are other signs of diagnostic value when the placenta occupies the lower segment, especially in the last few weeks of pregnancy, but before this the presentation is not expected to be stable, and it is in these very cases, especially when the placenta is on the anterior wall, that physical signs are equivocal and placentography is of the greatest value

Again, bleeding thought to be caused by toxæmia may in fact be due to placenta prævia In this series the combination of toxæmia with placenta prævia was found only twice, and in neither instance was there any evidence of accidental hæmorrhage Bender (1953), on the other hand, found that toxæmic accidental hæmorrhage accounted for the bleeding in 10 of 102 cases of placenta prævia

(2) *Unexplained displacement of the presenting part*

(*a*) *High head*—In the last few weeks of pregnancy, if the head is high and it cannot be pushed into the pelvis, and if no other cause is found, then placentography would be helpful

(*b*) *Recurrent malpresentation*—The indications here are similar Stevenson (1951) has emphasised the high incidence of a completely fundal or lower-segment location of the placenta in persistent transverse lie

(3) *Case of (1) and (2) combined*

One would expect to find placenta prævia in these circumstances, yet of 38 cases of antepartum hæmorrhage associated with high head or unstable presentation only 13 had placenta prævia, in the remaining 25 the placenta was situated normally One of the criticisms levelled at radiological placental localisation has been that with placenta prævia the diagnosis can be made by abdominal examination Undoubtedly experience and an intelligent application of clinical methods will result in relatively few mistakes The patient who is known to have bled is of course admitted to hospital, but if she has not the obstetrician may become dangerously complacent unless an easy and accurate means of detecting a placenta prævia is available Moreover, the very knowledge that unexplained non engagement of the head can exist in the absence of placenta prævia may provide a ready excuse for not investigating further, and so defeat the most effective means of lowering the fœtal and maternal death rate from placenta prævia—namely, that of diagnosing it and admitting the patient to hospital before any bleeding has taken place

(4) *Unexplained breech presentations*

Stevenson (1951) has shown that the commonest site for the placenta in persistent breech is the uterine cornu, and he has suggested that this causes such alteration in the shape of the uterine cavity that the fœtus is accommodated more readily as a breech In the few cases investigated we have confirmed the preponderance of the cornual position and have found placenta prævia relatively infrequently (table III)

(5) *Unexpected failure of version*

It is not uncommon to fail unexpectedly to turn a breech that has been judged suitable for version, even after it has been disengaged There are probably several reasons for this, but the most likely is that the bulk of the cornual placenta impedes the passage of the head or so obscures the upper pole that it cannot be grasped easily If further attempts at version are to be made, it is clearly of value to know on which side the placenta lies, so that it can be avoided It is even more important to exclude o presence of placenta prævia (unusual though it is th a breech) before making further attempts, especially anæsthesia is contemplated

) *Cases due for surgical induction in which the presenting rt is unengaged*

A not uncommon type of case is that in which there toxæmia necessitating induction but the head is not gaged though it can be pushed in In such circumstances acenta prævia can often be excluded clinically but it is ll possible for a placenta on the posterior wall to extend w enough to be disturbed by a Drew Smythe catheter bviously, it would be valuable to know that the placenta elsewhere and out of range (only then, indeed should a Drew Smythe catheter be used) Bender s figures 953) relating to the cause of bleeding in placenta prævia aphasise the danger of using this instrument in unsuitle cases

) *Other indications*

(a) *Previous classical cæsarean section* —Since rupture the uterus is thought to be more common if the acenta is implanted on the uterine scar it is as well to low the placental location in the latter weeks so that e risk may be lessened by admitting the patient to spital before term

(b) *Situation of placenta when it is prævia.*—When acenta prævia has been diagnosed by placentography e actual extent of the placenta on the anterior wall is own before operation and the technique can be anned so as to minimise maternal and fœtal blood loss. acentography may also be considered a useful prelimin y when cæsarean section is to be done under local algesia

(c) *Antepartum hæmorrhage especially before the 30th ek* —If placentography is done routinely a radiograph the fœtal skeleton is automatically available Gross ngenital abnormalities (which are more common when e placenta is prævia) may be seen and useless con rvative management for the sake of the fœtus thereby oided

Results

PLACENTA PRÆVIA

Of 50 cases of placenta prævia (table I) 1 was missed, ving a 2% error for placenta prævia The mistake was ade early in the series and was due entirely to inex rience in interpretation Nothing similar has happened since and in cases of significant placenta prævia in the last 6 weeks of pregnancy the error should be nil Where the diagnosis is on the borderline this should be made clear in the radiological report Such cases are found mostly when placentography is undertaken too early in the last trimester, before the lower segment has become well formed In a few cases the condition is truly border line—that is to say, the head is displaced only a little from the symphysis or promontory when the placenta extends down the anterior or posterior wall The level of the upper boundary of the lower segment is undoubtedly variable but in this technique it is assumed always to be at the pelvic brim The vagueness of this important landmark makes it all the more desirable for radiologist and obstetrician alike to be guarded in the special circumstances already mentioned before stating categorically that the placenta does not reach into the lower segment, and to be prepared to make a diagnosis of ' borderline placenta prævia

There were no maternal deaths

In this series the radiological diagnosis of placenta prævia was in each instance confirmed or refuted before during or after delivery by examination under anæsthesia, cæsarean section or postpartum intra uterine palpation or by careful inspection of the placenta and membranes Neither of the last two methods is entirely satisfactory In the first place, owing to uterine retraction the placental edge either separated or still attached will often feel uncommonly low at the beginning of the third stage Where possible these findings should therefore, always be confirmed by inspection of the placenta and membranes after delivery Secondly the inspection of the placenta and membranes as a means of confirming the placental level will only be of value when the hole in the membranes has not been grossly enlarged and when the gestation sac has been expelled intact Again after measuring the distance between the placental edge and that of the hole doubt often remains as to whether the placenta did in fact reach the lower segment Where the hole was of average dimensions a distance of less than 2 in immediately placed the case in the category of placenta prævia We therefore conclude that if the diagnosis is not made before delivery in doubtful cases, the doubt will seldom be removed by any postpartum method of examination including that of injecting the placenta via the umbilical cord with radio-opaque substances (Radio-opaque substances were not used in this series for the method was regarded as having no special merit) Finally even by examining a patient under anæsthesia before delivery it would not always be possible to feel the edge of a placenta that just reached into the lower segment, especially when the cervix is not well drawn up and when the placenta is posterior

Clinical Features

The largest group is that of antepartum hæmorrhage alone because the bleeding most commonly began before the fœtus was big enough to be regarded as unstable or unduly high The earliest diagnosis was made at 30 weeks yet strangely enough an even earlier one (at 26 weeks) was made in the next group of antepartum hæmorrhage and high head &c It might be argued that this pregnancy was not far enough advanced for the presentation to be significant yet in central placenta prævia (as this one was) the fœtus will often be found unduly high even at a comparatively early stage The difficulty of trying to rely on abdominal palpation alone to diagnose placenta prævia even when there is both antepartum hæmorrhage and a high presenting part is well shown by comparing the number of cases of antepartum hæmorrhage and high head in table I with that in table II In the placenta prævia series only 13 out of 50 (or just over a quarter) fell into the antepartum hæmorrhage and high head ' group whereas in the other cases there were 25 out of 84 (or slightly less than a third)—figures which are distinctly comparable.

Placenta prævia was diagnosed before any bleeding took place in 14 out of 50 cases (or nearly a third), these having been radiographed purely because of the abnormal relationship between the presenting part and the pelvic brim This suspicious sign was acted on with positive findings as early as the 32nd week in 1 instance (and there were 3 others before the 36th week), and as late as the 40th week in another In 7 patients antepartum hæmorrhage was avoided entirely, even though the average maturity at diagnosis in these patients was 35 weeks, and 1 had a 4th-degree placenta prævia No fœtus was lost, and their average birth-weight was 6 lb 11 oz

Accidental Hæmorrhage

Although pre eclamptic toxæmia was found to accompany placenta prævia on 2 occasions, there was no evidence that the bleeding was accidental In fact 1 of these patients had no bleeding at all she had a 4th-degree placenta prævia and was delivered at term (by cæsarean section) of a thriving 8 lb 3 oz baby

Examination under Anæsthesia

This was carried out on 10 patients in whom placenta prævia had been diagnosed radiographically It was done for two reasons (1) to check the radiological findings early in the series (later it was used only in borderline cases), and (2) in the lesser degree of placenta prævia, especially anterior ones, to decide on the best method of treatment Disproportion due to posterior placenta prævia is a definite indication for cæsarean section, as was emphasised by Stalworthy (1951)

Fœtal Abnormalities

The incidence of fœtal abnormalities is known to be raised in placenta prævia Macafee's (1945) figure was 3 4% In this series two developmental abnormalities were found (a hare-lip, and a meningocele) In both cases the placenta prævia was of first degree

Average Birth-weight

The conservative management of antepartum hæmorrhage, particularly when it is due to placenta prævia, is now so well established as to require no further com mendation here The average birth-weight of 6 lb 11 oz in our 50 cases of placenta prævia is ample proof of the wisdom of such a policy

Fœtal and Neonatal Deaths

One of the aims in the modern management of placenta prævia is to reduce fœtal and infant loss without adding extra risk to the mother The mortality-rate of 16% in this series compares favourably with that in other reported series The average birth-weight of the fœtuses and infants lost was 5 lb 5 died after birth, the only abnormal finding being prematurity 3 were stillborn—1 from prolapse of the cord, 1 macerated from placental infarction, and 1 from the cord being tightly round the neck Table I shows that the loss was fairly evenly divided between the different degrees of placenta prævia It is unfortunate that 3 of the neonatal deaths followed cæsarean section In 6 of the patients concerned, active measures had to be undertaken to combat recurrent severe bleeding

Treatment

There were 31 cæsarean sections 14 were for 4th-degree and 3 for 3rd-degree placenta prævia Of the 8 done for 2nd degree, 1 was for a breech in an elderly primigravida, 3 were for posterior placenta prævia with apparent disproportion, and 4 were for excessive bleeding after artificial rupture of the membranes had failed to stop it In the other 2nd degree cases, bipolar version was done once when artificial rupture of the membranes did not stop the bleeding, simple artificial rupture of the membranes was also done, and in the remaining 3 cases no treatment was required 6 cæsarean sections were done for 1st-degree placenta prævia—2 for excessive bleeding, 2 for unstable presentation, 1 for associated diabetes mellitus, and 1 for prolapse of the cord

Maternal Deaths

There were no maternal deaths associated with pla prævia

Incorrectly Diagnosed and Borderline Cases

Case 1 —A para 5 with antepartum hæmorrhage, and fœtal head at 34 weeks Placentography showed a post placenta , the head was displaced significantly, but thi erroneously thought to be due possibly to clot B continued, and examination under anæsthesia showe marginal placenta prævia Artificial rupture of the mem and bipolar version stopped the bleeding, but an imm infant of 4 lb 3 oz was delivered, which died after hours This case was one of the earliest in the series Th mistake was not in technique but in interpretation, and w due entirely to inexperience

Case 2 —A para 2 with antepartum hæmorrhage at weeks Placentography revealed no significant displacem of the head, and it was reported as showing "no evidence placenta prævia " The patient subsequently had a norm labour with no further bleeding, but postnatal inspection the placenta suggested that it was low lying—possibly degree The infant weighed 6 lb 1 oz and did well.

Case 3 —A primigravida with a high head at term. Pla tography showed an anterior placenta and no significant placement *Normal delivery took place with no bleeding*, there was a 40 oz postpartum hæmorrhage Postpa intra-uterine examination suggested that the placenta just reach into the lower segment anteriorly and was po a 1st-degree placenta prævia The infant weighed 10 lb. and did well

Case 4 —A primigravida with antepartum hæmorrhage a high head at 35 weeks Placentography showed a post placenta and there appeared to be no significant displace from the promontory to suggest that the placenta reached *the lower segment The patient was examined* under thesia, and a thin edge was thought to be felt high up teriorly A 5 lb 9 oz infant was delivered spontaneous and it did well. There was no report of a postpartum inspe of the placenta and membranes to confirm this case

TABLE II—FEATURES OF 84 CASES IN WHICH ANTEPART HÆMORRHAGE WAS NOT ASCRIBED TO PLACENTA PRÆV

Remarks on diagnosis
  Placenta prævia correctly excluded
  Placenta prævia erroneously diagnosed

The only serious error in these so-called missed “ cases, ’ s made in case 1 and was due to inexperience in terpretation None of the other 3 behaved subsequently e placenta prævia cases and if in fact they were y were not of significant degree and would be correctly sed as borderline only No fœtus or mother suffered a result of the error for although the baby in case 1 d, the negative radiographic findings encouraged the tinuation of conservative treatment to avoid pre turity It was further bleeding that caused the birth a fragile premature infant

ANTEPARTUM HÆMORRHAGE NOT DUE TO PLACENTA PRÆVIA

There were 84 cases of antepartum hæmorrhage not e to placenta prævia (table II) In 82 a correct diagnosis s made by radiography leaving 2 cases incorrectly gnosed 1 was a borderline case at the 39th week, d little time was wasted by the patient in hospital. e other, unfortunately spent four weeks in hospital necessarily, through an error due to inexperience in chnique Of these 84 cases the absence of placenta ævia was confirmed in 45 (table II) All the other cases haved quite normally and gave no indication of low plantation

use of Antepartum Hæmorrhage

In only 3 patients were there signs of toxæmia, and in ch instance examination of the placenta after delivery ongly supported a diagnosis of toxæmic accidental morrhage It is significant that the commonest sociation was with external cephalic version The use of the bleeding was not found in 65 of the patients

ition of the Placenta in the Upper Segment

It was thought that non toxæmic antepartum hæmor age might be associated with the position of the placen l site A likely position would seem to be the anterior erine wall reaching nearly to the pelvic brim ; there e placental site would be vulnerable to trauma and be ar enough to the cervix for the blood to escape readily ble III shows that the commonest site for the placenta non toxæmic antepartum hæmorrhage is, in fact the terior wall extending to the fundus the anterior all is the next commonest

ditional Clinical Signs

As might be expected bleeding was the only abnor al feature in over two-thirds of the cases We have ready drawn attention to how often bleeding and lative displacement of the presenting part can be found ether in the absence of placenta prævia Much portance is attached to this observation for dangerous complacency or over anxious conservatism may result if the precision and safety of soft-tissue radiography is denied both to patient and clinician

Average Stay in Hospital

If by staying in hospital a patient is doing good for herself and for her fœtus, then it would be wrong to suggest that she go home But there is no evidence that in the absence of other symptoms and signs, there is any advantage in keeping patients in hospital once placenta prævia has been excluded and once bleeding, which is usually slight, has stopped This belief determined our policy in this series. Even so, the average stay in hospital before the 36th week was reached proved to be as much as 11 days this relatively high figure is largely explained by our having to keep in patients who bled too early for placenta prævia to be excluded radiographically Even though in 1 instance placenta prævia was excluded correctly at the 26th week it is unusual to be able to give a positive diagnosis before the 34th The arbitrary time of the 36th week was decided on because those who diagnose placenta prævia by passing a finger through the cervix under anæsthesia usually wait until then to do so

Reckoned Average Time Saved

The saving of 8 days in hospital seems small enough, but with many patients the bed saving is considerable Those who doubt the value of soft tissue placentography say that this aspect of the management should be discounted ; but it is of real and practical importance both to these patients and to those who are waiting to occupy the beds.

Average Birth-weight

This was 6 lb 6 oz —lower than the reported average for placenta prævia

Fœtal and Neonatal Deaths

7 fœtuses and infants were lost giving a figure of 8 3%—about half that for placenta prævia 1 at least of these cases could hardly have had any connection with antepartum hæmorrhage the fœtus, said to have been 6 weeks postmature and weighing 11 lb died during and as a result of a very difficult delivery The other deaths cannot be attributed to our policy of discharging patients who had bled but in whom placenta prævia had been excluded radiographically since all the patients concerned were kept in hospital from the time of bleeding until they were delivered.

Fœtal Abnormality

No developmental abnormality was found in any fœtus in this group

Maternal Death

The only mother lost died some 2 months after delivery from ovarian carcinoma with pulmonary metastases

Incorrectly Diagnosed and Borderline Cases

Case 5 —An elderly primigravida with persistent breech presentation at the 34th week and a little bleeding after an attempt at version had failed. Placentography suggested posterior placenta prævia of significant degree but subsequent cæsarean section at term for the presentation revealed an anterior placenta in the upper segment This was again very early in our series and before we began to use the tilted lateral view in doubtful cases. A healthy 7 lb 10 oz. baby was delivered. (Eighteen months later significant posterior placenta prævia was again diagnosed in this patient s second pregnancy at the 34th week, breech again presenting This time the tilted lateral view was taken and subsequent cæsarean section proved the diagnosis correct)

Case 6 —A para-5 with antepartum hæmorrhage and an unengaged head at the 39th week. The placentographic films were poor in quality and a full view of the uterus was not available A borderline posterior placenta prævia was diagnosed. Examination under anæsthesia was done but no placenta was felt (No postpartum examination or inspection of the placenta and membranes was recorded to confirm this finding) A healthy 7 lb 13 oz infant was subsequently delivered

HIGH HEAD, BREECH, OR UNSTABLE PRESENTATION, &c

The primary indication for placentography in this group (table III) was either an unduly high presenting part, or an unstable presentation suggesting the possibility of a low-lying placenta, in the absence of any other detectable cause Mostly the patients had reached the last month of pregnancy, but in some placenta prævia was suspected well before the 36th week, solely on the relationship of the presenting part to the brim As table I shows, 1 case of placenta prævia was suspected and proved by radiography as early as the 32nd week The patients who had a pelvic tumour were radiographed both to test the technique in these circumstances and to exclude the co-existence of placenta prævia Of 113 cases, radiographic localisation of the placenta was correct in 109 In only 1 case was the diagnosis said to be incorrect

Case 7 —A para 3 with an unstable presentation at 36 weeks Posterior placenta prævia was diagnosed by placentography, but near term the fit of the head threw doubt on the diagnosis, so artificial rupture of the membranes was done to stabilise the presentation When labour began, bleeding was so severe that cæsarean section was undertaken. The surgeon, however, was of the opinion that the placenta did not reach the lower segment No cause for the bleeding was suggested, and we offer no other explanation There were no signs of toxæmia, and a healthy 7 lb 2 oz infant was born

The other 3 cases were essentially borderline 1 of them, case 3, has already been discussed

Case 8 —A para 2 with a very unstable presentation at 35 weeks Placentography was reported as showing a minor degree of posterior placenta prævia There was no antepartum hæmorrhage or any departure from normal in the subsequent labour at term, when a healthy 6 lb 8 oz infant was delivered No postpartum intra uterine or placental examination was recorded This, therefore, must rank as an error in diagnosis, *although it is possible that such a minor amount of placenta* dipping below the brim might either have been carried up later by uterine growth, or been so slight as to cause no trouble

Case 9 —A *primigravida* with a high head at 39 weeks Placentography suggested a minor degree of posterior placenta prævia, because of slight forward displacement of the head and the placenta occupying the posterior wall No bleeding took place during labour, which began at term, but the head engaged slowly Delivery was uneventful Unfortunately there is no record of examination after labour

No mother or fœtus was lost as a result of these debatable errors No gross mistake was made in missing significant placenta prævia The errors, as they should be in this work, were rather those of commission than omission When there is doubt, "placenta prævia" should be diagnosed Just over half of the cases were confirmed by one or other of the usual methods In the remainder there was no departure from normal to suggest a low-lying placenta The different reasons for the ill-fitting or abnormal presenting part are shown in table III In about half no cause was found This is too high a proportion and simply means that such common conditions as multiparity, occipitoposterior, pelvic inclination, and hydramnios have not been recorded in the notes

Table III also shows the comparative rarity of breech presentation in placenta prævia or contracted pelvis and pelvic tumour on the one hand, and the significant coincidence of cornual implantation and breech presentation on the other Of the 35 cases of breech presentation investigated, the placenta occupied the cornual position in no less than 24 In our series, as in Stevenson's (1951), this position was the commonest finding associated with breech presentation, and it is the most probable cause of persistent breech presentation The placental position in the [illegible] cases is shown in table III In 1 case there was both pelvic tumour and cornual implantat but precedence has been given to the tumour as the c of the breech

Further Points

Transverse or Oblique Lie

The very essence of soft tissue placentography is t use the contrasting outline of the fœtus to show by displacement the position of the placenta Unless lie is axial, with the lower pole over the brim, the imp tant brim area cannot be examined accurately, and the obstetrician should be present in the X ray depart to correct the lie immediately before placentography

Pelvic Tumour and High Head

Obviously the diagnosis of pelvic tumour will be ma by clinical examination, but it is not by any means e to exclude the co existence of placenta prævia clinical Even when the radiologist knows of the presence of pelvic tumour, if the placenta extends well down th posterior wall it is not always possible to be sure that of the head displacement is not due partly to place prævia The same is true when the head is displaced a rectum grossly distended by fæces The difficulty d not arise when the placenta is on the anterior wall fundus, for the radiologist can then diagnose the of the displacement with confidence In practice, fr the aspect of delivery, it is of no importance to disting between tumour and placenta prævia, because cæsar section will be needed in both However, for safe an natal management it is important to know of possibility of placenta prævia

Early Diagnosis

Before about the 34th week precise diagnosis can made only when the placenta is implanted mainly are the fundus, or mainly in the lower segment Even wh the placenta appears to extend from the anterior posterior walls into the pelvis, at this early stage it impossible to predict how much will remain there as th uterus grows and the lower segment forms Natura if a case is borderline so early it will almost certa become negative for placenta prævia at a later date wh further placentography should be done A correct dia nosis was made in 5 of our patients by the 30th wee In 3 placenta prævia was excluded, in 2 major place prævia was discovered, and both subsequently need cæsarean section

Placenta Prævia and the Presenting Part

The relationship of the presenting part with the pe brim is used both clinically and radiologically to dia placenta prævia, and the more experienced a clini becomes the closer will he approach the precision placentography, yet it is only in the more extre forms of placenta prævia that he is likely to achieve comparable degree of success Similarly, it is only wh the presenting part is deeply engaged and can be palpa readily through the fornices that placenta prævia ca be excluded as the cause of bleeding in a particu patient In between these extreme examples are fou the majority of cases of antepartum hæmorrhage, a clinically there must be doubt about the position of th placenta Even when the head can be engaged read at term there can still be significant placenta præv The following case is an example of this

Case 10 —A para 1 had a little vaginal bleeding at ter The head was resting in the brim and could be eng readily The placentography report stated there was signific displacement compatible with the presence of posterior plac prævia Cæsarean section was done and a posterior mar placenta prævia was found

Radiological Technique

The technique used was essentially that described b Reid (1949) and by Whitehead (1953), but we reduc the number of films taken to two—an anteroposterio standing lateral which included the whole of the s and the pelvic inlet In some a third view was d—the tilted lateral where the standing lateral s apparent forward displacement Very occasionally views may be required in cases of hydramnios

gh kilo voltage (115–120 kV) is used for lateral . Development is cut to 3½ min to avoid over ening of the part of the film which shows the ior wall

o patient must empty the bladder immediately e examination If the rectum is too full of fæces procedure may have to be repeated.

Summary

lt tissue placentography is a practical method of ting the placental site The margin of error is iderably less than with clinical methods.

advantages are greatest in the conservative manage t of antepartum hæmorrhage

cases of major degree placenta prævia the hazards gital exploration of the lower segment can be avoided gether Only in lesser degree or borderline placenta ria, in which the risk of severe bleeding is propor ately less, may examination under anæsthesia be led, either for final diagnosis or treatment.

he method has proved particularly useful in patients ected of having placenta prævia before they have l.

hat certain placental positions may cause persistent ech presentation has been confirmed by our observa s No association was found between the placental and accidental antepartum hæmorrhage

TREATMENT OF ADRENOGENITAL SYNDROME

WITH CORTISONE AND ŒSTROGEN

C N ARMSTRONG
M.D Durh F.R C.P D.P.H
PHYSICIAN ROYAL VICTORIA INFIRMARY
NEWCASTLE UPON TYNE

In cases of adrenogenital syndrome presenting female udohermaphroditism due to hyperplasia of the adrenal nds, continuous treatment with cortisone reduces the ical masculine features and the urinary excretion 17 ketosteroids and promotes the development of inine characteristics (Wilkins et al 1950 1951 1952, Vines and Dods 1954) To obtain this result large doses of cortisone (100–200 mg daily by mouth) may have to be given, and this presents difficulties where supplies of cortisone are restricted

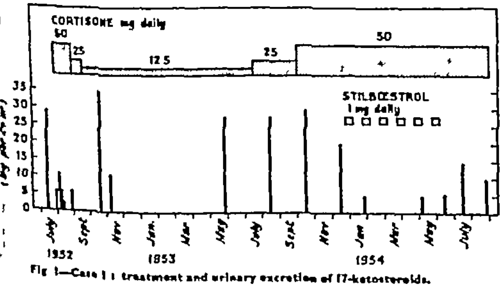

Fig 1—Case 1 : treatment and urinary excretion of 17-ketosteroids.

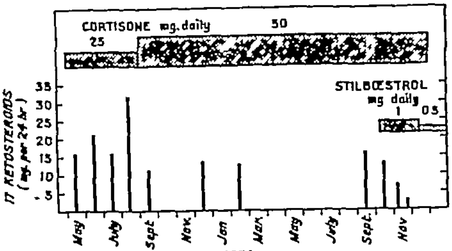

Fig. 2—Case 2 : treatment and urinary excretion of 17-ketosteroids

Treatment of such cases with œstrogen alone produces neither clinical improvement nor reduction in the excretion of 17 ketosteroids. In the following three cases, however combined therapy with œstrogen and cortisone was successful.

Case 1 —*A girl aged 10 years, was admitted to the Royal* Victoria Infirmary Newcastle upon Tyne with male body contours, severe hirsutism pubic hair of male distribution, undeveloped *breasts, and urinary excretion* of 17 ketosteroids 36 mg per 24 hours A congenitally large clitoris had been amputated

Laparotomy revealed uterus vagina, and ovaries Right adrenalectomy was performed but produced no improvement

Treatment with oral cortisone was begun with 50 mg daily in 1952, when the patient was 16 and the urinary excretion of 17 ketosteroids was reduced from 29·0 mg to 2 8 mg The dosage of cortisone was reduced to 25 mg and later 10 mg daily with no change in the clinical picture The excretion of 17 ketosteroids increased to 30 mg ; so *the cortisone dosage was increased to 50 mg daily* When the excretion of 17 ketosteroids was 21 mg under this dosage of cortisone I prescribed (for acne) 1 mg of stilbœstrol *daily for 14 days followed by 14 days without stilbœstrol,* the dosage of cortisone remaining 50 mg daily The excretion of 17 ketosteroids decreased rapidly to 4 5 mg in 24 hours I increased the dosage of stilbœstrol to 2 mg daily and then stopped it whereupon the urinary excretion of 17 ketosteroids immediately began to increase (fig 1) Coincident with the decrease in excretion of 17 ketosteroids there was clinical improvement

Case 2 —*A girl aged 9 was admitted to the Royal Victoria* Infirmary with a deep voice a hypertrophied clitoris, well developed pubic hair; the vagina was present Urinary excretion of *17 ketosteroids* 23 6 mg per 24 hours Left adrenalectomy did not produce any clinical improvement

Treatment with cortisone was started when the patient was aged 12 and her excretion of 17 ketosteroids was 10 mg per 24 hours. The dosage was 25 mg daily and was later increased to 50 mg daily The excretion of 17 ketosteroids fluctuated somewhat but the smallest amount excreted was 11 mg in 24 hours and the girl's breasts began to develop when the excretion of 17 ketosteroids was 15 3 mg Stilbœstrol 1 mg daily was prescribed in addition to the 50 mg of cortisone daily and the excretion of 17 ketosteroids decreased to 6·8 mg and later 2 3 mg per *24 hours (fig 2) Menstruation was also* established.

Case 3 —In this girl an enlarged clitoris was found at the age of 1 year and pubic hair began to grow at the age of 2½ years In 1953 when she was aged 14 treatment was started with oral cortisone 50 mg daily The excretion of 17 ketosteroids decreased from 23 0 mg per 24 hours to 12 2 mg *and later* to 7 8 mg but increased again to 10·5 mg The breasts began to develop and menstruation

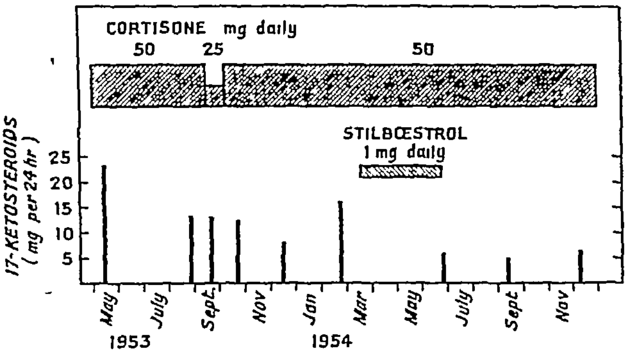

Fig 3—Case 3 : treatment and urinary excretion of 17-ketosteroids

was established With the dosage of cortisone kept at 50 mg daily stilbœstrol 1 mg daily was prescribed, and the urinary excretion of 17 ketosteroids decreased to 6 0 mg per 24 hours (fig 3) Stilbœstrol therapy had to be stopped then because of heavy menstrual bleeding

These cases show that, in the treatment of female pseudohermaphroditism, administration of œstrogen and cortisone is more effective than cortisone alone in reducing a high urinary excretion of 17-ketosteroids

MASSIVE BLOOD-TRANSFUSION THROUGH THE CEPHALIC VEIN

E G Dolton
M B Lond , F R C S
THORACIC SURGEON, ROYAL HOSPITAL, WOLVERHAMPTON

Patients undergoing major thoracic surgery may need very rapid transfusion of considerable quantities of blood Cannulation of the internal saphenous vein at the ankle leads to a disappointingly slow flow In the commonly favoured lateral position this may be partly due to compression of the saphenous vein at the knee and in the thigh by the opposing limb or an intervening pillow, and also possibly the opened chest and relaxed abdominal muscles lessen the negative pressure responsible for normal systemic venous flow Needling of an arm vein is more effective but often unsatisfactory Intra-arterial transfusion gives a rapid replacement of blood lost by major cardiac or vascular injury but is not easy to do, requires a special pump and expert medical and leads to an excess of potassium in the (Melrose and Wilson 1953)

of cephalic vein in intermuscular groove.

What is wanted is a large cannula inserted into a superficial vein reasonably near the heart No the inferior vena cava is of use, but the external vein and the cephalic vein near the shoulder satisfy criteria Use of the external jugular would lead to a on the neck , therefore the cephalic vein is to be I was encouraged to use this vein by Dr N H then casualty registrar to this hospital, who told had given infusions through the cephalic vein successfully in cases of burns

My assistants and I have cannulated the cephalic in over 100 cases, in the past twelve months. The runs very freely, venospasm has not occurred, and pint of blood can be completely transfused within minutes without any form of pressure The vein is *thin-walled, easily dilated at the site of* tion, and admits an unexpectedly large cannula ease This method has proved eminently satisfactory without any complication, and I recommend it to engaged in major surgery and not blessed with assistants

The only disadvantage has been that on nine the cephalic vein has been absent from its normal tion Such patients have had *small transverse* taneous veins across the front of the shoulder, and I not now explore for the cephalic vein when such veins present

Anatomy

The cephalic vein begins on the radial side of dorsum of the hand, runs up the radial side of the and at the bend of the elbow gives off a median branch medially to join the basilic vein Thereafter travels up the outer side of the arm lateral to the muscle until it crosses the anterior aspect of the of the deltoid muscle , it next approaches from lateral side the groove between the deltoid muscle the pectoralis major muscle, *and soon runs* in the itself (see figure) , about two inches higher the sinks deeply into the groove and becomes difficult to by ordinary dissection No artery accompanies it ever deepening course leads it to the fascia, which it pierces, and it ends in the vein The junction of tributary with recipient vein be guarded by valves, but these are often absent

This description is based *on surgical* exploration on several post-mortem dissections

Procedure

It has been found convenient to cannulate the when general anæsthesia has been induced and with patient supine The arm which will be uppermost operation is selected, because flexion and the *lowermost arm* has caused angulation of the and failure of the drip With the arm held away from side of the body at about 45° (most easily by placing the hand under the upper part of the an incision 2 inches long along the lower part of deltoideopectoral groove, and extending just below beginning of that groove, will expose the vein If vein is not in the groove it will be found slightly laterally, over the deltoid muscle The vein is thin easily dilated, and in an adult takes the largest Bailey cannula , the medium Bailey cannula and normal adult *Sutton cannula* can usually be into the vein of a child aged 5–10 years After I customarily insert a distal skin stitch which cannula in its second loop, and a proximal skin which, passing under the vein, is left long and until after the cannula has finally been removed

THROMBOCYTOPENIC PURPURA SSOCIATED WITH OXYTETRACYCLINE THERAPY

A G BECKETT
B.M Oxfd M R C.P
NIOR MEDICAL REGISTRAR, ROYAL FREE HOSPITAL, LONDON

A. W H. FOXELL
M.B Lond
EMATOLOGIST, NORTH WESTERN GROUP LABORATORY LONDON

ALTHOUGH oxytetracycline is known occasionally to use toxic reactions in the skin and gastro intestinal act, no case of blood dyscrasia (including thrombo topenic purpura) due to this drug has been reported in is country

In a nation wide survey of 1448 cases of blood dyscrasia the United States, Welch et al (1954) report 41 cases of blood orders associated with oxytetracycline therapy including cases of thrombocytopenia in 4 of which no other drug s given. The outcome and details of these cases are not ported. Of the 499 cases of thrombocytopenia 62 were ssified as due to 'infection' and 266 as idiopathic. It is refore possible that some or all of the cases associated with ytetracycline therapy should have been classified under ther of these headings.

We describe here a case of thrombocytopenic purpura ssibly due to oxytetracycline

Case-report

A man, aged 77 was admitted to hospital on Oct 19 1954 th bilateral pneumonia, which had started 10 days earlier th tiredness followed 3 days later by pain in the chest and termittent ache in the right ear For at least 10 years he had d Paget's disease of bone 8 years previously he was found have diabetes mellitus, which was subsequently treated by et alone. There was no history of any tendency to morrhage.

On admission his temperature was 99°F pulse rate 100 d respirations 28 per min. He was flushed and dyspnoeic th signs of consolidation at the left base and coarse crepita ons with expiratory rhonchi at the right base He had a llapsing pulse and blood pressure 160/70 mm. Hg Paget's sease of the tibiæ was present the changes being more onounced in the right leg There was no retinopathy the ee and ankle jerks were absent but vibration sense was esent.

vestigations

Radiography of the chest showed extensive pneumonic anges in the lower zones, greater on the right side On ct 20 the hæmoglobin was 90% (13·3 g per 100 ml) and the hite cells were 9000 per c.mm. (differential count of normal stribution); the erythrocyte-sedimentation rate (E.S.R.) as 120 mm. in 1 hour (Westergren) The serum alkaline osphatase level was 9·5 King Armstrong units per 100 ml he sputum contained scanty pus cells and on culture grew *reptococcus viridans* Cultures of swabs from ear and eye ere sterile

reatment and Progress

Treatment with penicillin and sulphadiazine started on the ening of admission by his private doctor was continued r 24 hours; but, as there was no improvement and his ndition was serious, these drugs were stopped and he was ven a course of oxytetracycline 1·0 g initially followed by 5 g. twice daily Little or no improvement followed at first cute otitis media was diagnosed on Oct 24 and was treated ith chloramphenicol in propylene glycol which was applied to e auditory meatus on a wool wick 6 hourly for 18 hours. yringotomy was then performed under general anæsthesia nd the discharge stopped a few days later

On Oct. 26 the patient had acute cardiac failure which proved after venesection and administration of oxygen and travenous aminophylline Subsequently he was treated ith digitalis and mersalyl and had no further episodes. ecause of the severity of the illness and this episode of rdiac failure the dosage of oxytetracycline was increased ·5 g 6 hourly being given for the next 6 days. This produced clinical improvement the symptoms decreasing and the temperature, which had been 99–100°F falling to normal The signs in the lungs did not change however and radiography showed increased shadows in both lower zones extending into the mid zone on the left

The white-cell count, which on Oct 27 was 21 000 per c.mm (neutrophils 91%) fell to 10 000 per c.mm. 9 days later The E.S.R. was now 65 mm. in the first hour The sputum again produced a heavy growth of *Strep viridans* Oxytetracycline was continued on a reduced dosage 1 g daily in two divided doses for 8 days, making a total of 26 g in 22 days.

Blood Dyscrasia

On the third day after stopping the oxytetracycline the patient had a severe epistaxis followed next day by more epistaxes and gross hæmaturia By this time he had developed extensive hæmorrhagic purpura During the next 24 hours many fresh cutaneous hæmorrhages appeared and the hæmaturia continued At this stage he had normochromic and normocytic anæmia thought to be due to blood loss The hæmoglobin was 66% (9·8 g per 100 ml) red cells were 3 270 000 per c.mm and white cells 18,000 per c.mm. (neutrophils 63%); his platelets had decreased to 15 000 per c.mm The bleeding time was much prolonged no evidence of cessation of bleeding occurring after 18 minutes. The prothrombin time and clotting time were normal and the Hess test was positive Next day there were further skin hæmorrhages and hæmaturia. The hæmoglobin was 62% (9·2 g per 100 ml) platelets were 11 000 per c.mm. and white cells 16 700 In the evening he started to cough up bloodstained fluid and vomited coffee grounds. His general condition deteriorated rapidly and in the early hours of Nov 17 he died

The Sternal Marrow

Sternal marrow puncture was done 15 minutes after death the differential marrow count being as follows: myeloblasts 1% promyelocytes 1% neutrophil myelocytes 8% metamyelocytes 8·5% neutrophil polymorphs 51%, eosinophil polymorphs 1%, early normoblasts 4% intermediate normoblasts 6% late normoblasts 14·5% plasma cells 0·5% lymphocytes 4% and monocytes 0·5% The myeloid/erythroid ratio was 2·9/1 There was no evidence of platelet production, and only an occasional promegakaryocyte was present. No other evidence of toxic changes was seen. The development of the myeloid and erythroid series was normal apart from some increase in mature polymorphs.

Necropsy

There were numerous petechiæ in the skin of the trunk and limbs, the pericardium and endocardium, and the mucosa of the stomach small intestine colon and urinary bladder Ecchymoses were present in the pelves of the kidneys and in the leptomeninges over the left frontal and parietal lobes of the brain The lungs showed organising fibrinous pleurisy and gangrenous pneumonia with abscesses up to 2 cm. in diameter in the lower lobe of the left lung An older unresolved pneumonia, with abscesses up to 1 cm in diameter in the lower lobe of the right lung and œdema and congestion of the remainder of the lungs were also found The spleen showed subacute septic changes. Pus was present in the right middle ear The neck and upper half of the shaft of the right femur and the sternum contained red marrow

Discussion

Thrombocytopenia is occasionally associated with septicæmia but throughout his illness our patient did not show any clinical evidence of this and it seems improbable that the purpura was due to septicæmia He had suppurative pneumonia diabetes mellitus and Paget's disease of the bone none of which are known to produce thrombocytopenia

Sulphonamides and chloramphenicol cause thrombocytopenia on rare occasions, but we do not think they were responsible for it in this case because the sulphadiazine was given for only 24 hours to a total of 2·5 g and the bleeding did not come on until 3 weeks later Chloramphenicol was applied aurally only on three occasions in 18 hours and this local application could scarcely have had a toxic effect on the marrow

In spite of the widespread use of mercurial diuretics we have found only 3 published reports of thrombocytopenia possibly due to mercurials (Butt and Simonsen

1950) Similarly, although iodides have been extensively used for a long time, there are very few instances of thrombocytopenia due to iodides Dennig (1933) reported 2 unproven cases, and Davis and Saunders (1946) described a proven case of purpura, due to potassium iodide, in which the platelet-count on one occasion was 100,000 per c mm We think it most improbable that either mersalyl or elixir of caffeine iodide, both of which were given for a short time only, caused the thrombocytopenia in our patient In addition he was treated with aminophylline, digitalis, and chloral, none of which is known to cause thrombocytopenia Aspirin, amidopyrine, ‘Sedormid,’ and other drugs producing thrombocytopenia were not known to have been given either in hospital or in the previous 2 months

It therefore seems likely that the oxytetracycline was responsible for the thrombocytopenia in the present case The almost complete absence of any members of the megakaryocyte series seems to indicate that the action of oxytetracycline was to produce directly or indirectly a selective marrow depression affecting only the precursors of the platelets The only other toxic manifestations were those due to mild gastro-intestinal irritation, a complication not infrequently associated with the use of oxytetracycline

Although our patient's pneumonia appeared to have been held in check by the intensive drug therapy, the final outcome of his illness was determined by the thrombocytopenia this might have been reversible in a person less seriously ill

Summary

A case of thrombocytopenia purpura in a man, aged 77, with suppurative pneumonia is described The bone marrow showed selective depression of platelet production

The thrombocytopenia was possibly caused by oxytetracycline

We wish to thank Dr Una Ledingham for her permission to publish this case

Preliminary Communication

PITUITARY-RADON IMPLANT FOR BREAST CANCER

CERTAIN tumours, at some stage of their progression towards autonomy, may depend on hormones produced by the endocrine glands of their hosts For example, total ablation of the suprarenal glands and ovaries, by removing the sources of œstrogenic steroids, has proved of benefit in some cases of advanced mammary cancer The pituitary gland has also been removed for the same purpose,[1] but this major operation carries a significant mortality, so a method has been evolved at the Western Infirmary, Glasgow, of destroying the pituitary gland by implanting radon seeds, thus obviating the necessity for open operation

Technique

The seeds are introduced through a cannula inserted into the pituitary fossa through the nose and the sphenoidal sinus To enable this to be done under radiological control, an adjustable director apparatus, incorporating radio opaque protractors in two planes, has been constructed After the nose has been swabbed with spirit and a solution of 1 1000 adrenaline, the patient's head is fixed in the apparatus (fig 1), and the cannula is inserted through the director tube into the nostril Radiographs are taken in anteroposterior and lateral planes, and the alignment of the cannula is corrected accordingly The cannula is next advanced as far as the roof of the nose, and further radiographs are taken to confirm the alignment and to measure the distance from the point of the cannula to the sella turcica The trocar is inserted and by firm pressure the cannula is bored this distance through the sphenoidal air sinus and the base of the sella turcica The point of the cannula now lies within the pituitary fossa, this position being confirmed

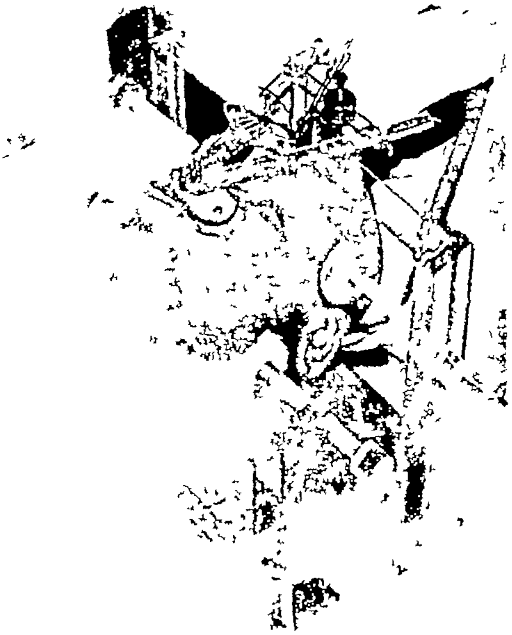

Fig 1—Head of patient fixed into apparatus and cannula into nostril

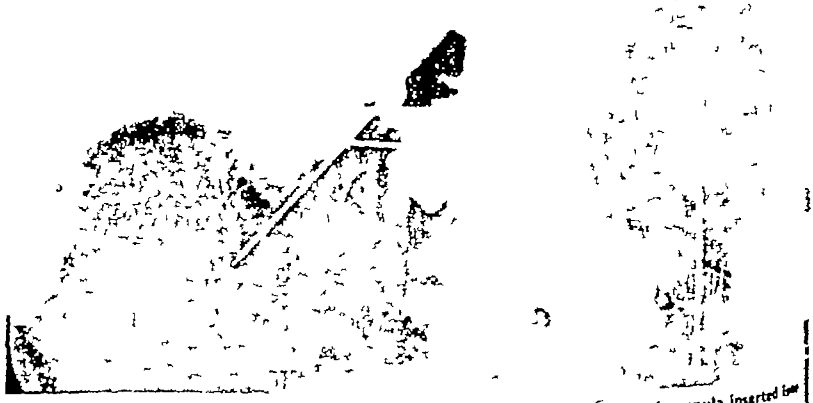

Fig 2—Anteroposterior and lateral radiographs of skull, showing trocar and cannula inserted in pituitary fossa.

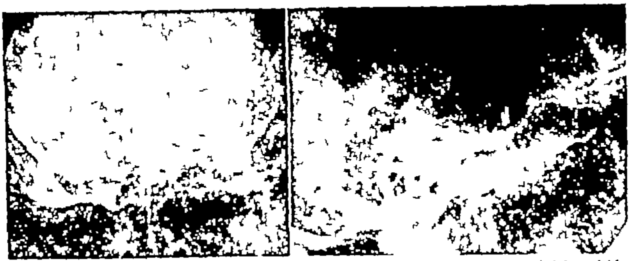

Fig 3—Anteroposterior and lateral radiographs of pituitary fossa showing two seeds lying within gland.

her radiographs (fig 2) Radon ds are introduced (fig 3) the rument is withdrawn and the al cavity is packed with gauze ked in adrenaline solution is pack is removed after twelve urs

Results

This operation is done under neral anæsthesia and antibiotic ver The dose of radon now ed is 15 mC in three seeds (in e earlier cases two seeds 10 mC re used) and maintenance rapy with cortisone (25 mg lly) is instituted Up to now ne cases of advanced cancer have en treated by this method without mortality or rbidity All the patients have complained of mild adache on the evening of the operation but in no stance has this persisted beyond the second post rative day In only one case was the convalescence mplicated by evidence of infection the patient's mperature suddenly rising three days after the implant his was rapidly controlled with aureomycin and no ganisms were isolated from the cerebrospinal fluid atients are ambulant the day after the implant, and are lowed home in six days

The progress of these patients is being followed nically radiologically and biochemically and the fect of the implant on certain endocrine functions being studied

The simplicity of this method allows its use in cases suitable for major surgery and we believe that it ay prove as effective as, but less hazardous than tal adrenalectomy and oöphorectomy Although so far this treatment has been used exclusively for advanced cancer it may prove applicable to pituitary hyperactivity

We wish to record our sincere gratitude to Prof C F W Illingworth for permission to treat these cases in his unit and for his encouragement in the development of this project to Dr A A. Charteris and his staff of the department of radiotherapeutics for their coöperation to Miss Ann Hendry superintendent radiographer Western Infirmary for her invaluable assistance with the radiographic technique and to Mr Angus MacDonald who constructed the director apparatus in the Western Infirmary Workshop

Endocrine Response to Trauma

THE section of surgery met on May 4 under the hairmanship of Mr HAROLD EDWARDS the president o discuss Endocrine Response to Trauma

Prof FRANCIS D MOORE (Boston Mass) said that the ndocrine glands were the motors which drove surgical onvalescence, and study of their behaviour was not an cademic exercise but essential for the practical direction f surgical care

In response to the stimuli of pain fear, blood loss and ether anæsthesia there appeared to be pronounced adrenomedullary secretion not yet extensively studied by biochemical methods After trauma the blood level of corticotrophin rose and the blood level of compound F increased to four or five times normal Within sixty seconds of trauma the blood-corticoid level in the adrenal vein increased to a hundred times normal In addition sodium conservation occurred presumably as aldosterone was secreted but the changes in sodium and chloride metabolism did not coincide with the movement of nitrogen and potassium In addition this early phase was marked by alterations in water metabolism which might be due to the effects of antidiuretic hormone

After these early changes there was a period which resembled the withdrawal of adrenocortical hormones and was reflected in a decreased urinary output of corticoids and nitrogen It occurred within a few days of abdominal operations but later after fractures. This often involved a drastic reduction in urinary total nitrogen excretion from 12–15 g daily to 5 g or less.

There then followed a third phase—that of spontaneous anabolism This was the period of rebuilding It started about one week after pneumonectomy or gastrectomy and lasted three to five weeks. A patient weighing 70 kg accumulated 3–7 g nitrogen per kg per day The glands mediating this phase were thought by some to be the gonads but Professor Moore believed that growth hormone was more probably involved This had not been proved Finally fat replacement took place, ceasing when the patient reached normal weight

If the operation was followed by complications, such as sepsis, pulmonary embolus or wound dehiscence the secretion of corticoids increased again, even though they might have fallen from the initial postoperative high level.

Ether anæsthesia given to volunteers increased the blood-corticoid level but thiopentone did not. Moderate hæmorrhage of 770 ml blood did not cause increased corticoid secretion Alterations in corticoid levels and depression of circulating eosinophils of the same order as he had observed in surgical cases could be brought about in a healthy volunteer by the intravenous infusion of 25 units of corticotrophin

Prof G M WILSON (Sheffield) spoke about the postoperative fall in plasma sodium and chloride levels. If patients who had undergone partial gastrectomy for peptic ulcer were kept on a restricted water intake the plasma sodium and chloride levels remained steady for twenty four hours and then declined The decrease was not attributable to postoperative water retention alone and it was not easily related to any known aspects of adrenocortical or pituitary function It had been shown that interference with the temperature or oxygen supply of tissue slices caused movement of sodium and chloride ion from the medium into the cells.

Professor Wilson went on to discuss changes after bilateral adrenalectomy and ovariectomy for carcinoma of the breast The eosinophil-count fell but when the patient was put on 100 mg cortisone daily after operation the eosinophils rose again distinctly The plasma sodium and chloride decreased The urinary excretion of 17-ketogenic steroids was normal, increasing slightly when cortisone support was given, it rose greatly after operation, while the urinary 17-ketosteroids fell He had found similar changes in a patient maintained on 150 mg cortisone a day, although the urinary 17 ketogenic-steroid excretion did not change much after operation In these patients, maintained on a constant dose of cortisone, the urinary conservation of sodium and chloride was good in the postoperative period, even in the absence of the adrenal cortex Professor Wilson cautioned against the over-enthusiastic use of sodium chloride infusions in the postoperative period

Mr F W HOLDSWORTH (Sheffield) emphasised the importance of œdema of the wound as a cause of fluid-loss in injured patients Fluid-loss into the wound began two to three hours after injury and continued for two to three days In wounds of moderate size it was well tolerated and did not call for replacement, but in very large wounds, such as burns, replacement was necessary Direct blood-loss must be replaced quantitatively, though assessment of the amount lost was difficult and the usual clinical criteria, such as pallor, tachycardia, and fall in blood-pressure, might be misleading since these might be due to neurogenic causes even where there was little or no wound The most reliable guides to the quantity of blood lost were the size and type of the wound considered with the systolic blood pressure Replacement should be quantitative, for there was considerable danger associated with over trans fusion The presence of lacerated tissue had a profound toxic effect, so traumatic wounds must be excised as soon as possible The dangers of anæsthesia had probably been greatly exaggerated, but he considered that the preoperative nutritional state was very important

Mr L P LE QUESNE pointed to the dangers of adopting postoperative changes in urinary salt excretion as a basis for therapy The changes usually reflected natural metabolic changes in the body

Dr STUART MASON illustrated the effect of total hypophysectomy on the salt and potassium balance while the patient was maintained on a constant dose of corticotrophin (60 mg daily) and constant salt intake Similar data, together with nitrogen, phosphorus, and calcium balances, illustrated the effect of total adrenalectomy in a patient maintained on a constant dose of cortisone (80 mg daily) In both patients the metabolic response to trauma was similar to that found after operation on patients with intact adrenals The results supported Ingle's concept of the "permissive" rôle of the adrenal

Prof C H GRAY pointed out that by existing chemical techniques only a very small number of the steroids secreted by the adrenal cortex were estimated Furthermore since the adrenal cortex secreted at least five different hormones with three different kinds of function it was possible that the anabolic and katabolic changes after trauma were due to the secretion by the adrenal of different proportions of these substances

Replying to the discussion Professor MOORE said that adrenalectomised dogs receiving cortisone had a raised blood-level of corticoids If they were then anæsthetised with ether the corticoid level rose further, and ether anæsthesia and trauma combined also led to an increase He wondered whether this was due to failure by the liver to inactivate corticoids

The nature of the wound was more important in determining the metabolic response than in determining the endocrine response The mechanism of this seemed to be extra-adrenal

Hypothermia in dogs or man caused the blood corticoid response to be abolished, warming was followed by a delayed response

Reviews of Books

Multiple Sclerosis

DOUGLAS MCALPINE, M D, F.R C P, physician-in department for nervous diseases, The Middlesex Ho NIGEL D COMPSTON, M.A, M D Camb, M R.C.P., physician, The Royal Free Hospital, London, Car LUMSDEN, M D Aberd, Sir Henry Head Research of the Royal Society Edinburgh and London E Livingstone 1955 Pp 304 35s

To produce a 300-page volume on a single dis not without hazards On the one hand it is questi whether the intrinsic interest of disseminated sc as we now know it is sufficient to compel the con attention of the expert On the other hand, the stu or the clinical dilettante is unlikely to devote a seem disproportionate amount of time to the contemp of clinical pleomorphism We therefore greet monograph by Dr McAlpine and his colleagues mixed feelings

It consists of a global account of the disease derived experience of over 1000 cases seen at the Middlesex Ho during some twenty two years The first and larger p the book deals with details of clinical history, geogr factors, accessory clinical findings, and the problem diagnosis, prognosis, and management It is readably clearly written, and it is undoubtedly of value to have mass of information collected into a single book with statistical evidence on prognosis and on variation in composition of the cerebrospinal fluid The section differential diagnosis should help the general physician, may, however, be surprised to find an essay on cer spondylosis included in this chapter The review of pre day management is practical While recognising the me of specific therapy, it shows how much can be achieved long-term management An unexpected enthusiasm intravenous neoarsphenamine and liquor arsenicalis possible minor blemish in this balanced report

The second part of the book is mainly on pathology, some interesting excursions into demyelination, to wh Dr Lumsden's experimental work has clearly contribute largely This section includes some excellent photogra The final chapter on ætiology, though it contains noth new, sets out clearly and concisely the present proble By these qualities it is characteristic of the wh volume

Crime Detection

Modern Methods of Criminal Investigation ARN SVENSSON, assistant, OTTO WENDEL, chief assista National Institute of Technical Police, Stockh Amsterdam and New York Elsevier Publishi Company London Cleaver Hume 1955 Pp 38s 6d

THE considerable success that attended the appeara in 1949 of the Swedish *Handbok I Brottsplats Unde sökning* fully justified its translation into English, a the two authors—technical and police experts at the National Institute of Technical Police in Stockholm have wisely broadened the scope of the text for inte national reading It has been so substantially revised and superbly illustrated from the authors' own crime fil as to constitute a new book in clear impeccable Engli and remarkably comprehensive within a comparativel small space, it is undoubtedly the best practical gu to crime investigation we have yet seen

The authors carefully avoid elaborating the mo difficult bench techniques—those of blood grouping, instance—that have by now been passed to experts in serology, but they do not fail to indicate where to loo for blood at a scene of crime, how to preserve the m material, and in what respects it may be tested Print hairs, fibres, dusts, glass, wood—all receive authorita treatment, and there is a remarkable piece of writing Svensson on firearms and explosives

In use the book is sound and really practical C I D office, no crime laboratory, and few unive departments of forensic medicine could fail to pro greatly by constant recourse to this short but comp

nsive guide to technical police methods It is a
ne tribute to the respected institute from which it
nnes.

ypertension and Nephritis

5th ed ARTHUR M. FISHBERG M D director of medicine Beth Israel Hospital New York. London Baillière Tindall & Cox. 1954. Pp 986 £5

"Fishberg" needs no introduction as an exhaustive nd valuable bibliography on hypertension and nephritis. n the fifteen years since the last edition progress in this ubject has been both deep and wide The main advances nclude clearance studies of renal function and extensive esearches on the relationship between the kidney and ypertension These on the one hand have led to new peculations on the genesis of renal hypertension and n the other hand have helped to clarify the classification f Bright's disease New light has been thrown on specific iseases of the kidney, especially diabetic glomerulo clerosis, chronic pyelonephritis, and tubular necrosis. pecific tubular disorders leading to electrolyte disturbnces have been discovered Dr Fishberg's summary of ecent work on these subjects, and his references, are an xcellent starting point for anyone requiring further nformation He still regards chronic lipoid nephrosis as n entity and gives inadequate weight to the recognition nd differentiation of type-1 and type-2 nephritis. In view of the numerous drugs now available for the reatment of hypertension, it is welcome to find a warning n this section that many individuals not only need no reatment, but are much better off without it'

An Atlas of Operations for Trauma

OTTO RUSSE Vienna and Bonn: Wilhelm Maudrich for Medizinische Wissenschaften. 1955 Pp 100 DM. 50

THIS Atlas, with its 48 full page plates, and text in German, French, and English, is elegantly got up; the translations are adequate and the pictures are clear But it is a pity that some of the operations so well depicted are culled from the world literature with no assessment of their feasibility or value The illustrations include methods of purely historic interest, such as the use of 'pinch grafts, and equal emphasis is placed on procedures that are established, questionable and even just imagined Oversimplification has led to attention being focused on bone injuries to the neglect of the associated soft tissues, in relation both to repair and to the surgical approach Thus the skin incisions shown are entirely orthodox and take no account of the need, at the acute stage of injury to preserve undamaged soft tissues. The methods of treatment required at the emergency stage are not distinguished from those of value at a later stage of reconstruction In resuscitation blood transfusion is mentioned on a par with subcutaneous saline To present so much in so small a space is necessarily very difficult and in this Atlas we feel, the diagrammatic approach has unfortunately made the surgery of trauma seem more a matter of skilful carpentry than of applied biology

Biochemistry of the Aminosugars

P W KENT M.A B.SC., PH D., D.PHIL. F.R.I.C; M W WHITEHOUSE B.A. B.SC A.R.I.C department of biochemistry University of Oxford London Butterworths Scientific Publications. 1955 Pp 311 40s

To those who think of plants and animals in terms of proteins, fats, and carbohydrates, the presence in the body of sugars containing amino groups may come as a distinct surprise They are as it were neither fish, fowl nor good red herring yet they are present in the skeleton, in mucins in the substances responsible for the blood-groups in the serum globulins in antigens, in antibiotics, and in chitin—in short in almost every walk of life They may appear as monosaccharides or polysaccharides and they may combine with proteins and lipoids in the most variable proportions They owe their construction form and function during life to a series of enzyme systems which maintain them in their steady state by a process of active metabolism. This book is the first comprehensive attempt to describe them since Levene's classical monograph in 1925.

The first part covers the biological associations of the amino sugars their metabolism, enzymic degradation their rôle in chondroitin heparin and chitin, and their share in the construction of the various mucins. There is a chapter on bacterial and fungal products which, as might be expected, are widespread and important To those who have been the victims of a severe pyrogenic reaction it may be of some interest if not perhaps comfort to know that their misery was due to an amino polysaccharide

The second part of the book deals more specifically with the chemistry of these amino components. It describes how they may be detected and isolated and goes into their structure, synthesis and reactions so far as they are known at present Glucosamine receives the most extensive consideration but galactosamine has a chapter to itself and another chapter is devoted to the hexoses with two amino groups. The fructose mannose xylose arabinose and inositol compounds are left to the concluding chapters. A considerable number of references are given after each chapter and there is a short postscript at the end of the book to bring the literature up to date at the time of going to press

The authors are to be congratulated on having produced a book that is both interesting and a notable work of reference.

The Digital Circulation

MILTON MENDLOWITZ, M.D F.A C P, associate attending physician, Mount Sinai Hospital, New York. New York Grune & Stratton. 1954 Pp 182 $6 75

IN this short monograph Dr Mendlowitz surveys the remarkably complicated subject of the digital circulation in health and disease, to which he himself has devoted much effort. Clubbing a teasing subject which has greatly attracted him, is as well discussed in a single chapter as it could be The theory of its ætiology, "an attempt to point the way is at least as reasonable as any other, though even Mendlowitz finds some difficulty in explaining the clubbing that accompanies intestinal disease and cirrhosis. A comprehensive list of references, numbering over 600 gives just credit to the pioneers in the study of the subject.

Retropubic Prostatectomy

For Benign Enlargement of the Prostate Gland. FRANCIS A BENEVENTI M.D F.A C.S., attending urologist, Oswald Swinney Lowsley Foundation St Clare's Hospital New York Springfield Ill.: Charles C Thomas Oxford Blackwell Scientific Publications. 1954 Pp. 227 60s

ALMOST ten years have elapsed since Millin introduced his retropubic approach to the surgery of prostatic obstruction but despite the wide adoption of the technique in the British Isles and Europe, American urologists have largely remained faithful to the transurethral methods. Dr Beneventi of New York, has given us the first transatlantic book on the subject, a beautifully produced work with many outstanding drawings by Mr W Didusch.

The anatomy of the prostate and surrounding structures is capably dealt with, though some of the photographs might have been omitted without much loss. The chapters on preoperative and postoperative management are thoroughly good and do not advocate unnecessary investigations Not everyone however will agree with the author's practice of 15 minute bladder irrigations in the early postoperative period The technique of the operation for enucleation of simple adenomata differs little from that employed in Britain though many will cavil at some pronouncements based apparently on a relatively small experience of 100 cases. It is difficult for example to accept that retropubic prostatectomy for the small gland is not feasible as the dense lateral plexuses of veins leave little room for exposure or that a bladder neck which will admit the tip of the middle finger following enucleation requires no plastic enlargement No mention is made in this connection of the hypertrophied trigone Dr Beneventi admits that he makes no attempt to secure a watertight closure of the prostatic capsule and accordingly leaves the urethral catheter (a modified Foley type) in for 6–7 days; his high incidence of meatal stricture (7%) may possibly be related to this practice Some 23 pages are devoted to osteitis pubis but the author concludes that the incidence of this complication is no greater after the retropubic operation than after operation by other method No mention is made of the occasional involvement of the vertebral bodies

Despite such minor criticisms the work will undoubtedly appeal to urological surgeons

Geisteskraft und Geistesstörung im Alter

Ärztliche Betrachtungen zum Altersproblem A KIELHOLZ, W A STOLL A L VISCHER, H WALTHER BÜEL, J WYRSCH Zürich Art Institut Orell Füssli Ag 1954 Pp 45 Fr 3 60

THIS collection of essays from Switzerland on psychiatric problems of old age is of some interest for the glimpses *it provides of work in this field on the Continent*

Most of the contributors make the descriptions of Kraepelin *and Bleuler the starting* point of their analysis of mental illness in old age, but these are inadequate when approaching the social and psychological problem of ageing with which contemporary psychiatry is faced To fill the gap some *authors go to Selye for* inspiration, others to Shakespeare's *King Lear* and the portraits of Rembrandt The essays however, reflect an approach to the psychological problems universal among old people in urban communities that is more practical and in keeping with human dignity than the formulations of some schools of psychopathology The style is rambling, and many of the sentences are of breath bereaving length, and some may feel that the effort required of the *reader is* disproportionate to the number of useful statements

New Inventions

PILOT TUBE FOR BLOOD BOTTLE

OPINION is still sharply divided as to whether a pilot tube is a safe and reliable accessory to a bottle of blood Some object to it on the grounds that, since it is not an integral part of the pint bottle, some change-over may occur, either at the donor session or later, whilst others consider that the bottle must in any case be sampled so that a stained smear may be examined to exclude the presence of bacteria

However valid these objections may be, there is no doubt that the risk of infecting the bottle at the time of sampling is a serious one Even though the most careful and aseptic technique is used (perhaps questionable when carried out by junior staff at night or in emergency), the blood must be transfused within twenty-four hours or not at all This advice, given by the Ministry of Health in "Notes on Transfusion," if rigidly adopted, must impose a strain on the blood-bank. It is often necessary to have several pints standing by for a patient for two or three days, and it is also not always easy to switch any unrequired cross-matched blood to another case within twenty-four hours

Examples of transfusion reactions known to be due to infected blood are happily rare, and although the routine preparation of a stained smear from the bottle is excellent in theory it is not always practicable If this additional test is considered necessary, the best time to do it seems to be immediately before the transfusion is set up, cross-matching having been done some time previously with the aid of a pilot tube

It is to overcome these objections to the pilot tube that the following design, method of attachment, and filling procedure, have been extensively tried and now adopted in the area served by the Sheffield Regional Transfusion Centre The tube, of 4 ml capacity, is more like a small bottle because it has a neck with a screw thread and is closed by a metal cap, having a central hole under which lies a rubber bung (fig 1) The base is rounded to give strength and, it is hoped, to act as an additional deterrent to removal, since the bottle will not stand on a flat surface

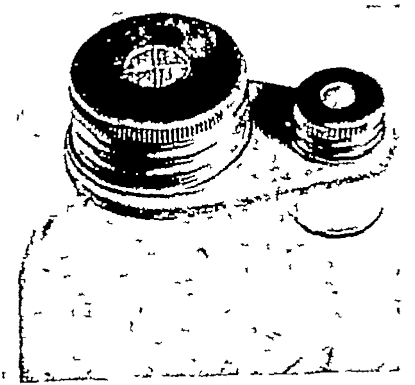

Fig 1

The attachment consists of an aluminium strip flanged *round the edge to give greater rigidity and* perforated by two holes The diameters of these are such as to allow the strip to pass over the screw threads of both bottles but no further Both the bottles are firmly united when *the caps are screwed home, and* no accident or careless handling can separate them A label is therefore considered superfluous, for, even if the smaller cap is removed, which is contrary to instructions, the shoulder *of the large bottle prevents the* pilot bottle from slipping through

Fig 2 illustrates the method of filling the pilot bottle at the donor session in three stages, A, B, and C, the whole process being completed immediately after venesection and before the pint bottle joins those from other donors The lengths of tubing in the taking sets shown have been shortened for the sake of clarity A is a unit ready for use, with the donor's *needle protected* by a shield until the moment of venepuncture. The vial attached by an elastic band is retained, when filled, at the transfusion centre for grouping and Kahn testing

B shows the unit after venesection The *tubing* is clamped, and the needle is withdrawn from the arm and inserted into the vial, which now carries a label with a serial number corresponding to that on the large bottle C shows the needle X *transferred to the* pilot bottle, which fills easily, after the clamp is released, having been vacuumised before sterilisation

The simplicity of this final movement, and the close attachment of the small bottle, *effectively* prevent the possibility of error or confusion

The pilot tube is manufactured by the International Bottle Company, 140, Park Lane, London, W 1, and the aluminium attachment by the Wolf Safety Lamp Co (William Maurice Ltd), Saxon Road Works, Sheffield, 8

Abuse of Antibiotics

LAST October 172 speakers contributed to the second Annual Symposium on Antibiotics[1] In opening the discussion, Dr HENRY WELCH not unreasonably said that it would take too much time o list the infectious diseases now partly or completely controlled by chemotherapy, instead he remarked that few of his large audience would not have some friend or relative who had been made well, or even been saved from death, through the use of antibiotic drugs There was much to justify President EISENHOWER's message to the symposium in which he described the meeting as an occasion for honouring all who through their work on antibiotics had made profound changes in the practice of medicine Those honoured would rightly include not only medical and scientific investigators, but also the drug firms whose energy and enterprise made possible the necessary research and development on a vast scale

With all this we are already familiar But, owing largely to our own folly the picture has a less favourable aspect VON OETTINGEN,[2] reviewing the untoward effects of the indiscriminate use of antibiotics, noted the possibility of such well authenticated complications as glossitis and stomatitis, nausea, vomiting, and diarrhœa anal pruritis, vestibular and auditory disturbances, aplastic anæmia, and allergic reactions of many kinds, including fatal anaphylactoid reactions serum-sickness, and skin rashes Admittedly most of these reactions are relatively uncommon in proportion to the widespread use of antibiotics, and most are temporary but enough of them may produce serious damage and even fatal results to justify an earnest plea for caution against uncritical use of antibiotics Apart from the danger to the patient such indiscriminate use must accelerate the emergence of resistant strains of bacteria among species which produce such forms This has been said many times in these columns and elsewhere, indeed it has been emphasised so often that its rehearsal may fall on deaf ears It may have been some such thought that led HUSSAR[3] to propose a more active measure—a crusade for the rational use of antibiotics In his own analysis of fatal antibiotic reactions he showed that about half of the patients had died from unnecessary medication. He estimated that about 25% of patients in the medical wards of general hospitals would probably benefit from antibiotics This figure was very close to that observed in three hospitals where strict indications had been set up for the administration of antibiotics But in three other hospitals the proportions of general medical patients treated with antibiotics were 32%, 38% and 41%, and in HUSSAR's view these higher figures reflect a too liberal use of antibiotics He proposed (1) a press release from the symposium condemning the irrational use of antibiotics, (2) systematic education of students and doctors on how to use antibiotics, (3) education to persuade the lay public that antibiotics are not invariably required, and (4) organisation of a National Registry of Fatal Antibiotic Reactions to reveal the true incidence of such accidents

What errors of judgment and practice have given rise to these sobering pronouncements? Three seem to deserve prominence First, there is a belief that antibiotics are non toxic and will do no harm even if they do no good It is easy to see how this view arose Penicillin our first antibiotic, had a much greater margin between effective and toxic dose than any previous antibacterial drug and untoward reactions were virtually unknown in the early days when it was administered in doses of the order of 15 000 units every four hours Only when very much larger doses came to be used—at first for special cases but later almost as a matter of routine—and when sensitised patients came for second courses of treatment did it become clear that the drug was not altogether harmless Later antibiotics are in general more toxic than penicillin and so allow less latitude in dosage The second defect in our thinking touches this very point Many doctors are guided by the popular but fallacious generalisation that if a little does good a lot will do better Many considerations doubtless combined to foster the use of big doses they were required for bacterial endocarditis, they were *bactericidal*, they would stop the emergence of resistant strains, they would make for less frequent administration, and they would penetrate to the deepest parts of hidden lesions Such considerations neglect two essential points that many antibiotics have a relatively narrow zone of optimal concentration,[4] and that the doses recommended by manufacturers are the outcome of extensive pharmacological and clinical studies As MENNIE[5] has rightly declared clinical investigators should aim at determining the smallest amount that is effective therapeutically One may smile at the plea for chairs of antibiotic medicine voiced by more than one speaker at the symposium but the surest way to encourage such projects is to give antibiotics so heedlessly as to create the impression that yet another specialty is required

The third wrong idea—inside as well as outside hospitals—is that since antibiotics are so dramatically effective against grave illnesses they will be at least equally useful for the treatment of minor disabilities But many conditions with an infective component—for example some skin diseases and chronic disorders of the cardiorespiratory systems—cannot be regarded as wholly or even mainly caused by infective agents On the whole antibiotics are disappointing in the treatment of such states, and the most probable outcome of their use is sensitisation of the patient, who disseminates resistant staphylococci For much the same reasons the so called prophylactic use of antibiotics is very often unwarranted It will be a bad thing if it comes to be regarded as a token of eccentricity or of over-confidence to do a deliberate surgical operation without "antibiotic cover" COURT and his colleagues[6] emphasise the crucial fact that the more frequently the staphylococci in a particular community are exposed to a particular antibiotic, the more likely they are to become resistant to it They reversed their earlier policy of treating with penicillin all staphylococcal infections in the newborn, and have had no cause to regret their decision no serious infection, such as pneumonia or osteitis, developed in any of the 633 babies with a superficial infection who were treated on conservative lines which precluded the use of antibiotics in the absence of some good clinical indication, such as evidence of a systemic infection They have kept erythromycin in reserve for the patient whose life may depend on it Dr FORFAR and his colleagues, whose letter appears on p 1071, use antibiotics somewhat more liberally but no less rationally How many others who prescribe antibiotics would care to defend their practice ?

Disseminated Sclerosis

SINCE the late war there has been gratifying progress in our knowledge of disseminated sclerosis This is due largely to the efforts of laboratory workers, but, as Dr MCALPINE shows in his Florence Tong lecture published in this issue, clinicians and field-workers have contributed much and may contribute much more In this disease with its protean symptoms, lengthy and varied course, and lesions that may be closely mimicked by other disorders, confusion in diagnosis is inevitable For this reason many early surveys of incidence have to be discounted, and there is now a need, as MCALPINE shows, for more accurate statistics in this and other countries

The high prevalence-rates in Northern Ireland[7] and northern Scotland, particularly the Shetland Islands, give much food for thought KURLAND et al[8] believe that prevalence is determined by geography rather than by race, the disease apparently being relatively rare in tropical countries it is, for instance, six times less common in New Orleans than in Winnipeg The Winnipeg rate is essentially the same as that for Boston, and is not much in excess of that for Denver, but both Boston and Denver have mean January temperatures considerably higher than that of Winnipeg As KURLAND and his colleagues remark, the prevalence-rate seems to increase rapidly as the winter temperatures drop, but after the "cold" weather areas are reached still lower temperatures cause no appreciable increase Once the disease is established temperature seems to have little effect on its course, for the life expectancy of patients is about the same in Winnipeg as in New Orleans SWANK et al[9] chose for their investigation rural Norway, because of its many isolated communities who for their food depend largely on their own resources They found a much higher incidence in the upland farming and dairying areas than along the coastal belt where fishing is the principal industry In the relatively prosperous farming districts they noted that the diet was richer in fat, particularly milk and animal fat, but they remarked that this greater consumption of fat might coincide with other factors having the same distribution In their studies they made use of true incidence figures as reported to them by neurologists and hospitals, for prevalence figures, being influenced by the duration of the disease, may not always indicate true differences in incidence Support for the view that an excessive intake of fat may be a factor in ætiology has not been forthcoming A priori, the quest for a dietary deficiency or for a cytotoxic contaminant might be expected to prove more profitable than investigating the effects of a surfeit of any foodstuff DE MORSIER and CHESNI[10] have described seven siblings, three of whom were employed as painters one died of tuberculosis, and in the other two disseminated sclerosis developed at the age of forty-two SHIELD,[11] noting a high incidence of disseminated sclerosis in those parts of the world where the land is intensively cultivated, has questioned whether inorganic fertilisers remedy acquired deficiencies in the soil The possible far-reaching effects of the "sophistication" of foods, and especially of dietetic insufficiency in early life, have been discussed by PLATT,[12] who calls for an investigation into the composition of the cerebrosides of myelin in the infant's nervous system, with special reference to changes in their composition as a result of substituting cow's milk (which is relatively deficient in lactose, and therefore in galactose) for human milk If, he asks, glycocerebrosides are substituted for the normal galactocerebrosides, do they persist into adult life, and if so are they more readily hydrolysed than the galactocerebrosides ? There is, as yet, no evidence that galactose is synthesised elsewhere than in the breast On the other hand, it is believed that throughout life there is a constant turnover of myelin and that the oligodendrocytes are probably concerned in this maintenance work An environmental factor such as this might not easily be reconciled with the rarity of the disease in each of monozygotic twins[13] but it would offer an alternative to the genetic explanation for familial cases PRATT, COMPSTON, and MCALPINE[14] report a family history in 6 5% of cases, and believe that this constitutes some support for the view that a genetic factor is at work According to KURLAND and his associates, however, the magnitude of the discordance in monozygotic twins rules out a simple genetic factor

MCALPINE, COMPSTON, and LUMSDEN,[15] in drawing attention to the hypothesis of oligodendroglial lysis, suggest that the objective should be not so much to determine the cause of the demyelination as to ascertain why there has been interference with the normal process of myelin resynthesis, but if in the sease there is an inherent failure on the part of the godendrocytes to resynthesise myelin, this still does t explain the focal distribution of the lesions, and he slowly expanding areas of demyelination multiple d often confluent, which apparently spread from nules The special vulnerability of the optic athways in disseminated sclerosis[16] and in the osely related condition of neuromyelitis optica has so to be explained It is evident, therefore that ttention must continue to be directed to a search for yelinolytic and probably oligodendrolytic agents as ell as to the blood vessels whose rôle remains obscure istological studies of the venules have been relatively rewarding and more precise methods for investi ating the vascular dysfunction in the nervous stem are needed. Fog et al[17] adduce evidence to how that the blood platelets are decreased during the tive phases of disseminated sclerosis, rising again, as n infections, during recovery They attribute the ll to an increased consumption of platelets during he active phase and suggest that this is part of a eneral reaction to the disease process. NATHANSON nd SAVITSKY[18] found that platelet adhesiveness is ncreased during periods of activity Other evidence ointing to a general reaction has been reported by ERNSOHN and COCHRANE[19] and VOLK et al.[20] VOLK t al have found an increase in the α_2 and β globulin believed to be the main lipid containing fractions of he plasma) in over three quarters of the cases they tudied, but since these findings were especially ommon in cases of long standing they deduce that he protein changes in the cerebrospinal fluid—commonly consisting in increase of the γ globulin—antedate the changes in the serum The early increase in γ globulin in the cerebrospinal fluid is believed to mply the establishment of an acquired immunity mechanism In this connection the premonitory symptoms, especially when these include a disturbance of general health deserve further careful study, as do also the transitory and sometimes almost momentary symptoms of some patients whether these are due o vasospasm, as FRANKLIN and BRICKNER[21] postulate, or increased vulnerability of the axis cylinders to chemical influences as MCALPINE suggests or even by both is undecided Study of the evolution of the symptoms may help not only to locate the lesions but also to assess their rate of progress MCALPINE[22] has shown that the mode of spread of paræsthesiæ is often in keeping with our ideas of focal diffusion

Better Nutrition

ONE of the most useful of the expert committees serving the World Health Organisation is the one jointly established with the Food and Agriculture Organisation to keep nutritional problems under review At its recent meeting the Executive Board of W.H.O. paid tribute to the excellence of the report of the committee's session last October,[1] when Prof B S PLATT presided and Dr NORMAN WRIGHT represented the Ministry of Food This report, it was felt, happily illustrated coöperation both between F.A.O. and W.H.O. and among national authorities

It is satisfactory to find protein requirements getting further close attention, for, though protein malnutrition is now recognised as a serious cause of ill health among women and children in most tropical and subtropical countries the amount of protein necessary for good health in various circumstances is still a matter on which opinions differ and evidence is insufficient Further investigation is needed too, on the development of protein rich foods for the supplementary feeding of breast-fed infants and for weaned infants in parts of the world where at present human milk is the only suitable form of protein the child can get Besides additions to diets, there is also the question of additions to foods, and the report considers, for example, proposals to add vitamin A to dried skim milk and to add potassium iodate (which is less liable to loss than the iodide) to the salt consumed by the inhabitants of goitrous areas[2] Equally important in their own way may be those additions to food which are made for the benefit not of the consumer but of the seller, and a section entitled 'Additives to Foods" is primarily concerned with such intentionally added non nutritive substances. The point made is not that any of the substances discussed are known to be harmful to human beings, but that a large proportion of them are not known to be safe Evidently opinions differ widely about many of the additives in common use for the report says that while twenty two countries permit the addition of certain specific colours in foods only 1 out of 82 such colours is permitted in all twenty two countries Furthermore it would be wrong to suppose that the only countries affected by these practices are those where technology is highly developed and where the consumer demands highly attractive foods, uniform quality, and a wide choice at all seasons addition of preservatives, for example, may be an important matter for countries which are economically and technically less developed but are situated in tropical or subtropical regions where food preservation entails special difficulties When foods enter as commodities into international trade it is particularly desirable in the committee's view that there should be international pooling of knowledge

Probably most of the accessory food factors essential in human nutrition have now been identified, but, though beri beri and scurvy have been degraded from major menaces to preventable nuisances, it has become plain that there are many foods with properties besides the absence of vitamins which are capable of contributing to ill health Opinion on the causes of pellagra, which formerly favoured a toxin in maize, shifted to nicotinic acid deficiency, but has now reverted to the idea that even if maize contains no specific toxin it has at least some positive dietary disadvantage when ingested in very large amounts The expert committee did not perhaps pay quite enough attention to the relation—in areas where a great deal of maize is eaten—between different maize-processing methods and the prevalence of pellagra The absence of pellagra from Mexico, where maize is prepared as *tortillas*, was mentioned, but nothing was said about the fact that it is also absent from areas of Africa which subsist mainly on maize prepared according to traditional methods, and that in many areas it has appeared since the introduction of dry-milling machinery Experiments at Cambridge and Reading which have lately been recorded in our columns[3] lend strong support to the opinion that a great deal depends on the method of preparation

[1] Joint F.A.O./W.H.O. Expert Committee on Nutrition: Fourth Report W.H.O./Nut/55 Nov 15 1954; Tech. Rep. Wld Hlth Org (in the press)
[2] See Scrimshaw N S, Cabezas A, Castillo F, Mendez J Lancet 1953 ii 166

In the past it has sometimes been assumed that nutritional problems will be solved by education, that feeding will automatically become adequate if instructions are followed implicitly It remains true, of course, that education is one of the most instruments of nutritional work, but it is also one of the hardest to use properly Difficulties arise not so much over the methods of teaching as over the content of what is taught The practical steps people can take to improve the level of their nutrition differ enormously from one region to another, and if the public fail to obey when exhorted to adopt changes which have proved beneficial elsewhere, but are quite impracticable in their own area, it is not they but their instructors who are at fault The W H O/F A O report emphasises the need for doctors and nurses to be told more about nutrition in their training, and certainly many of them work in circumstances where a good general knowledge of the subject is almost a first essential But it is vital to ensure that the instruction they will give relates to the actual dietary habits of the country in which it is to be applied, and not simply to those of the countries which produce most of the textbooks

Annotations

MARFAN'S SYNDROME

THE condition originally described by Marfan[1] as dolichostenomelia was apparently a congenital abnormality of the skeleton characterised by the length and slender proportions of the long bones The alternative title of arachnodactyly was introduced by Achard[2] to emphasise the "spider-like" appearance of the hands The syndrome is now taken to include various ocular abnormalities, of which subluxation of the lens is the commonest, and cardiovascular lesions, of which aortic dilatation and dissecting aneurysm are probably the most usual and are certainly the most serious

Achard first drew attention to a hereditary and familial tendency, but according to Rados[3] the family history was positive in less than 40% of cases McKusick[4] has now re emphasised the importance of heredity in the genesis of the syndrome An inquiry into the kinships of 50 unequivocal cases revealed a total of 105 affected persons, excluding many doubtful cases Of the relatives of all the available patients with subluxation of the lens, 70% had recognisable stigmata of the syndrome The genetic data indicate that the disease arises as a result of a single mutant gene which is subsequently transmitted as a dominant McKusick concludes that about 15% of all cases arise from such a mutation and 85% by transmission

The large number of tissues and structures that may be affected in Marfan's syndrome suggests that if a single defect is responsible this must be fundamentally important Its nature is by no means clear, from the microscopic appearance of cystic medial necrosis, which is the usual finding where the aorta is dilated or has undergone aneurysmal dissection, McKusick concludes that the elastica is probably the tissue primarily affected But it is difficult to see how such involvement can be responsible for the various ocular and skeletal abnormalities "unless one assumes that the presence of this defect during embryogenesis produces an abnormal setting in which these particular anomalies occur with increased incidence"[4] In any event the fundamental defect is functional rather than structural, at least in so far as it affects the aorta What is inherited is apparently an inability of the elastic tissues to withstand the normal wear and tear of life Consequently the patient may in childhood show no evidence of cardiovascular abnormality, but in adult life have severe aortic dilatation, valvular incompetence, and myocardial hypertrophy[4]

The presence of an underlying biochemical defect is strongly suggested by the production in rats fed on the seeds of *Lathyrus odoratus* of a syndrome that includes skeletal defects and degeneration of the media of the aorta leading to dissecting aneurysm[5] An active principle recently extracted from the seeds of *L odoratus* is β amino propionitrile Lathyrism in rats cannot justifiably be regarded as a phenocopy of Marfan's syndrome But the striking similarity of many of the features of these two conditions does support the view that the complex anomalies that make up the syndrome in man are based on a single transmissible biochemical defect

DOCTOR, NURSE, AND HOSPITAL

SOME twenty five years ago Dr G O Barber, who had then been two years qualified, saw a district nurse for the first time—as a pair of black stockings emerging from a low gipsy tent He had heard of her for the first time about ten minutes before, when she had telephoned to him to come and help with a difficult confinement She crawled out of the tent, and he crawled in, and in due course the baby was born In recounting this incident at a conference on the link between hospital, general practitioner, and the district nursing service, arranged by the Queen's Institute of District Nursing and held in London on May 12, he said how astonishing it was—and still is—that a medical student can complete his training and go into general practice without hearing a single mention of one of the most important members of his team His own efforts to remedy this defect are well known[7] he was the first to suggest and help to put into action the plan, now flourishing in several medical schools, of sending medical students to spend a week, during their last year of training, in the household of a general practitioner There they learn something of the work he does, and the people who help him to do it Otherwise, as Dr Barber pointed out, they get no chance, in the course of their training, of learning bout the long lives of patients before and after they me into the wards "They learn only the little chunk f illness that the patient has in hospital" In his own artnership the link of the doctors with all six of the urses in their district is strong: he and his partners ieet all of them at least once a week—either over a case, r over the telephone or when a nurse calls into the urgery, or a doctor calls in on a nurse to discuss a case r exchange information The nurses not only know iore about the social background of the patients than nybody else: they also know all their doctors but he dmitted that this is managed more easily in the country here doctors are relatively few than in the owns where a nurse may need to get to know 60-70 loctors

In comparison with the strong link of the general ractitioner with the district nurses his link with the ospitals is often weak and sometimes non-existent. Miss R Bonsey, deputy head almoner at St Thomas's Hospital suggested that it might be strengthened through her own department The district nurse should keep in ouch with the almoner and seek her help in the aftercare of patients especially if the illness has caused financial difficulties It is natural she said when a patient's physical state deteriorates for his doctor to seek the help of the hospital: it should be equally natural, when his social state deteriorates to seek the help of the almoner Miss D M Williams superintendent of the District Nurse's Home at Plymouth had some excellent recipes for keeping doctor district nurse, and hospital aware of each other, the basic ingredient being intelligent explanation, and the prevailing flavour her own fresh and friendly wit. After eighteen years in one place she does know at any rate as voices on the telephone the general practitioners—all 75 of them—with whom her nurses have to work. Nowadays, she said the district nurse does for the doctor many things he used to do himself—such as giving injections to diabetics She can help him best if he knows how her work is arranged and part of a nursing superintendent's job is to explain this to him The Plymouth doctors, she admitted with modest satisfaction now know that if they want a nurse to visit someone in the morning they must telephone before 8.30 A.M. and if they want her to visit in the evening they must telephone before 4 30 P.M. while if they wish to talk about a patient they know they can catch the nurse who attended him between 2 and 4 P.M. The nurses for their part carry with them lists showing the surgery hours of all doctors their telephone numbers and their half-days off, so that they can easily consult a patient's doctor when necessary The result of this collaboration is that a nurse (or a doctor) usually comes into the patient's room saying "Doctor (or nurse) has told me all about you"—a reassuring opening letting the patient know that he is in the care of a team Like Dr Barber she has found it more difficult to establish links with the hospital: but the same principles are applied there She explains the nurse's work to the hospital and she interprets instructions from the hospital in such a way that a discharged patient gets continuity of care from the moment he reaches home These are not always easy things to do as some of her examples showed

Thus it is now customary for district nurses to prepare patients for barium meal examinations At one time such patients were expected to report at the radiological department at 10 A.M. after preparation. Miss Williams explained to the department that it is not possible for the nurse to complete the preparation by this time she always has to begin her day by giving her diabetic patients their injections The department now arranges for barium meal patients to attend at 11.30 A.M. Another difficulty arises when a patient needing very large dressings is discharged in the evening or on a Saturday night when it is difficult for the doctor to prescribe what dressings are needed in time for them to be collected before the chemists close—perhaps for the weekend This, too was explained to the hospital and patients needing large dressings are now discharged with a quantity in a Cellophane packing sufficient to tide them over until more can be prescribed

Patients leaving hospital nowadays need far more nursing than they used to do and hence are much more likely to become alarmed if there is any break in care If they are on some drug such as digitalis, an interruption in treatment may be harmful Diabetics are taught in the ward to give themselves insulin, but when they get home everything looks different they lose their nerve, and there may be hours of delay before they get in touch with the district nurse She suggested that *before* any patient is discharged his doctor should be telephoned so that necessary drugs or dressings can be procured the district nurse can be asked to call, and his care can continue without a break from the moment he leaves hospital

The conference demonstrated again the truism that the National Health Service runs not on rules but on people—people willing to take trouble, get in touch explain and understand Such willingness is displayed by and large throughout the country by most district nurses and many general practitioners but not as yet very freely by hospitals Any member of the team, by keeping aloof can hamper the work of the others and unfortunately the brunt falls on the person least fit to take it.

PULMONARY TUBERCULOUS LESIONS

INTEREST in the pathology of pulmonary tuberculosis has been strongly reawakened by the introduction of chemotherapeutic agents which modify the course of the disease and have extended the use of surgery One of the most industrious workers in this field Dr E M. Medlar, of New York has collected his principal findings over the past twenty five years[1]

Before concentrating on experimental tuberculosis and thereafter on the pathology of pulmonary lesions Medlar had already shown himself capable of painstaking work on a very large scale By examining 100 000 *serial sections of* kidneys from 30 cases of pulmonary tuberculosis with caseation[2] he showed that tuberculosis of the kidneys could heal (in 5 of the cases there were healed scars only) and that renal tuberculosis could exist without organisms appearing in the urine and he concluded that "excretory bacilluria" was *invariably* associated with ulcerative tuberculous lesions in the kidney In this work he laid the *foundation* of our knowledge that fundamentally renal tuberculosis is bilateral though it is not always clinically so

Medlar now summarises earlier work which has contributed to the acceptance of new ideas about pulmonary tuberculosis In careful post mortem examinations of 1332 cases of sudden and unexpected death he found evidence of tuberculosis in 1000 though in 785 the lesions were too small to be clinically or radiographically recognisable He found that six-sevenths of the primary complexes were completely calcified Medlar remarks that multiple minute initial lesions in the lower portions of pulmonary lobes seldom give rise to progressive disease but such lesions must be examined to get a complete picture of the disease Only one eighth of these minute healed initial lesions were in the so-called "vulnerable portions" (the apical and posterior parts of the posterior segments of the upper lobes and the superior segments of the lower and right middle lobes) whereas in 96 cases with *minimal* (but probably clinically recognisable) *progressive disease* the great majority of the lesions were in the vulnerable portions Medlar and Sasano[3] who were the first to tackle this problem experimentally showed, by maintaining infected rabbits in an upright position for eight to ten hours each day, that posture was a factor in making some parts of the lung more vulnerable to tuberculosis than others, though the point was not pursued further[4] In the cases with completely calcified pulmonary primary complexes, Medlar found 10% with evidence of reinfection He also found that in 17 of 100 cases of known pulmonary tuberculosis in adults the healing of a primary infection must have been followed by true reinfection behaving like a second primary infection[5] Of the 100 patients 34, aged 16–64, had died as a direct result of primary tuberculosis[6], and from these and the 1000 sudden deaths he concludes that progressive primary pulmonary tuberculosis accounts for the majority of clinical cases in patients less than 40 years of age, while progressive disease from reinfection accounts for the majority of cases in patients over 40 years of age Medlar adds his authority to the belief that smooth apical scars are unrelated to tuberculosis[7]

---

[1] Medlar E M *Amer Rev Tuberc* 1955 71 no 3 part 2
[2] *Amer J Path.* 1926 2 101
[3] Medlar E M, Sasano K T *Amer Rev Tuberc* 1936 34 456

Medlar interprets the lesions of human pulmonary tuberculosis strictly in terms of his findings in rabbits He discards his earlier findings in guineapigs,[8] since the lesions there were of the abscess type which did not proceed to complete necrosis Now, in the light of a time sequence evolved from experimental lesions in rabbits some of which were vaccinated with B C G, the lesions in man take the following pattern The initial lesion is a minute area of lobular pneumonia in which neutrophils are the predominant cellular element, but monocytes are also present When the parasites are easily destroyed this lesion heals by resolution If the parasites are less easily destroyed an epithelioid mass forms, and, though it may long persist, it never enlarges and it eventually heals by scar formation Where the parasites reproduce in the initial lesion, necrosis occurs with lysis of many of the bacilli if all are killed, the lesion heals by calcification and fibrosis, if not all are killed, viable bacilli are carried along with the slough to new areas of lung parenchyma and the whole process is repeated, thus producing the complex lesions eventually found by the pathologist Liquefaction of the necrotic material depends on subsequent infiltration by neutrophils and must occur before sloughing In this description hypersensitivity to tuberculin is of little account (Rich[9] goes to the other extreme by implicating hypersensitivity as a most important factor in the degree of reaction) Thus Medlar minimises the importance of tuberculous granulation tissue and the monocyte epithelioid cells, while he emphasises the presence of polymorphs and the occurrence of necrosis Dissemination by the bloodstream is rare (apart from miliary tuberculosis), and by the lymphatics it is relatively innocuous, local expansion does not occur Dissemination is nearly always by way of the bronchi Medlar's illustrations are all at low magnification (× 1 5 to × 15) and details cannot be seen, different elements have to be distinguished by legend descriptions with references to rather indistinct colours This part of the monograph is unnatural and forced, and, with the repeated insistence on the time sequence, monotonous Those who do not wish to exert their own critical faculties should refer to the excellent description of the histological features by Florey,[10] who has himself done much work on this aspect and has inspired much from others Medlar's interpretation of cavity formation in man is also fitted to the development of cavities in vaccinated rabbits or in unvaccinated rabbits inoculated with few bacilli of low virulence the histological description is biased in the same way as that of the minimal lesions (Other recent discus of this topic include those by Pagel[11] and Clegg Despite this criticism of Medlar's interpretation of th structural changes, there is general agreement u his conclusion about the effects of streptomycin p aminosalicylic acid there is no morphological evidence that chemotherapy significantly affects a necrotic le once it has formed, though the non necrotic com (? perifocal reaction) vanishes more rapidly than in days before chemotherapy

RAYNAUD'S PHENOMENON

ALTHOUGH Raynaud's phenomenon is a comm complaint, in only a small proportion of people is th disability severe enough to bring them to the doct The majority of those so examined are in the idiopath group The attacks begin in adolescence and are pre cipitated by exposure of the hands or body to cold Although the recurrent colour changes, cold ache, tingling may be a nuisance, nutritional changes do develop Sometimes the Raynaud's phenomena ma come on in adult life and a detailed search must then made for the cause The digital arteries, whose abnorm response to cooling is incriminated in this condition, ma be attacked by many different lesions The chan in their behaviour is sometimes associated with organic narrowing or occlusion of the vessels, while some the colour phenomena can be more satisfactori attributed to an exaggerated response by the arteri muscle rather than to any narrowing of the lum More rarely, the occlusion of a large proximal arter such as the subclavian, may be the cause The dist between the occlusive and non occlusive groups ca be made quite simply by means of a reactive hypere test or, with great precision, by angiography

The ætiology of Raynaud's phenomena appearing in adult life is less easy to determine The persistent use of vibratory tools is one possibility which is usuall suggested by the patient's occupation Agate and Druett[14] have shown that a frequency of about 40 to 125 cycles per second is required to cause white finger In young men below 35, thrombo angiitis obliterans is the commonest underlying lesion Identical arteri changes are often present in the legs, and a history of attacks of phlebitis is common In some, the disease strikes with dreadful speed, and all four limbs may be lost in a short time, in others, the attacks of angiitis are widely spaced and the lesions small and isolated In older men atherosclerosis, which often picks out isolated digits, thereby giving asymmetrical Raynaud's phenomenon, is usually responsible Lynn et al[15] have lately suggested that "thrombotic digital artery disease" would be a better term when there are local nutritional changes and arteriographic evidence of obliteration of the digital arteries

In women thrombo angiitis obliterans is virtually unknown, although atherosclerotic digital lesions occasionally lead to Raynaud's phenomena Frequently, however, the white fingers make their appearance between the ages of 20 and 50 In such patients a careful physical examination may reveal other skin or vessel lesions, such as scleroderma, acrosclerosis, or disseminated lupus erythematosus, and in these the white fingers are only a minor part of the general systemic affection These diseases account for only a few cases, and many of the others will be found to have joint lesions, flexor tendon nodules, or a persistently raised erythrocyte sediment n rate suggesting a rheumatoid condition The onset Raynaud's phenomenon may indeed precede clinical ns of rheumatoid arthritis by many years, and the e diagnosis is apparent only after a long follow up r the remainder of these women no cause can be found the Raynaud's phenomenon which may or may not associated with structural changes in the calibre of the ssels The severity of the symptoms varies and some nes nutritional lesions or calcinosis circumscripta may use a good deal of distress Barnett[16] in a review of ite fingers due to occlusive digital lesions has pointed t the difficulties of differential diagnosis and emphasised at although a sympathectomy may relieve symptoms does *nothing to alter the march of the underlying* ocess.

DRUGS IN THE TREATMENT OF DEPRESSION

For the treatment of depression the value of the phetamine group of drugs is now established though st psychiatrists would regard them as ancillary to her modes of treatment Amphetamine itself has been rgely superseded by dexamphetamine sulphate which s *less side-effects and produces less tension, or by* ethylamphetamine hydrochloride These drugs are eful especially during the convalescent phase of a pressive illness in which a patient who has been treated y electroplexy has reached a plateau in his improvement hey are also valuable in mild depressive attacks, articularly perhaps in those of pyknic or athletic habitus nd especially when these reactions are the result of vironmental trauma Rudolf[17] has lately described e treatment of depression—mostly it seems of the lder type—with methylamphetamine in very large oses, which he has found as effective as electroplexy his has certainly not been the usual experience but ssibly few have employed the dosage given by udolf

In using amphetamines it has often been found that nprovement as regards depression was outweighed by an crease in the *associated anxiety and accordingly it* customary to buffer these drugs with short-acting arbiturates such as sodium amylobarbitone A number proprietary products embody this combination in single tablet or capsule Sodium amylobarbitone y itself is also widely used It often produces some uphoria but, even without this, the abatement of ension is encouraging to the sufferer from a depressive llness Moreover it acts and is excreted quickly which makes it less dangerous to the patient who may take n overdose. On the other *hand neither a barbiturate* or an amphetamine drug should be prescribed for any onsiderable period without carefully weighing the risk f inducing an addiction which can easily prove more ntractable and more dangerous than the original disorder[18]

The claims made for chlorpromazine have not all been confirmed by English workers but there is general greement about the value of this drug in treating ension Increasing experience suggests that its chief value lies in its use in association with other sedatives. When *given with sodium amylobarbitone it will often* give rise to tranquillity without clouding of consciousness Such a combination is particularly valuable in the treatment of outpatients or when dealing with severe depressions under general hospital conditions for if the patient can be relieved of unbearable tension the risk of suicide is small Against this as we lately pointed out,[19] is the fact that the drug is by no means always harmless and in some series has caused jaundice in something like 4% of cases As its ill effects are usually heralded by pyrexia the risks are diminished if patients are instructed to stop taking the drug if the temperature rises Pyrexia is seen probably in less than 10% of patients[20,21] but this figure is large enough to compel caution in the use of the drug for outpatients, and especially where there is any suggestion of liver dysfunction as in those older alcoholics in whom depressive illnesses develop Postural hypotension can be avoided by building up the dose slowly and cautioning the patient against exceptional physical stresses while chlorpromazine is being taken

CEREBRAL THROMBOSIS IN THE YOUNG

When a young adult has an unexpected stroke it is proper to search diligently for such causes as tumour, congenital vascular abnormalities, blood disease, embolic disorders syphilis, and polyarteritis nodosa Where no such disorder is found the cause is usually premature vascular degeneration The possibility of cerebral arteriosclerosis may be *overlooked in patients who are* not yet middle-aged Yet Irish,[22] in a review of 1000 necropsies on cases of cerebrovascular disease, reported 17 instances of cerebral thrombosis in patients aged less than 40; and of 30 patients with internal carotid thrombosis described by Gurdjian and Webster[23] 7 were under 40 Berlin et al[24] have now described 13 cases of cerebral vascular accidents in young patients, none was hypertensive, obese or diabetic, and in none did careful investigation reveal any reason for the accident except presumed arteriosclerosis The 1 death was of a patient aged 28 necropsy showed atheromatous narrowing and thrombosis of the basilar artery In a fairly short period of follow up there have been 2 non fatal recurrences

White[25] estimates that of all cases of myocardial infarction about 4% arise in patients under 40 years of age, owing to atheromatous coronary *thrombosis* Atheromatous cerebral thrombosis in youth seems to be little less common

EPSOM COLLEGE

Last year the many friends of Epsom College heard with concern of the school's difficulties and the uncertainty of its future Among the first to respond to the appeal sent out six months ago[26] was the Queen and on May 13 she again showed her interest in the college's welfare by going to Epsom to see the boys at work The headmaster Mr H W F Franklin showed the Queen and the Duke of Edinburgh a good deal of the buildings and grounds and those who use them and there was tea with the *prefects afterwards.*

The first hundred Epsomians assembled on Oct 10 1855 under the eye of the Rev Robinson Thornton the first headmaster and last week's Royal visit was a part of the centenary celebrations The story of these hundred years and the names of those who figured in it have been pleasantly set out in *Epsom College Register 1855–1954*[27] *another important* contribution to the marking of the anniversary But if things are to go on in the same effective way the school and the Royal Medical Foundation of Epsom College must have all the help *they asked for* in their appeal—and that was £150 000 The treasurer of the college is Dr Henry Robinson and his address is Epsom College Surrey

A MAN-CARRYING CENTRIFUGE

Opportunities for Extensive Research

At the R A F Institute of Aviation Medicine at Farnborough in Hampshire a new man-carrying centrifuge has been installed This is a development of great significance to aviation medicine in this country, for the centrifuge has enormous research possibilities The opening ceremony was performed on May 17 by Lord Thurso, formerly Sir Archibald Sinclair and Secretary of State for Air from 1940 to 1945

THE NEED FOR A CENTRIFUGE

The fact that pilots in fast aircraft may " black out " in tight turns has been known since the Schneider Trophy races of 1929, when aeroplanes flew at 350 m p h over a closed circuit It was immediately realised that this was a sign of retinal and cerebral anæmia produced by pooling of blood in the abdomen and legs, for which the centrifugal force was responsible With the mass *production of fast fighter aircraft these physiological* effects became an important hazard to pilots manœuvring at high speed, but little immediate research could be done because any investigation in a flying aircraft was difficult to perform, limited in scope, and indeed dangerous To reproduce the effects under laboratory conditions a centrifuge was necessary, and during the late war centrifuges were built in Canada and the United States, but it was impracticable at that time to build one in this country After the war plans were considered, and by 1947 the main features were agreed upon The apparatus was completed this year and the advances in design incorporated in it are a tribute to the skill and ingenuity of those who made it (M B Wild & Co and General Electric Co) and to the staff of the institute at Farnborough It is the most modern centrifuge in Europe and in some respects, such as the electronic recording, it is the finest in the world It has cost in all about £350,000

CONDITIONS OF OPERATION

Two subjects carried in observation cars, or gondolas, can be swung around a circle of 30 ft radius (fig 1)

The arm carrying these gondolas is 62½ ft long and 9½ ft square in cross section, and it is made of an open lattice work of tubular steel and light alloy It is pivoted on a central vertical pillar The mass to be rotated weighs 42 tons this is set in motion by a D C electric motor which de- 2200 H P

The maximum speed of rotation is 54 4 revolutions per minute, when the gondolas are travelling at 115 m.p.h. The speed can be reached in 9 seconds from rest The radial acceleration is then 30 times the force of the earth's gravitational field—i e , 30 g An acceleration of 5 g can be reached in 1 5 sec This means that the gondolas, which weigh 1150 lb (rather more than ½ ton) at rest, can reach an effective weight of over 15 tons These very high speeds will be used only for testing structures, and it is not proposed to

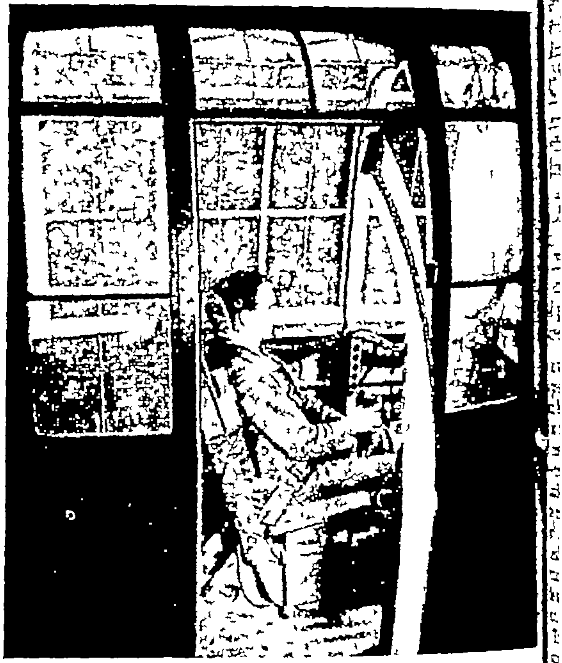

Fig 2—The cockpit of a gondola.

subject men to greater accelerations than 10 g (or possibly 15 g in the prone or supine position)

The gondola is fitted out as a cockpit (fig 2) and is *suspended on a pair of gimbals fore and aft* so that it tilts when it is being rotated The operation of the machine is in the hands of a controller who has an observation room looking into the centrifuge chamber Rotation may be automatically controlled by pre set cams, which determine the rate of acceleration to maximum speed and the time for which it is maintained. A joystick in the cockpit can also be used to alter the speed, but the man in the observation room does most of the regulation

An observer sits in a cabin on the rotating arm close to the axis and watches the subject continuously through the ' Perspex ' upper shell of the gondola, and the physiological measurements are recorded in a laboratory on the floor above the centrifuge chamber

All four members of the operating team—subject, observer, controller, and recorder—are linked by microphone and loudspeaker The subject's reports are constantly heard by all the others, but comments about him passed between, say, observer and recorder, can be kept from him lest they have an undesired psychological effect

PHYSIOLOGICAL INVESTIGATIONS

The centrifugal force required to cause black-out varies not only from pilot to pilot, but also from day to

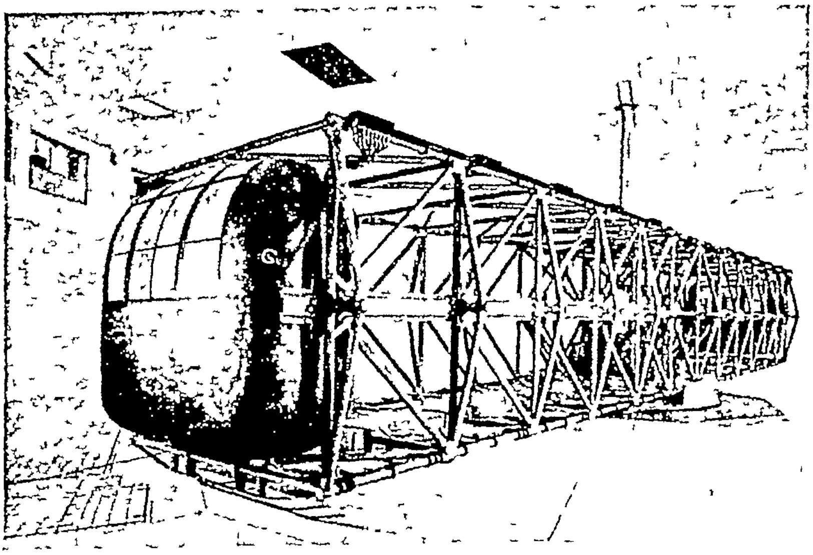

Fig I—The centrifuge chamber

y in the same man Few men can sustain a force of re than 5 g unaided and some will black out at 3–3 5 g hen wearing an ' anti gravity suit, which compresses e abdomen and legs and so limits the pooling of blood these regions, most pilots can sustain forces up to 6 g vertheless at one demonstration an experienced bject unexpectedly started to black out at 5 g even ough wearing a suit Apart from the effect on vision d consciousness the increased weight of the body akes speech difficult and the movement of the limbs mbersome

The measurement of the physiological variables eded to analyse these effects in a subject travelling at) m.p.h is difficult and their recording a major problem ll recording is done electrically and the signals carried leads along the arm of the centrifuge into the central llar They are then led out in the floor above by an genious system of slip rings in a column above the ntrifuge chamber To include the telecommunication rcuits there are 60 silver sliprings each with 2 silver rbon brushes leading to 30 mercury troughs each with spade type collector When it is remembered that .E.G and E C.G signals with a maximum strength of millivolt are led some 50–60 ft through this slip ring stem, the size of the technical difficulties in screening d protecting the signals from distortion will be ppreciated

In the recording room a 12-channel inkwriter (Ediswan) is present in use but a 24-channel photographic recorder will on be available The use to which these channels are put at the discretion of the experimenters. As an example one demonstration it was possible to record from 2 E.E.G ectrodes and 3 E.C.G chest leads. Then an estimate of head lood-flow was made by recording the opacity of the lobe of e right ear photo-electrically and also the pulsation of the rlobe Pulse-rate was recorded in two ways as a continuous ariable and periodically as an integrated count. The maining 8 channels recorded the acceleration of the subject e angle of tilt of the car and the pressure in the anti-gravity uit.

The arterial blood pressure is normally recorded by a apacitance manometer through an intra arterial cannula. he manometer and all the amplifiers are supplied by Southern nstruments Ltd.

In addition there is a cine-camera in the cockpit so that the ubject s reactions may be photographed at any time This enforces the clinical observations of the observer and also the ubjective account of his sensations given by the pilot through is microphone It is planned to include cino-radiographic ecording of heart and lung changes later on

OTHER USES

This standard use of the centrifuge for physiological esearch is by no means its only possibility The gondolas ay be suspended at 10 15, 20, or 25 feet from the centre s well as the end position of 30 feet By this means the ngular velocity component can be varied independently of the total centrifugal force by altering the radius The radial force = ω^2r where ω is the angular velocity nd r the radius of the rotation) As yet little is known of the effect of angular movement per se.

Moreover the gondolas may be replaced by a box like structure of the same dimensions as the cross-section of the rotating arm This is lined with foam rubber so that men may be allowed to move freely in a greatly increased gravitational field This is of particular value in training pilots to don parachutes or get through escape hatches under these conditions which are unfamiliar because of the great increase in body weight The rotating arm may also be used to subject structural devices to great centrifugal forces.

Thus, although the main purpose of the new centrifuge is to extend the research programme of the Institute of Aviation Medicine it will also be of value in training pilots and in testing their fitness to face this hazard of high-speed flying

HEALTH SERVICES OF NORTHERN IRELAND

LAST year the health services were severely criticised in debates in both houses of the Northern Ireland parliament Parliamentary control over the services was said to be ineffective and too much power was in the hands of nominated bodies , lack of coördination, extravagance, and administrative inefficiency were other criticisms made The minister of health in response to these strictures set up a committee under the chairmanship of Mr H G Tanner chairman of the South Western Regional Hospital Board [1]

In its report [2] which was issued last week the committee points out that the ministry of health and local government unlike its counterparts in England and Scotland, is not empowered to provide health services but only to secure their provision by others Thus hospital and specialist services in Northern Ireland are provided not by the ministry but by the hospitals authority and the tuberculosis authority which also provides ancillary services, notably bacteriological and blood transfusion services

Hospital Services

On the whole the committee found that the system had worked well The hospitals authority had shown itself energetic and enterprising Charges of irresponsibility and extravagance were unfounded It had been able to spend more money on capital developments with more freedom than the English regional hospital boards, and from 1948 to 1953 it had increased the number of beds by 10% But the committee considered that the authority's relationship with the ministry was anomalous and should be changed that its internal administration was cumbrous and that it had not always secured the full coöperation of hospital management committees The committee would not wish to see the authority stripped of its executive functions and turned into an advisory body But it recommends that the authority should become an agent of the ministry, for it considers it anomalous that final responsibility for expenditure should rest with the ministry and responsibility for the policy which largely determines expenditure with the authority

> In our opinion responsibility at the highest level for finance and policy must rest with the Ministry We subscribe to the principle that a service which is financed entirely from voted moneys must be subject finally to Parliamentary and therefore to Ministerial, control and we see no alternative to this which does not infringe constitutional practice and precedent and contain inherent possibilities of friction and confusion. If this recommendation is accepted it will establish an unbroken chain of responsibility from Parliament through the Minister and her Department to the Hospitals Authority and the Hospital Management Committees. The essential point is not that the Authority s present powers should be curtailed, but that it should exercise those powers under and on behalf of the Ministry rather than in its own right

The committee also recommends that the members of the authority should be reduced to 20 or at the most 24 ; that not more than a quarter of the members, excluding the chairman and vice-chairman, should be doctors or dentists that the term of office should be reduced from 5 to 3 years and that the basis of membership should be broadened and the committee system simplified The grouping of hospitals, it proposes, should be reconsidered with a view to reducing the number of hospital management committees A more equitable distribution of general endowments would help to establish an integrated service

---

[1] The other members of the committee were : Sir George Henderson and Mr J V H Mills LL.D.; Dr G C Kelly and Mr N Dugdale were joint secretaries

[2] Report of the Committee on the Health Services in Northern Ireland Cmd 334 Belfast : H.M. Stationery Office 1955 Pp 86 3s.

The committee suggests that distinction awards should not be made by the authority, but should be granted in Northern Ireland either by a single committee, with jurisdiction over the whole of the United Kingdom, to which Northern Ireland advisers should be attached, or by a committee appointed by the minister of health and local government

Tuberculosis Services

The tuberculosis authority, the committee proposes, should also become an agent of the ministry, with the majority of its members appointed by the minister and not as at present by local authorities A system of retirement by rotation should be introduced When the authority was appointed tuberculosis was a serious problem in Northern Ireland, and the authority has an impressive record of achievement Its success tends to diminish the need for its separate existence, but the committee believes that it still has useful work before it A substantial proportion of the tuberculosis beds are provided by the hospitals authority, and the committee is concerned about the possible ill effects of a prolonged separation of tuberculosis from general medicine Savings in operating and administrative costs should accrue from the amalgamation of the two bodies, and the committee believes that it would be in the best interests of the patients to treat tuberculosis not in hospitals set aside exclusively for that purpose, but in annexes of general hospitals In its view the functions of the tuberculosis authority in providing hospital services might be transferred to the hospitals authority within a period of, say, five years The committee was undecided whether clinic and domiciliary services should be vested in the hospitals authority or in health and welfare authorities

General Practice

The committee considers that the general health services board should become an agent of the ministry, that the term of office of members should be reduced from 5 to 3 years, that a third of the members should retire each year, and that a larger proportion should be lay members It recommends that the board should take over the administration of supplementary eye services from the hospitals authority

The board controls the admission of doctors to its medical list, and the committee agrees that the present control of entry into general practice should be continued for several years "*Its abandonment in present circumstances would undoubtedly lead to a renewal of competition from which none would gain in the long run*" But the committee regards control as by no means a desirable long term solution, and recommends that there should be a survey "directed towards the ascertainment of the conditions and quality of general practice"

ELECTION CANDIDATES

THE lists of candidates include the names of the following medical men and women

LONDON BOROUGHS

Bermondsey—Catherine Orr Ewing, M.B Lond (C)
Poplar—G F Vaughan, M.B Lond (C)

PROVINCES

Barking—* Somerville Hastings, F.R C.S (Lab)
Batley and Morley—* A. D D Broughton, M B Camb (Lab)
Buckingham—D G Evans, M D Lond (Lab)
Carlisle—D McIntosh Johnson, M.B Camb (C)
Gosport and Fareham—* R F B Bennett, B M Oxfd (C)
Hendon—Bernard Homa, M.R C S (Lab)
Loughborough—J D Cronin, F.R C S (Lab)
Louth—D R L M Poirier, M R C S (Lab)
Luton—* Charles Hill, P C, M D Camb (L and C)
Ripon—*-Colonel Malcolm Stoddart Scott, O.B.E., M Leeds (C)
Stoke on Trent, Central—* Barnett Stross, M B Leed
Walsall, North—F R Roberts, M B Birm. (L and C)
Warrington—* Edith Summerskill, P C, M R C.S (Lab)
Wells—Max Bresler, M.R C S (Lab)

WALES

Brecon and Radnor—W S Russell Thomas, M.B Camb (

SCOTLAND

Glasgow, Kelvingrove—* Walter Elliot, P C, M C., M.B. Glas (C)
Perth and East Perthshire—R D McIntyre, M.B. Edin (Scot Nat)
Renfrewshire East—J D Mabon, M.B Glasg (Lab and Coöp)

C, Conservative Coöp, Coöperative Lab Labour L, Li
Scot Nat, Scottish National
* A candidate who was a member of the last Parliament

The Wider World

CHINESE MEDICINE

D W JAMES
M B Lond
LECTURER IN ANATOMY, UNIVERSITY COLLEGE, LONDON

China, like India, has two systems of medical prac Side by side with Western scientific medicine exis indigenous system with a history covering many hund of years When the Communist government came power it was faced with a shortage of technicians in fields, and medicine was no exception An imme programme of expansion of medical schools and hospi was begun Graduates from these schools were tra in Western medicine, but the development and investigation of traditional Chinese medicine was also encouraged The Communist attitude is determined by th simple thesis that the experience of hundreds of year likely to contain things of value Their hypothesis not that Chinese medicine is anachronistic, but that its claims are worth investigation, so that anything usef it contains may be incorporated into the body of moder Chinese medical practice

HISTORICAL BACKGROUND

The first known Chinese materia medica is believed t have been written some 5000 years ago by the Emper Shen Nung (an English edition was published in 1911 The remedies it describes include opium, rhubarb, arsenic, and iron Hwang Ti, over 2000 years ago, ma have anticipated the discovery of the circulation of the blood, for, though he offered no experimental veri cation, he wrote "All the blood in the body is under th control of the heart The blood current flows co tinuously in a circle, and never stops" In ancient tim the Chinese practised inoculation against smallpox by insufflating dried scabs from a sufferer into the nos Cretins were fed on sheep's thyroid and in the fir century A D Hua Tu is believed to have used cannabis indica as an anæsthetic

Practitioners of Chinese medicine, like their Europe colleagues until recent times, served an apprentices of four to seven years The apprentice learned h profession from day-to day contact with his master a the routine of practice Though the scheme of instructi was thus ill defined, a system of government examinati and registration has existed for over 2000 years, and practice without registration has been illegal There we private medical schools teaching Chinese medicine i Peking and Shanghai, but after the 1911 revolution the gradually closed down, and between 1911 and 19 there were only eight qualifying examinations i traditional medicine, all held in Shanghai

THE POSITION TODAY

e Chinese government has encouraged a systematic tigation of the remedies and therapeutic methods of tional medicine Dr Wu Chih chung dean of the cal Institute at Senyang (Mukden) who studied at s Hospital and in the United States, described ese medicine as "a *previously neglected mixture of* rience and superstition, from which we are now g to extract and remould what is valuable—and e is a great deal that is of value. Since 1949 a ber of chairs in the history of medicine have been olished, and there is in progress an extensive survey he ancient literature

he Chinese believe that this approach will be of e than historical interest The investigation of itional herbal remedies is not a Communist innova . Many years ago ephedrine was isolated from the *ma huang* preparations of which have been used in a for centuries. But today such investigations are ducted on a large scale and already over 300 pre ptions have been studied on the recommendation of kers studying the old literature Scientists in the ing public health laboratories of the Academia Sinica m to have been led by this study to the isolation of a g giving promising clinical results against both the ebic and the bacillary forms of dysentery and they at present investigating a drug said to be effective inst pulmonary tuberculosis.

t is hoped that a study of the literature of traditional licine may be useful in other ways For example kers in Peking have surveyed methods of sewer struction practised in China from the Han dynasty yards on the ground that materials and methods may rediscovered which will throw no burden on the ited manufacturing resources now available

CHEN CHIU THERAPY

Perhaps the most striking feature of the present day itude to traditional Chinese medicine is the extension l revival of Chen Chiu therapy *Chen* means needling acupuncture, *chiu* means cauterisation or burning ese techniques have been practised from the earliest es and references to acupuncture by early writers gest its employment using stone needles before the covery of metals 700 sites for needling are described a treatise dating from the Sung dynasty and though upuncture was regarded until lately as empirical it was ieved to be of considerable value In treatment by upuncture needles are inserted into the tissues—the mber site and depth of penetration depending on the ease In some diseases the needles are rotated, or a der like herb may be wound round their protruding ds and ignited

In 1951 an experimental Chen Chiu institute was set by the ministry of public health and charged with the estigation of these methods The impetus to these dies came partly from the eclectic attitude to tradi nal medicine already described but perhaps equally portant was the influence of the Pavlovian school in ssia

Russian biological influence in China is considerable d every medical school and research institute now has soundproof Pavlov room The Pavlov school inter ts disease in terms of a disbalance between cerebral citation and inhibition and Pavlov himself used mild rmal stimulation in therapy His theories are held to ovide the necessary scientific basis for Chen Chiu erapy and to remove it from the domain of empiricism upuncture by virtue of its stimulation of the peri heral nervous system is held in China to be the method l choice to restore a disturbed balance between cortical citation and inhibition The Chen Chiu institute has laimed remarkable therapeutic successes in the treatment of such diverse conditions as rheumatism malaria hypertension tuberculosis, and paralysis agitans Figures published by the institute claim 90% cure of 5115 cases of malaria in army units, and 80% successful treatment of 263 cases of hypertension!

The practice of Chinese medicine is not limited to special institutes Some medical schools have departments of traditional medicine and their undergraduates receive instruction in its principles In the Mukden medical school a traditional practitioner holds the rank of assistant professor of internal medicine and has his own department. Chen Chiu practitioners have been absorbed into army and local government organisations, and the institute has trained 1400 of them since its inception in 1951

It seems unlikely that a hospital patient would be denied the resources of Western medicine if he seemed to need them, for Chinese medicine is regarded as con tributing to scientific medicine not as something which renders it unnecessary The 11th People s Hospital in Shanghai opened in 1954 and devoted to traditional practice, has the services of a consulting staff trained in Western techniques who confer with the traditional practitioners both to establish a diagnosis and to supervise treatment when necessary Bacteriological and radiological facilities are available But in the rural areas a traditional practitioner is often the only doctor

CONCLUSION

Though the Chinese clearly have a strong emotional attachment to a system of medicine which is so much a part of their history this attachment is unlikely to blind them to the results of scientific assessment of traditional techniques. Chen Chiu therapy has received a remarkable impetus as a result of the influence of the Pavlovian school, and it seems probable that for a time at least traditional medicine will colour the main body of Chinese medical practice

My thanks are due to the staff of the 11th People's Hospital Shanghai who supplied much of the information included in this article

---

Public Health

School Medical Service

IN his annual report for 1951 Dr C W W Jeremiah, school medical officer for Nottinghamshire refers to the difficulties of attracting young doctors to this work He points out that the shortage of doctors and nurses may give rise to the subterfuge that so much of routine inspection is waste of time—a mere question of rubber stamping the fit. But Dr Jeremiah observes, the value of the routine examination lies in the fact that a child can be evaluated as an individual and not as one of a crowd and he goes on to say

> His early defect can be considered in its proper perspective when the degree of its significance is not determined by the need or otherwise to issue yet another certificate prescription or letter to a consultant The organised methods of routine school inspection are designed to make full investigation and analysis possible even if at times the problem child does upset the time schedule And surely to *know* a child to be free from defect is a matter of no little importance to parents and teachers who have the daily responsibility of its care "

> so long as Medical Officers are required to carry out the functions of this Service it is *not sufficient to say* There is a career in this Service for you. It *must appear* so in the eyes of the young recruit to the profession. It can only appear so if he can see clinical responsibility worthy of his training and conditions of service more nearly approximating to those available to him in other branches of the profession with whose members he has to work in constant association

In England Now

A Running Commentary by Peripatetic Correspondents

THE main object of our journey to Spain has been to sit in the sun and do nothing—except cool off from time to time in the sea—but we had to see the Prado in Madrid, and that alone would have been worth the journey And while we were in Madrid I took time off to visit the department of medicine, run by Professor Jimenez Diaz

At present the department is divided between the University Hospital of San Carlos and the Clínica de la Concepción in the University City, which was opened a month or two ago It is a well-equipped and up-to-date hospital, but what most impressed me was the canteen, designed and decorated by the students of the School of Architecture Light, form, and colour produce a refreshing harmony Over the bar they had put a fresco inspired by Galenical animals, and another is planned of the plants that may produce asthma I wish we sometimes encouraged these fantasies, especially when I think of the "temporary" canteen buildings which disfigure some of our hospitals

We did not get to the canteen until 3 P.M., which is late for lunch even in Madrid, and though my morning had begun only at 10 A.M., everyone else had begun at 9 A.M. The main event of the morning after the ward round was the demonstration of some twenty cases by the senior assistants of Don Carlos and on each he gave his opinion There was some astonishing stuff a lot of hydatid disease, of course, but also a case of cutaneous leishmaniasis from Almería in the South, and other curiosities drawn from gastro-enterology, neurology, thoracic disease, and dermatology Medicine has not yet become fragmented here

The patients, as I saw them on the wards and at this demonstration, seemed to take an intelligent interest in the proceedings There was no attempt to spare their feelings in the discussions of diagnosis and prognosis, even when the import of these was very grave, but they remained unmoved Their attitude was impersonal rather than stoical

* * *

I like plumbers They have the spirit of the craftsman Of course they have much in common with my own profession I watch the plumber doing a lateral anastomosis with fervid admiration. Admittedly, he has certain advantages as a rule he can define and, as it were, seal off his field of operation The vital fluid with which he works may be temporarily cut off There are dangers none the less a mere pinprick in a ball-valve, hardly large enough to admit a staphylococcus, may lead to the destructive overflow of a cistern especially when its catheter is blocked by a bird's nest. It is in diagnosis, however, that our plumber excels Only the other day our hot-water tap in the bathroom became enfeebled to a mere trickle We called in the specialist who in a matter of ten minutes produced from its valve a beautiful specimen of phosphatic calculus

The craft is ancient and rich in tradition I am informed that the lion's head which adorns village standpipes, and used to be seen in elegant Victorian basins, is an offering to Leo under whose benign influence old Nile went into flood and spread its rich load of soil far and wide There are critics who allege that plumbers have not changed their ideas very much during the past two thousand years In houses they tend to festoon their pipes among the rafters—in places accessible only to frost. They have also a passion for what are called "long runs" This means that the kitchen tap has to be turned on for three minutes at least before any hot water deigns to appear But I like plumbers all the same!

* * *

The present epidemic in London is making life unbearable It's bad enough to have to listen in daylight hours to *Tishoo! Tishoo!* but it's infinitely worse to be woken at intervals during the night by a loud *Tishoo!* in the street. What! You haven't noticed it? You must live off a bus-route London Transport buses are being fitted with some new gadget (some kind of jet propulsion?) with the result that every time one of them stops and starts again it sneezes.

* * *

"Tell me," the newly admitted fellow patient cated a stout, motherly body, "is she a doctor,"
"She," I said, "is the Senior Surgeon."

The title was unambiguous enough to impres But his question revealed one of the odder aspects in the wards patients spend hours watching bodies moving before them, but they rarely them correctly Only the orderlies are labelled shoulder flash. Do registrars trembling on the consultantship realise that they are confused with hatched house-surgeons and technicians hunting for the path lab

They may, in a spirit of unconvincing democra that they do not mind, but if the most pote medicines is the doctor himself,[1] should not the know what dose he is taking? What is the effect condition of projecting the same feelings towards all white coats—let alone the first few confusing days he discharges similar quantities of psychic energy to white coats, covering the student, the dietitian, physiotherapist, and the barber? Should not all be labelled?

* * *

I was brought up always to carry two handkerchi one for blow and one for show—and I religiously them every week whether they need it or not Ne theless I feel uncomfortable when I see my fr ostentatiously blow their noses on medicated hy tissues This is not due to any narrow minded that only my ways are right, but to the certain know that I am about to suffer an attack on my personal Your annotation last week on poliomyelitis has com me however You point out that hygienic measures prevented people from getting themselves immunis polio during infancy and have thus converted inf paralysis into the much more serious disease—epi poliomyelitis If these medicated-tissue types get t way we shall find that the ordinary harmless com cold will vanish and its place taken by epidemic co So join with me all you handkerchief men and le fight for the common cold to the last sneeze.

* * *

Seventeen stones of placidity was our Maggie eighteen months she lay abed without a grumble an the end of this time we did a left-sided pneumonect on her You can imagine our pride when a week Maggie's discharge from the sanatorium we picked the local paper to read that it took four policemen hold her down in a drunken brawl

* * *

SONG OF A DEMICENTENARIAN

When I was young I took to my heels,
Danced the lancers and eightsome reels,
Tapped like a metronome, pranced on points,
And never gave a thought to the state of my joints
I was younger, brighter,
And very much lighter,
In those days

When I was young I ate what I got,
Regardless of whether it was fattening or not
I stuffed potatoes and I throve on bread,
And I never gave a thought to middle-aged spread.
I was younger, leggier,
"Bought-it-off the peg" ier
In those days

When I was young I talked very well,
Listened like an angel, and laughed like a bell,
When I felt like clowning I could rock the room,
And I never gave a thought to middle aged gloom.
I was younger, tarter,
And less of a martyr,
In those days

But I'm not dead yet, and presently I
Shall be an old party who'll never say die—
Who rollicks up to London and riots through the sh
And never gives a thought to stopping till she drops
I'll be older, merrier,
And spryer than a terrier,
In those days

Letters to the Editor

KWASHIORKOR

R,—

*Me me adsum qui feci in me convertite ferrum
O Doctor Federico Gómez.*

s the earliest importer of the word kwashiorkor" as you, Sir, were the first to perpetrate it in print) d I must defend in your columns its use by my friends, Trowell Dr Davies and Dr Dean

think Dr Gomez (April 30) is mistaken when he ciates malnutrition directly with overpopulation many areas where the disease exists there is no ' keen petition for food ' It often results because the nts do not know what food is suitable for the weaning d. This is admirably illustrated by Autret and Behar[1] uatemala.

r Gomez can rest assured that none of the English ors who are studying malnutrition in African children" any "romantic desire to perpetuate absurd expres of African tribes" What is there absurd ? This l means this disease It is defined as ' the disease child gets when the next baby is born ' And in t countries it has been found that this is indeed the ation often associated with its occurrence It has been fairly extensively investigated and it is proved o largely due to protein malnutrition But possibly is not the whole story Perhaps certain amino s are more important than others Perhaps certain erals, toxic drugs, or herbs will prove to be part of the ure Until we know more accurately what are the ors leading to this disease some people prefer to use word which conveys an idea without yet making ustified claims to detailed knowledge

ertainly other countries can produce whole regiments ames that convey similar ideas As the book referred shows, there are now numbers of generic as well as n names by which the condition or something ilar may be identified

ome of my medical friends were horrified at the word washiorkor" but now many of them have learnt to nounce it quite intelligibly I am sure they will enjoy ming to say "tzipitl

But beri beri is still called beri beri although we now ow it is due to aneurine deficiency Rickets (a word ed probably among primitive Anglo-Saxon tribes) is l called rickets though we now recognise it as amin D deficiency ' Onyalai ' as far as I know has serious rivals. What about ' yaws or even malaria ? ' Kwashiorkor is to some extent a fession of ignorance But I cannot see why because s African it is therefore unacceptable Scipio at any te would not have been surprised

The most puzzling remark in Dr Gomez s letter is when says " It cannot be accepted in the light of modern owledge that there are many types of malnutrition rely one of our main objectives is to identify and stinguish between the many and various types of alnutrition How can nutritional studies advance less we do so ? A case of beri beri a case of rickets case of anaemia each needs its own specific treatment he Ga people recognised a particular form of mal trition They called it ' kwashiorkor

London, W.C.1 CICELY D WILLIAMS

POLIOMYELITIS VACCINE

SIR,—Your American correspondent s report last week p 1018) regarding the Salk vaccine is hardly encouraging may also be pointed out that however dead the irus in the vaccine may be the giving of any kind of oculation is likely to precipitate paralytic poliomyelitis a relatively very small number of children who perhaps re already harbouring the virus One is led to believe that these dangers are less than the benefits of protection but when the protection is by no means 100%, the merits of the method and its statistics become debatable

As your correspondent points out many virologists favour the use of an attenuated live virus given by the mouth This is reported to be effective in provoking the development of antibodies without even causing an abortive illness It is certainly more effective than the Salk method, and may even involve less risk, for should an oral vaccine lead unexpectedly to a febrile illness there are still many chances that no paralytic disease will develop especially if certain precautions are taken When, however, poliomyelitis is precipitated by an inoculation the natural defences of the nervous system seem to be rendered ineffective, and nearly all such illnesses develop into a paralytic form of the disease affecting especially the limb used for the injection

It seems therefore that the oral method can be submitted to clinical trial with as little anxiety as is involved in using the Salk method and many will think that a test of this kind on a considerable scale is not only justified but is urgently called for Should an oral vaccine prove to be safe its administration within the first few months of life might well lead to the disease being conquered "

STAPHYLOCOCCAL INFECTION IN THE NEWBORN

SIR,—We have read with interest the letter by Dr Court and his colleagues in your issue of May 7 We are at a loss to understand why they have interpreted our article of March 19 as a recommendation that *all* infections in newborn babies in maternity hospitals should be treated *with erythromycin* ' (our italics) It was clearly stated that the object of the work reported was to test the efficacy of erythromycin in *staphylococcal* infection and to determine whether under the strictly controlled conditions of our experiment, erythromycin resistance would develop That it is not our normal practice to treat all cases of staphylococcal infection in the newborn with erythromycin or other systemic antibiotic therapy is evident from the fact that we specifically pointed out that, in most cases of conjunctivitis systemic therapy is not indicated and that we use local therapy in the form of chloramphenicol As conjunctivitis accounts for 60–75% of staphylococcal infection of the newborn systemic antibiotic therapy even if all other staphylococcal infections were treated by this means would be employed only in a minority of cases. We do not however treat trivial skin sepsis with systemic antibiotic therapy provided this clears up during the infant's stay in hospital, but no infant is discharged home with an active staphylococcal lesion of any sort untreated

It appears from the figures they give that Dr Court and his colleagues treat with chemotherapy or antibiotics approximately 75% of all cases of staphylococcal infection of the newborn occurring in their maternity units The proportion of our cases so treated is roughly similar although a little higher They use predominantly sulphacetamide ; we use predominantly chloramphenicol —both synthetic chemical substances both capable of inducing resistance in staphylococci Chloramphenicol however is in our experience the more effective and complete resistance of the staphylococcus to it is less likely to occur Sulphacetamide induces resistance to the other sulphonamides chloramphenicol does not induce cross-resistance to other antibiotics, as far as the staphylococcus is concerned Chloramphenicol [illegible] the advantage that it is unlikely to be used [illegible] therapy

We agree in principle that the use of [illegible] and antibiotic therapy should be [illegible] minimum but we have [illegible] antibiotics fairly extensively in neonatal staphylococcal infection Firstly, we are satisfied that minor staphylococcal infection of the newborn is potentially dangerous and that effective treatment reduces this danger The danger does, of course, extend beyond the period during which the infant is in the maternity unit, and Dr Court and his colleagues do not state for how long their 633 cases of minor infection were followed up

---

[1] F.A.O Nutrition Series 1954 no. 13 p 48

A few years ago when we adopted a much more conservative policy than we do now, we became alarmed at the number of infants who had serious staphylococcal infection following minor untreated staphylococcal lesions , and we reported a few of these cases[1] Over the past three years we have not seen serious staphylococcal sepsis develop in a newborn infant who has had minor staphylococcal infection adequately treated , but, to mention only one type of serious staphylococcal sepsis, we have seen in our medical pædiatric wards over the same period 5 cases of staphylococcal pneumonia (1 fatal) in the first month of life following untreated minor staphylococcal sepsis 2 other cases (1 fatal) were probably related similarly to minor sepsis The increased use of antibiotics over this period has not resulted in an increase of antibiotic resistance among staphylococci cultured from random swabs from babies and staff, as the accompanying table shows

STAPHYLOCOCCI RESISTANT TO CHEMOTHERAPY

Year	Sulphonamide	Aureomycin	Chloramphenicol	Penicillin	Streptomycin	Terramycin	Erythromycin
1951		6 %	26 %	88 %	21 %		
1954	23 %	9 %	17 %	85 %	25 %	10 %	

Secondly, we are concerned at the danger of allowing newborn infants with active staphylococcal lesions to return home carrying antibiotic resistant hospital staphylococci Since the incidence of hospital staphylococcal infection of the newborn is so high, infected infants will, on their return home, constitute a considerable reservoir of resistant staphylococci unless steps are taken to control their infection before they leave hospital A recent survey carried out in general practice in Edinburgh showed that 1 in every 3 children under twelve, exhibiting lesions judged clinically to be staphylococcal, was a contact of another case of staphylococcal infection at home The 1000 Families Survey in Newcastle, too, drew attention to the frequent occurrence of staphylococcal cross infection within families Somewhat paradoxically, therefore, rational antibiotic treatment of minor staphylococcal infection of the newborn may actually play a part in limiting the spread of resistant strains to the community

Prevention, not treatment, of neonatal staphylococcal infection must be the ultimate goal, but as yet that appears to be unattainable We have not, as Dr Court and his colleagues suggest, reversed our policy of 1953 We have in fact extended the principle of early treatment of minor staphylococcal infection We should certainly be prepared in the light of new evidence and new knowledge, or a better interpretation of existing knowledge, to modify or change our present practice, but Dr Court and his colleagues have given us no grounds for doing so

PAROXYSMAL MYOGLOBINURIA

SIR,—In their report of a case of paroxysmal myoglobinuria (April 30) Dr Berenbaum and his colleagues suggest the possible existence of an abnormal myoglobin in this disease, and interestingly found normal electromyographic patterns in the affected muscles twelve days after the attack

We have recently investigated a similar case in of 21, in whom the attacks were produced by cold exertion combined Electromyography of the quadriceps before the attack had passed off normal action potentials but of very low voltage μV) It was thought that this low voltage was con with the weakness of the affected muscles and th not significant

Myoglobin from the patient's muscle and examined electrophoretically against pigments from normal human muscle No difference in mobilities over a wide pH range of phosphate was found

Thus our patient showed no electrical abnormality his affected muscles, and normal myoglobin by methods of testing

ABUNDANCE AND WANT

SIR,—It would be difficult to find anyone catered for medically than the inhabitant of London, where 254 hospitals run between them, each week, some 2325 outpatient clinics specialising every, or almost every, ailment or illness under the There are 30 devoted, exclusively, to chiropody, hands and fingers, 4 to piles Each year, every is sent a time table,[1] complete with a map, setting detail specialty, location, address, hours for attend and telephone number of all these clinics He can select a competent one for whatever his patient may suffering from and send him there, fully confident he will receive the best expert specialist treatment advice

Of the 2325 clinics, 1000 deal more generally, medicine, surgery, midwifery, pædiatry, diseases of the chest, &c , while 1325 deal specifically with every conceivable condition or illness

Ear, nose, and throat	142
Eye	125
Skin	112
Orthopædic	104
Psychiatric	100
Physical medicine and physiotherapy	84
Teeth	77
Venereal diseases	75
Neurology (including 9 neurosurgery)	66
Diabetes	51
Varicose veins	36
Chiropody	30
Heart (including antenatal heart and 2 E C G)	28
X ray	27
Radiotherapy	26
Genito urinary	25
Rheumatism	22
Sterility	20
Plastic surgery	19
Speech therapy	15
Rectum	13
Geriatric	11
Hearing aids	10
Endocrine	10
Child guidance	9
Hands and fingers	8
Asthma and allergy	6
Special genito urinary (stricture, phimosis circumcision 2 cystoscopy, enuresis)	6
Tonsils and adenoids	5
Parenthood	5

Dietetic medicine
Anæmia
Hæmorrhoids
Massage
Whooping-cough
Tropical diseases
Ultraviolet light
Thyroid
Peptic ulcer
Relaxation
Contraception
Clubfoot
Infectious diseases
Infant welfare
Antenatal (36th week)
Vaccine
Breast
Sigmoidoscopy
Anæsthetics
Remedial gymnastics
Nasal allergy only
Bronchoscopy
Nephritic
Scoliosis
Hot wax baths
Epileptic
Hay fever
Electro-encephalography
Sinus
Juvenile rheumatology
Allergy in children
Resettlement clinic
Babies (feeding and management)
Premature babies

In addition to keeping the citizen fit, the State very naturally, interested in procreation Thus mothers babies, and children are extremely well cared for, addition, there are 20 clinics for sterility or subfertility Coincidently, 75 clinics deal with venereal disease, another 25 with genito-urinary troubles

It pays the State, of course, to tackle venereal disease and all this could not be better organised every lavatory directs the sufferer, man or woman, to est centre where he can have confidential treatment advice.

[1] Time table of Outpatient Clinics at Hospitals in the Gr London Area From King Edward's Hospital Fund London, 10, Old Jewry E C 2

nfortunately the State like most of us, cares little hose child weep, so his laugh We people who find faction in befriending the alcohol patient are appalled in this city of 8 million people not one of its clinics rs for the alcoholic or his helpless relatives If the were known it would pay the State to befriend ng countless others the man or woman unfortunate ugh to contract alcoholism There are in this country on half a million people suffering, directly or rectly, from its repercussions

t is no good suggesting that these people should apply ne of the many clinics for psychiatric trouble These r of course, what they can but they are not usually pped or inclined to deal effectively with this rewarding complex medical task requiring ' green fingers ' as l as persistence and perseverance Alcohol patients their susceptibilities and diffidences Like the rest ts, they require to know of a place where they will be erstood and not scolded Our modest plea is that ng the 2325 special clinics there should be one oted to their needs

H PULLAR STRECKER
Hon. Secretary,
kworth, Middlesex Society for the Study of Addiction.

A BARBITURATE ANTAGONIST

SIR,—Discussing the failure of ββ methyl-ethyl glutari le (Megimide) to act in a case of phenobarbitone soning recorded by Dr McElligott (April 16), fessor Shaw (May 7) remarks that 'at the end of days there would be little barbiturate in the body is not so Butler et al[1] estimate that the proportion phenobarbitone eliminated from the plasma in the rse of a day lies between 11% and 23% My own ervations suggest that the figure is approximately % per day[2]

pplying the latter figure in this particular case it will en that 27 grains of phenobarbitone would remain in the y six days after an initial dose of 72 grains assuming t for practical purposes, all the barbiturate was absorbed fact owing to the comparatively slow rate of absorption phenobarbitone shown in this case by negative urine ts for barbiturate on the evening of admission, it is very likely that 15% of the full dose was eliminated during the t twenty four hours and therefore the calculated amount aining at the end of six days is an underestimate

The patient is described as obese ; assuming that her ght was between 10 and 15 stone and that her body fluids resented 70% of this weight a conservative estimate of blood phenobarbitone level at the end of the sixth day ld be between 4 0 and 2 5 mg per 100 ml. Blood levels this order are frequently associated with quite severe ptoms of intoxication and sometimes with coma. It is noteworthy that the dose of megimide was administered hours after admission—i.e nearer the end of the fifth n the end of the sixth day in hospital

Admittedly anoxia and shock frequently contribute producing coma which is *disproportionately deep for* blood level, but I doubt whether there is much dence in support of Professor Shaw's further state ent that by this time [six days] however there ould have been extensive cellular damage—e g ebral œdema Were this true it is surprising that on this time she *showed fairly rapid improvement*

So many barbiturate antagonists have enjoyed brief opularity in the last twenty years that it does seem ust important to control new remedies by blood rbiturate levels—particularly since the results of purely servative treatment have been shown to be so good[3,4]

RUPTURE OF LAPAROTOMY WOUNDS

SIR,—Mr Walton (May 7) draws attention to adherence of the prolapsed abdominal contents to the wound edges as a feature of "burst abdomen ' and uses this as evidence for his view that the peritoneum is the most important layer of the abdominal wall My experience differs from his in that in some cases there were no such adhesions in many the adhesion was to the peritoneal edge, and in a few only to the subcutaneous tissue also The later the rupture the greater was the likelihood of such subcutaneous adhesions and in these cases the escape of serous fluid had told of the earlier disruption of the deeper layers The skin sutures, therefore had not been removed in an attempt to avoid a ' burst ' and to leave the patient, temporarily at least with the safer incisional hernia In one case only in the whole series had the skin sutures been removed before the rupture occurred From this point of view skin closure with interrupted mattress sutures was safer than with Michel clips supported with a few sutures, though it did not confer immunity from rupture

It is perfectly true, as Mr Walton states that if the peritoneum remains intact there will be no burst abdomen but there may be an incisional hernia. It is equally true that if the anterior rectus sheath remains intact there will be no burst abdomen ; nor will there be an incisional hernia unless the scar stretches later We have all had the exasperating experience of struggling to close thin peritoneum in an obese patient, when each stitch hole rapidly expands even though to distribute the tension over a wider area all sutures are inserted before pulling any of them tight To me it is inconceivable that in such a case the peritoneal stitch is not torn out by the first postoperative cough or vomit *yet few of these patients disrupt* their wound and if the anterior rectus sheath is sutured carefully to avoid gaps, it is my impression that not all of them develop incisional hernia. Peritoneum is known to regenerate quite rapidly and I believe that if the rectus sheath heals by primary union no great harm results. I suspect, however that this tearing of the peritoneal suture line is a common cause of adhesions to the scar

Mr Walton surely destroys his own case when he says and in all cases I have noticed the firm adherence of part of the prolapsed bowel or omentum to the edges of the peritoneum and the subcutaneous tissue Surely this suggests that some part of the peritoneum has given way at an early stage. Small gut or omentum protrudes and lies just deep to the skin This can occur only if the anterior rectus sheath also has given way We must consider however the possibility of the fascial layer giving way some days after the peritoneal layer If the skin holds still longer this is a ready explanation of Mr Walton's findings and is, I submit the likely explanation of the late group of cases. A well-sutured skin wound, though obviously not consolidated, is quite soundly healed in six or seven days and even allowing for the difference of tissue and of blood supply I think it fair to assume that the rectus sheath still supported by sutures will at this stage withstand some degree of abdominal distension unless there is some factor reducing the rate of healing In the series I described in my article of March 12 such a factor was present in the form of stress hæmatoma, sepsis, or depleted serum protein. Probably there is no sharp dividing line between the early and the late groups—it would be astonishing if there were—but the evidence from the small number of cases described is that in the early cases the rupture is due to the breaking or to the tearing out of sutures and in the late cases to some factor or factors delaying healing

Turning now to the last paragraph of Mr Walton's letter most surgeons including myself have the *impression* that transverse and oblique wounds are less likely to rupture than vertical ones but there are few statistics on this point and those I quoted[1] do not support the view I made no mention of methods of closing the abdomen as so many have been described and I had no evidence to offer of the merits or disadvantages of each but for the past two years I have been using a continuous horizontal mattress suture for both peritoneal and fascial layers with in addition several interrupted horizontal mattress sutures for the latter During this period there has been only one "burst" but this I shall regard as fortuitous only, unless the passage of several years more confirms the reduced incidence Mr Walton's other points agree with those stated or inferred in my paper

Hove A STANDEVEN

RADIOLOGY OF PLACENTA PRÆVIA

SIR,—We note with interest the correspondence which has followed our article of April 16 Our experience of placentography is limited to the past three years, but we have come to rely on the method to show which cases of antepartum hæmorrhage are due to placenta prævia and must therefore remain under observation in hospital In our article we described how radiology has helped in the management of cases of anterior placenta prævia delivered by cæsarean section

An important point yet to be determined, we believe, is the extent to which placentography can replace the final vaginal assessment by the obstetrician in the theatre Mr Percival (April 23) has suggested that there should be no "percervical" examination when clinical and radiological evidence points to a major degree of placenta prævia We appreciate his reasons for wishing to proceed to cæsarean section without delay and would agree that there are certain cases where this action might appear justifiable Nevertheless we consider that there is a need for caution in this matter

Despite the claims of Dr Blair Hartley (April 30) and the great contribution he has made to the radiographic localisation of placenta prævia, we are impressed by the difficulty in establishing by postural and soft tissue radiography the exact extent to which the placenta encroaches on the lower uterine segment It is the difficulty of defining precisely the lower edge of the placenta in many cases of placenta prævia which makes us believe that there is still a place for careful vaginal assessment before the final decision as to vaginal or abdominal delivery is made Without this vaginal assessment it may be difficult to agree upon what constitutes a "major" degree of placenta prævia For the individual patient it is important to avoid an unnecessary cæsarean section, particularly as placenta prævia is not a recurring condition and between 40% and 50% of cases can safely be delivered per vaginam

Even with radiographs of the superb quality produced by St Mary's Hospitals, Manchester, it is only in 30% of pregnant women after the thirty-second week that it has been possible to demonstrate placental calcification Moreover, the demonstration of placental calcification does not necessarily enable the lower edge to be identified, especially in cases of placenta prævia Until it is possible to do this precisely we believe that vaginal examination in the theatre is indicated

*** In an article in this issue (p 1045) Mr Percival and Dr Murray record their experiences of soft-tissue placentography —ED L

A VISIT TO KOLTUSHI

SIR,—I note Dr Foggitt's criticism last week of my letter of May 7 He makes a serious charge that I show a "doctrinaire disregard of facts" On the contrary, in the last paragraph of my letter, I stated a procedure enabling a person to *demonstrate* a fact disregarded by Pavlov and his followers I refer to the fact that a person who employs a technique of conscious guidance and control of reaction enabling him to guide the manner of the working of the self as a whole by means of the primary control of the use of the self, head forward and up, thereby controls the self in such a way that it may be *demonstrated* to work as a unity

It works, therefore, in a manner preventing the from interfering with the needs which are vital providing the freedom enabling the human ma work in the best possible way as a whole As a con "vital" processes such as digestion, respiration, and work in what may be *shown* to be the best way, and fore, in a way capable of preventing disturbances of function, incidents such as bronchospasm and the thought associated with what is recognised as schi

Freedom of thought and action are essential not "the scientific world" but in the world at large, described a practical procedure whereby a person provide himself with these advantages Dr Foggitt ca this for himself by employing the procedure I set down last letter If he has not enjoyed the experience nece to this end, both Mr F Matthias Alexander and I will be to *demonstrate* and discuss for his benefit the *objectiv* cedure involved If he is prepared to accept this invit he will discover that he will be required to show an unre "meticulous objectivity" in giving his attention to details of the procedure, if he wishes to employ it in a m enabling him to provide for his use a self working at it therefore, in a way associated with kinæsthetic infor about near and distant influences in the environment, external and internal, working in a reliable way, and, t fore, in a way enabling him to prevent himself from dominated by reflexes conditioned by his environment whose influence over him he would otherwise be ma Unless he employs the procedure with a meticulous atte to detail, he may very well find himself enslaved by r controlling his behaviour in a way that makes him in sense free

IRON-DEXTRAN COMPLEX IN MICE AND

SIR,—It would be unfortunate if Dr Nissim's ing article (April 2) were to pass without further con than that so aptly made by Dr Golberg and colleagues in their letter of April 16

The title of the paper, the dramatic photom the tenor of the discussion, and the brief concl summate to produce in the mind of the casual read impression that the administration of intramuscular might be followed by the development of testi atrophy in a male patient

We have found that, despite Dr Nissim's reserval at the beginning of his discussion, this impression already been gained by those who have not cal that the same relative dosage in man would in injection of between 30 and 200 times as much as w ever be given clinically, given moreover to patients a deficiency of iron The inference, therefore, that iron compound apparently interferes with the r metabolism of the endocrine cells and upsets sp togenesis" is unreal when applied to clinical m and, is an example of the way in which the acad pharmacologist may become divorced from the realit practical therapeutics

Furthermore, Dr Nissim states loosely that deposition of iron in the testes after the administra of imferon reminds one of the *deposition of iron in testes* [my italics] and testicular atrophy in hæ chromatosis" This statement could be taken to his results in mice with gargantuan doses (doses ma be noted, only possible because the preparation is of toxicity) to those which might be expected in man It moreover, a misstatement of fact as iron depo does not occur in the testes in hæmochromatosis and Sheldon[1] pointed out, the only appreciable iron dete able in the testes is small quantities in the vessels It the experience of Dr Mary K Macdonald in the de ment of pathology, University of Edinburgh, and myself that iron deposition never occurs in the tub or interstitial cells of the testes in hæmochromat and, when the patient is hypogonadal, the testic atrophy is probably secondary to pituitary infiltra on This infiltration which may be very dense o noted by Sheldon and further commented upon bble[2] as the probable explanation of the hypo m of hæmochromatosis. Dr Nissim assures us ren in this type of experimental siderosis no y deposition of iron is found

CANCER

—Mr Malcolm Donaldson's challenge (May 7) to ychiatrists to join him in the study of the effect er education on the public is most welcome This ign is going through the same phase that marked esigned to give accurate information to the public nereal disease tuberculosis, and insanity Even e subject of these illnesses is in some quarters ched with bated breath One by one following ement, the 'bad objects upon which are ted the inner fears of destruction are being replaced ers

late Dr John Rickman put the position clearly r columns just before the outbreak of the late war he pleaded for the maximum information about the g dangers pointing out that when this was available ividual could summon resources to face the situa ithout evasion During my ten years as a family an, I frequently found that frankness and the of as much verified information as possible led to inution of strain in the doctor patient relationship nt this by bitter experience following the use of n and subterfuge which I rationalised as being the t approach to a suspected or confirmed cancer case

ALFRED TORRIE.

—Until I read the article by Mr Donaldson s in favour of educating the general public, hen a surgeon admits he underwent an explor laparotomy for a non-existent gastric carcinoma auses for thought Surely it is in members e medical and nursing profession and their rts that fear of cancer is most prevalent and most tent If those who are more or less fully educated s subject suffer most it is folly to increase know in the general public In the National Health re any patient with a symptom he cannot himself in will be very likely to consult his doctor but if s a symptom he thinks may be due to cancer he is ly afraid to be told what he fears the truth may be aits till it disappears or gets worse Thus the less verage man or woman knows of the early symptoms ncer, the more likely will they be to seek medical e early This is not very reasonable—but then especially frightened man is not a very reasonable al

dresbury
stan

HAZEL B BAKER.

,—The subtitle The Psychosomatic Disease to Donaldson's article reminded me of a patient in her le seventies who died recently from multiple ndaries from a carcinoma of the colon Her illness been slowly progressive and she had had an opera to relieve the obstructive aspect of it nine months iously On her death bed although she was unaware he diagnosis she was quite certain that she knew when this trouble with which she was dying had originated This she stated quite categorically was seven years ago when the minister of the church, which she had reverently cared for for many years and which she had many times scrubbed on her hands and knees, told her very gruffly to leave and not to come back Thought of this incident grew in her mind until it was all consuming in much the same way and at much the same time as the cancer developed and consumed her body

We know that suggestion can remove at least certain innocent growths on the skin and can cause 'burns' without heat. Is it possible that it can also cause abnormal growths in the body?

In this case I expect my colleagues to agree with me that coincidence and the desire to blame somebody for one's troubles are the most probable explanations—but I would be interested to hear of any similar experiences

AGAMMAGLOBULINÆMIA

SIR,—In a review of the literature on agammaglobulinæmia Grant and Wallace[1] pointed out that human malnutrition is associated with low gamma globulin levels and suggested that this might cause increased liability to infection Some recent investigations have shown that gamma globulin levels are usually normal in undernutrition[2] and normal or high in malnutrition[3,4]

We have tried to assess antibody production in children suffering from malnutrition (kwashiorkor) For a variety of reasons we were unable to study antibody response resulting from antigenic stimuli such as typhoid vaccine, diphtheria toxoid or other substances commonly employed for this purpose We therefore chose isohæmagglutinin levels as an indication of the ability to produce antibody

Isohæmagglutinin levels were determined in 15 severely malnourished African children aged eight months to three years and in 3 normal controls of the same age-group All titrations were carried out at the same time and on the same test cells The results were as follows:

Malnourished Children

Group	*Anti A titre*	*Anti B*	*Group*	*Anti A titre*	*Anti B*
A		1/16	O	1/16	1/32
A		1/4	O	1/2	1/1
A		1/128	O	1/64	1/128
A		1/16	O	1/16	1/16
A		1/4	O	1/8	1/8
B	1/64		O	1/32	1/32
B	1/8		AB		
B	1/16				

Normal Children

Group	*Anti A titre*	*Anti B*	*Group*	*Anti A titre*	*Anti B*
A		1/32	O	1/16	1/8
A		1/32	O	1/512	1/512
B	1/1				

Gamma globulin levels as determined by paper electrophoresis in the malnourished group were normal or high

With the exception of 1 of the controls in which the titre was much above the average the isohæmagglutinin titres in the malnourished children did not differ significantly from those of the controls or from those usually encountered in this population and therefore did not provide evidence of impairment of antibody production

In the Medical Research Council report[2] it was shown that in undernourished populations antibody production is somewhat impaired but not sufficiently to increase susceptibility to intercurrent diseases

UTERINE CIRCULATION IN LATE PREGNANCY

SIR,—Dr Morris and his colleagues (Feb 12) suggest that some trigger mechanism is responsible for the sudden onset of eclampsia The sudden release of cortical and medullary adrenal hormones by histamine or acetylcholine would be one explanation

The primary rôle of adrenocortical hormones in the genesis of œdema is proved by its appearance, as a side effect, during corticotrophin (A C T H) therapy of diseases of very different ætiology In these cases, there is no question of a reflex mechanism, but only of a hyperfunction of the adrenal cortex Clearly, adrenocortical hormones, such as hydrocortisone, are able to pass through the wall of the capillaries and into the cell, drawing with them sodium, serum, and a varying quantity of serum albumin, against the osmotic pressure of the serum proteins

Benzodioxane proved to be unreliable in cases of phæochromocytoma, giving false negative results [1 2] The rise in the blood sugar level, which has been repeatedly confirmed, is best explained by liberation of adrenaline during the preceding attack Macchiarulo [3] demonstrated the presence of adrenaline in the blood after an attack Professor von Euler has told me that this subject has been investigated in New Haven, but so far as I am aware nothing has been published Medullary hormones are elusive, because they are soon destroyed by the mono amino oxydase, in this light, the sudden drop in blood pressure after an attack must be explained, and there is a better chance of demonstrating medullary hormones if blood samples are taken immediately before or during an attack

There is indeed some controversy about the question if the excretion of urinary corticoids is increased during toxæmia, as compared with normal pregnancy The methods now in use are unsatisfactory, and more specific techniques are being developed (by Nelson and Samuels, for example) for hydrocortisone—as many believe, the natural cortical hormone A second objection is that most of the cortical hormones are retained in the cell out of reach of these reactions That the adrenals are in a state of hyperfunction during pregnancy is confirmed by the amount of uropepsinogen excreted in the urine, this is increased in all cases of hypercortism of whatever cause, and during pregnancy [4]

In my opinion, the statistics of Rh incompatibility show that toxæmia does occur in multiparæ The histaminolytic index, although it rises in pregnancy, may be even lower during toxæmia than in normal pregnancy, this makes it more probable that, during toxæmia, histamine may persist if it is produced in large quantities by an allergic reaction In these circumstances histamine will be available to liberate adrenal hormones Lack of histaminase immediately after delivery may account for puerperal eclampsia, and lactation causes renewed adrenocortical hyperfunction By the close relation of cortex to medulla, a vicious circle may easily result

Much work is being done on the influence of the adrenocortical hormones on renal function There is evidence that glomerular filtration is influenced by large quantities of cortical hormones serum albumin passes through the walls of the glomerular capillaries into the tubules, and proteinuria (also a side-effect of corticotrophin) results The renin hypothesis is not generally accepted [1]

Adrenocortical hormones increase sodium loss and reduce œdema in nephrosis by suppressing the existing hyperfunction of the adrenals and causing atrophy of these organs [5] Renal ischæmia may be caused by freshly liberated noradrenaline, which produces generalised vasoconstriction Histamine, or some H-substance, which can be neutralised by antihistamine, is able to do this too, but is at the same time responsible for reducing blood-pressure by capillary dilatation In eclampsia hypertension predominates

Methacholine ('Mecholyl') can also liberate adrenal hormones, and probably acetylcholine too When much acetylcholine is present in the uterine muscles, the capillary walls allow red cells to pass

Neostigmine prevents the hydrolysis of acetylcho- when, in cases of amenorrhœa, neostigmine injec given on two succeeding days, so much acety accumulates in the uterine muscles that uterine not true menstruation, follows

Is it not possible that abnormally large of acetylcholine, the product of some allergic may be responsible for a Couvelaire uterus or haemorrhage, with disturbance of the normally placenta? The appearance of the internal orga closely resemble that found in the Schwartzmann phenomenon

REACTION TO VITAMIN B_{12}

SIR,—The anaphylactoid reaction following the tion of refined or crude liver extract is well I have not been able to trace in the literature reaction following vitamin B_{12} injections R however, I have seen a patient who has been vitamin B_{12} injections as well as to injections of or crude liver extracts

Briefly, the patient has suffered from pernicious the past thirteen years She was treated with extracts for eight years and then had a sensitivity after each injection This took the form of a anaphylactoid reaction with urticaria of the skin ment was therefore changed to vitamin B_{12} inj my surprise twelve hours after each injection she precisely the same form of reaction as after extracts This happened on numerous occasions T ment was then changed to an oral preparation of liver ('Pabryn') and no further trouble has been The blood count and hæmoglobin concentration have satisfactory on this treatment

PHENYLBUTAZONE AS ANALGESIC

SIR,—Phenylbutazone ('Butazolidin') is a valuable addition to the treatment of like cortisone, it has certain risks Some years use purely as an analgesic was recommended I followed the method ever since and I find that greatly appreciated by patients, whether they rheumatoid arthritis or osteo arthritis One tablet is given night and morning until the pain is but the drug is not given for more than three days total of six tablets does not give relief, then p butazone is useless in that particular case If successful, however, then after a period of anyth a week to a month or longer, whenever the pain the same course may be repeated

Another extremely valuable use for phenylbutazone severe and lasting reaction *follows the injection* of a vaccine Anti rheumatic vaccines are of considerable sometimes, owing to hypersensitivity, they are not even in minimal doses In such cases, a 200 mg table at the *time of the injection*, and another the same will be found to be successful in preventing reaction. T not appear to suppress the euphoria and relief which *follow a suitable dose Of 20 hypersensitive* cases this way over the last two years, none have failed to

This naturally leads one to speculate on the m action of the drug Does it suppress the antigen-a reaction and thus prevent radical cure or perhaps down? I am grateful to Dr W S Stoddart, of Geigy, for sending me a quotation from a recent a Fabre and Berger [1] in which they show that the a antibody activity continues in serum-sensitive treated with phenylbutazone just as well as in the They suggest that the drug in some way reinfo impermeability of the capillaries, quoting the w Franceschetti and Chodos [2] who have reported an ution of capillary permeability, as tested by the ge of fluorescein in the anterior chamber of the eye. low we assume that the manifestations of rheumatic es are at least in part, the result of localised ons to an infective factor, then slowing down the ption of antigen should decrease the reaction caused too sudden combination with the antibody con in the affected cells

VERHYDRATION AND UNDERHYDRATION

k,—Those who are relatively isolated from advances edical thought and knowledge must be very grateful rofessor Bull for his Goulstonian lectures published ur issues of April 9 and 16 For me the lectures vividly clarified the understanding of the basic ology underlying the many diverse conditions ribed

those unfamiliar with the subject (*as I am*) the of the terms ' overhydration and underhydra may, however be a bit confusing When referring intracellular compartment overhydration ' is used cribe an abnormal excess of water relative to total lable osmotic activity of that compartment (that sentially, a state of hypotonicity) whereas this , when applied to the extracellular compartment s to a state of increased volume accompanied by a ortionate increase of total available osmotic activity is, an expansion *without* change in osmotic tension) le no etymological objection can be made to the inology used by Professor Bull, I feel that a slight ge may make the subject clearer for many readers

would suggest that for any fluid compartment, erhydration be absolutely restricted to those s where there is a reduction of the osmotic tension he compartment under discussion—i.e where there excess of water relative to total available osmotic vity Where the reduction of tonicity is due primarily reduction of total available osmotic activity and to an excess of water relative overhydration ht, perhaps be used and where the reduction of city is due primarily to an excess of water absolute rhydration ' might be used Similarly underhydra would be absolutely restricted to those states re there is an increase of the osmotic tension of the partment under discussion If the concept of osmotic librium is accepted—that is to say if it is accepted t there is always either zero osmotic gradient or else a stant unchanging gradient between the fluid com tments—then it must follow that (using this termin gy) an overhydration of one compartment would be ariably accompanied by an equal overhydration in other

y suggested terminology now leaves us without a term to cribe those states classified by Professor Bull under the eral heading of extracellular overhydration and without rm to describe some of those conditions described by him xtracellular underhydration I suggest that when reference being made to changes in the volume of a fluid compartment terms "expansion and contraction should be used ere the expansion or contraction is unaccompanied by a nge in osmotic tension one might if this were necessary clarity refer to iso-osmotic expansion or contraction; re the change of volume is accompanied by a change of motic tension the appropriate prefix hyper-osmotic or po-osmotic might be used or alternatively the words with underhydration or with overhydration" might be ded, preserving the rigid definition of underhydration and ehydration given above

Thus for example severe sodium depletion without restric n of water intake would lead to a state to be described as po-osmotic contraction of the extracellular compartment or extracellular contraction with overhydration—an intra- llular overhydration also of course resulting Sodium pletion with restricted water intake would lead to an iso-osmotic or hyper-osmotic extracellular contraction or alternatively to extracellular contraction without or with underhydration

The advantage of this terminology is that it would pin point more clearly the essential biochemical abnormality and indicate the appropriate treatment as the following examples show

Professor Bull classifies the œdema of congestive heart failure under the general heading of extracellular overhydration This might suggest that the basic abnormality was an excess of water and that the correct treatment consisted in restricting water intake Using the suggested terminology this condition would be referred to not as extracellular overhydration because there is no essential reduction of tonicity but as extracellular expansion The term extracellular expansion would help to emphasise that the œdema could only be corrected by removal from the body of some of the extracellular osmotic framework (or osmotic stuffing as Black aptly describes it [1])—that is, by depleting the body of its excess sodium. The term overhydration (unqualified) would be restricted to those states where there is a simple excess of water throughout the body and where treatment would consist in withholding water and allowing the patient to dry out

The production of extracellular contraction accompanied by intracellular overhydration is a serious risk in modern surgical practice This risk arises from the emphasis at present being laid (quite correctly when conditions are appropriate) on a liberal intake of hypotonic fluids. The condition results when a liberal intake of hypotonic intravenous fluid is begun *before* a severe extracellular contraction has been re-expanded. The circulatory renal insufficiency prevents the water being excreted, renal function may be depressed by the resulting fall in serum sodium and the patient may die from water intoxication If the *condition is* allowed to proceed to an extreme degree the only effective treatment may be administration of hypertonic saline (e g 5% NaCl solution) a fluid which may not always be readily available

It cannot be too strongly emphasised that 5% glucose solution when injudiciously administered at the wrong time to a severely salt-depleted patient is a potentially lethal fluid During the past year I have seen several surgical patients who have been on routine intravenous fluid therapy for some time with serum sodium levels below 130 m.eq per litre While several factors have doubtless contributed to the production of these hypotonic states (e g , early postoperative water retention [2] severe potassium depletion and "symptomless hypotonicity' [3]) one factor has been a failure to re-expand a contracted extracellular fluid volume before giving 5% glucose solution The use of the term ' extracellular contraction in place of extracellular dehydration would help to emphasise the importance of repairing the osmotic framework of a contracted extracellular space

When I was a student the only intravenous fluid which we used was normal saline or glucose in normal saline While this may have prevented us treating or preventing intracellular underhydration it did at least, make unlikely the production of those very serious states of intracellular overhydration.

One other point needs to be emphasised with reference to extracellular contraction in the surgical patient This is that in most patients the loss of water is greater than that of sodium relative to the normal Na/water relationship of the E C F " [2] In other words, extracellular contraction in the surgical patient is usually hyper-osmotic or iso-osmotic and it follows that the serum Na level may be valueless in diagnosing the condition or in estimating the degree of sodium depletion which has to be made good. This point is clearly implicit in Professor Bull's lecture but it is a point that is sometimes overlooked the false assumption being made that because the serum Na level is normal or raised saline administration is not indicated.

This letter is little more than a quibble over terminology Terminology however may be important and I

2 Le Quesne L P Fluid Balance in Surgical Practice London 1954

3 Wynn V., Rob C. G *Lancet* 1954 i 587

feel that there is a need today for one which is accurately defined, widely accepted, and reasonably descriptive, so that we can describe those water and electrolyte abnormalities which modern knowledge enables us to diagnose from the history and clinical and biochemical findings

Tyrone County Hospital, Omagh W S DAVIS

CANCER RESEARCH

SIR,—The time surely has come for a protest against the present methods of cancer research The large sums of money expended on the upkeep of the ever expanding wilderness which laboratory workers are creating would surely be better spent in building hospitals for patients suffering from malignant disease It is useless for anyone who has no knowledge of cancer as it is encountered clinically to endeavour to find the cause by experiments on animals

After long years of research, which have proved absolutely fruitless, it is high time that the laboratory method of investigation was abandoned In fact, quite a number of these laboratory workers have no medical qualifications, while several are not specially interested in cancer as a human disease Let us get back to the bedside and learn the earliest symptoms of cancer so that we may operate early and prolong the patient's life at least, if we cannot actually cure him

Edinburgh JAMES BURNET

SHOE DESIGN AND THE GREAT TOE

SIR,—In this correspondence particular emphasis has been laid on the effect of shoe shape on the hallux In my store we have perhaps an unusual opportunity for observing the effect of shoes on the development of children's feet, for we have a wide variety of British, Canadian, and American shoes Also we see infants before the weight-bearing stage and adolescents going through the transition from children's to adults' footwear

I suggest that no conclusive relation between the development of a foot and the shoes it wears can be obtained unless the condition of the foot at birth and before weight bearing is known More and more we are encouraging parents to let us see their infants' feet before they wear any kind of shoe so that we may be forewarned of possible difficulties that may be the result of intra-uterine distortion of the leg and foot and of noting the presence of any inherited characteristics

Apart from infants born with a degree of hallux valgus, there does seem to be some connection between even a mild degree of forefoot varus and subsequent realignment of the hallux when the forefoot varus persists We do not usually refer to this condition as a metatarsus varus, because it is really a complete "distortion" of the whole forefoot and mid tarsal section of the foot

There are two schools of thought regarding what, if anything, can and should be done about this type of foot, which we see in ever increasing numbers One practice is to put the foot into a shoe having a similarly "inswung" forepart, this seems to be a definite trend among British shoe designers The other view is that by stretching the foot in abduction and wearing shoes designed to provide the same amount of traction, the foot will revert to its normal alignment and consequently be less susceptible later to the influences of "out swung" shoes

Our experience of both methods is that the "inswung" shoe merely encourages the adducted position of the forefoot at a time when the foot is beginning to "set" When the child can no longer obtain such shoes, the change to conventional "outswung" is even more drastic, and distortion of the phalanges seem unavoidable Even if manipulation of the adducted forefoot is not carried out, the wearing of straight-lasted shoes, designed to direct the forefoot in a straight line, starting from the heel forward through the midtarsal section and finally at the head of the first metatarsal, gives some assurance that by the age of four the basic structure of the foot is as close as possible to what is generally accepted as "normal"

That shoes do influence foot shape appears The question seems to be "how much of the toes can be tolerated without causing function?" It is unrealistic to assume that the will ever accept the principle of "sensible" shoe worth-while period

I would like to mention the tremendous follow in Canada for the work of Mr Denis Browne. I more attention was given to minor congenit abnormalities attributed to intra uterine pressu these conditions were recognised from the sta measures taken to correct them, a large propo foot and shoe troubles would disappear

Kiddies' Shoeland,
North Vancouver,
British Columbia

ROY A

HALLUCINOGENIC DRUGS

SIR,—Professor Elkes and his colleagues have attention in their letter of April 2 to the dang treatment with lysergic acid diethylamide (LS Little has been published about the delayed re the report by Sandison et al [1] being a notable exc I should therefore like to record my interim find some of the phenomena Although they are b limited experience, they may serve as a warning, problems involved call urgently for investigation

The 8 patients in this series received LSD orally in *50–500 γ while fasting An interval of at least* sev separated doses after the trial ones Patients were all react with the minimum of interference necessary to injury or *accident Accounts of* experiences were o late on the day of administration in some cases, but found better to get written reports later and supplemen by oral discussion

Experience during the acute phase followed the pattern, but personal experience was dominant, even the early toxic hallucinatory patterns, som dream-like situations were acted out violently, lea from dreams before treatment began, and calling for pro measures

Experiences more than twenty-four hours afte administration of LSD could be grouped as follow

(1) *Mood swings* similar to those under acute drug occurred two or three days later It was not always to correlate these with environmental events. Both and euphoria occurred, the latter being often the less and insidious in its effects

(2) *Regression to childish behaviour* without other —e g, playing boats in the bath with the soap-dish quarter of an hour before realising that this was This was noted first nearly a week after taking any drug

(3) *Visual hallucinations* took several forms (*a*) *R to childhood* visual hallucinations, solid and coloured objects detached from their context—e g, a stepladder, elephant sitting on a tub These sometimes later built complete episodes, and were dated on the completion episode (*b*) *Complete episodes,* with auditory and hallucinations, usually growing from (*a*), and ac appropriate affect Development of experience had a sory quality, directing the attention, and excluding (*c*) *Hallucinations of fantasy,* comparable to dreams larly some "archetypes" (*d*) *Hallucinations of small* —crabs, cats, and insects (*e*) *Hallucinations of thou tents* in images—e g, a parade of various suicidal

It is doubtful whether (d) and (e) were due to LSD more like the familiar toxic type of hallucination, and after heavy sedation with barbiturates and insomnia patient insists that the hallucinations were similar to in acute LSD intoxication) They did not clear 'Parenterovite,' while the motor symptoms of barbi overdose did (*c*) occurred in a hysteric who had pre demonstrated a considerable capacity for visual pro In general it has been considered safer to accept as part LSD reaction, only experiences clearly related to p experiences, continuing previous dream material, or in the acute intoxication

---

[1] Sandison R. A, Spencer, A M, Whitelaw J D A. J ment 1954, 100 491

Auditory hallucinations have been included above as a of complete episodes. Another form is the hearing of , often later related to emotions associated with earlier ences.

Body image and time changes —It was difficult to separate ling that the body was smaller from the idea that the as younger In some cases age seemed different without sation of bodily change; in others both were changed the patient felt smaller age two and could not talk to . But I have not yet seen a regression to childish speech haviour

Illusions and misinterpretations are mixed with hallu tion, and may lead into it Objects change in shape and ne meaningful images of past events or change into entations of associated ideas. Thus a pair of stork vases ed into babies." Other experiences were more within al range—e.g a plant against a shed appeared in the like a white unicorn

Somatic changes included subjective sensations of swell of the hands. Erythema of the fingers, previously noted e patient changed in character as relevant material ed. Objectively swelling and discoloration of one e followed an hallucinatory experience of violence by other (this was confirmed by the patient's husband)

Time and space —Quite early in treatment one patient ised that her judgment of speed was unreliable, and ould not cross roads when vehicles were in sight This ed for long periods At least during the more violent of abreaction time was indefinite. Preoccupation or mindedness may persist for weeks a patient may a bus to draw up and depart and then realise that she ssed it.

for the time relation of delayed reactions in rela to the ingestion of the drug they may continue the day, but in 1 case they were entirely inhibited for days.

od swings may occur at any point in treatment, even lower doses. Hallucinations and related experiences have noted only after repeated heavy doses. They have been also after 300 γ or higher doses, the lowest point at h continuous abreaction occurred was after a total of γ in three doses, following a break in treatment of weeks. Continuous abreaction has followed 1200 γ ree doses after a break of several weeks. The continu reaction may occur without preliminary and more brief ed reactions. In one case a further 1000 γ in three doses ed to establish a continuous reaction

1 case reactions continued for three weeks; treatment chlorpromazine was then started and it appeared to rol further reaction. It is important to bear in mind that patient's statement that reactions have ceased is not ble: they may begin again after an apparent return to al I could not at present put a limit to the time during h delayed reactions may appear

he factors which may affect delayed reactions ude:

1) *Interference* —Over-solicitous attention during the acute e upset 2 patients who could not let themselves go had reactions next day similar to those they would have , but they controlled these to some extent. In the light his experience it may be necessary to reconsider results ined by inquiry and tests during acute intoxication.

2) *Voluntary control.*—A patient apparently managed to n all reactions for five days after her last dose to prove she was fit to go home Others report that they can exert ited control after the acute intoxication is over in pany but must let go later *Hallucinations are often* whelming; they can be prevented to some extent by occupations but recur in intervals of relaxation and so fere with sleep

3) *Dosage.*—2 patients who had continuous reactions had onged treatment with doses of 200–400 γ over several s. The total doses were 4200 γ and 1000 γ respectively both had a break of three or more weeks during treatment

n the management of delayed reactions heavy seda n with barbiturates proved useless for stopping the ces though it appeared to 'cushion' some of the periences. This was possibly due to these patients ing previously had prolonged barbiturate narcosis d also barbiturates as sedatives at other times

Paraldehyde (5 ml intramuscularly) gave some sleep but it was inadequate alone or with bromide Methylpentynol ("Oblivon") gave rather better results with bromide Potassium bromide (gr 20 t.d.s) appeared useful as a basic sedative The best results were obtained with chlorpromazine (50 mg intramuscularly) (a personal communication from Dr Sandison suggested this, since chlorpromazine reverses electro-encephalogram changes due to LSD) We have not yet been able to demonstrate this effect in the E.E.G., but we are not yet sure that E.E.G. changes persist in the delayed continuous reaction

It may be useful to summarise the possible dangers

(1) In mood swings the dangers of depression are obvious; and euphoria may be also embarrassing

(2) Time and space distortion are an obvious danger in traffic.

(3) Hallucinations are perilous out of doors and socially embarrassing

(4) Insomnia is a great difficulty; reactions are particularly likely to occur when relaxing for sleep

(5) Impulsive behaviour, wandering and absentmindedness may all create difficulty

Rainhill Hospital,
near Liverpool

H ASTLEY COOPER.

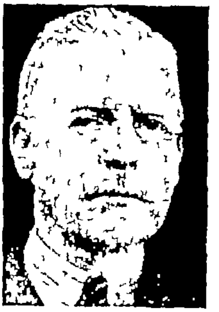
Obituary

HARRY JAMES RAE

M.C. M.A M.B Aberd D.P.H

Dr Rae who was formerly medical officer of health of the city and counties of Aberdeen and Kincardine died in his home in Aberdeen on May 7 at the age of 69

He was born in Woodside Aberdeen and he graduated M.A. from the University of Aberdeen in 1907, and M.B with honours four years later After graduation he was appointed resident to Mr John Scott Riddell at the Aberdeen Royal Infirmary and the help and guidance he gave to the students on his ward is still remembered He took the D.P.H in 1914 but before he was fairly launched on a public health career he joined the R.A.M.C For his work with a field ambulance in Palestine he was awarded the military cross and was mentioned in despatches



After he was demobilised he resumed his work as tuberculosis officer in Aberdeenshire later succeeding Dr Watt as county M.O.H In 1929 he was appointed medical officer of health of the City of Aberdeen in succession to John Parlane Kinloch who had been appointed chief medical officer to the Department of Health for Scotland In 1930 Rae became medical officer also of the county of Kincardine He was also part-time lecturer in public health at the University of Aberdeen a post which medical officers of health of the city have always held

Thanks to his organising ability and foresight all the first aid posts were ready in these north-east towns before the outbreak of war in 1939 and his organisation never broke down during the eighteen months of heavy raiding in 1939–41

When the Royal Family were spending their annual holiday on Deeside in 1941 he supervised the immunisation against diphtheria of Princess Elizabeth and Princess Margaret He was made an honorary physician to King George VI and later to the Queen

After his retirement in 1952 he found time and interest for fresh responsibilities. For the past two years he had been visitor and inspector in public health and social medicine to the universities and medical schools for the General Medical Council. He was also a past president of the Royal Sanitary Association of Scotland and a member of the town council of Aberdeen

A U W writes The medical practitioners in the north east of Scotland—especially those of the older groups—were saddened by the death of Dr H J Rae

His end marks the passing of a great era—the days of the medical officers of health who were administrators, clinicians, and advisory consultants in all matters relating to public health Though always fully and busily engaged in high undertakings, he 'never despised the day of small things', and his kindness and ready help, always so quickly and so courteously given to the country general practitioners, were significant of the true nobility of his character"

Dr Rae is survived by his wife, two sons, and two daughters One of his sons is Dr W J W Rae of Aberdeen, and a daughter is Dr Isobel Margetts of Nottingham

JOHN LOWE

C B E, M C, M D Birm, F R C P

Dr Lowe was medical secretary of the British Empire Leprosy Relief Association for just over a year, but he brought to his appointment many years of clinical experience in India and Africa His death on May 13, at the age of 57, is a loss to the campaign against leprosy

He was born in 1898, and he went straight from King Edward's School, Birmingham, into the Army to serve in France throughout the first world war He rose to the rank of captain in the King's Own Lancaster Regiment and won the M C He returned to study medicine at Birmingham University and graduated M B in 1922 The next year he went to India as a Methodist medical missionary to the leprosarium at Ditchpali in the Nizam's dominions There he also studied malaria, on which he later wrote the thesis which gained him the M D in 1937

In 1932 Lowe joined the research staff of the Calcutta School of Tropical Medicine, and three years later when Muir retired he succeeded him as head of the leprosy department In 1943 he was appointed to the chair of tropical medicine at the school, but in this post he still maintained his interest in the leprosy department

The previous year he had been appointed assistant editor of the *Indian Medical Gazette*, and in 1943 he succeeded Dr Everard Napier as editor The introduction of the sulphone drugs led him to return to clinical work, this time in Africa On leaving India in 1947 he was awarded the Kaiser-i-Hind gold medal, and the same year he took the M R C P For the next six years he was in charge of the research unit of the leprosy settlement at Uzuakoli in Nigeria The pioneer work which he did there on the essential action of the basic substance, dapsone, was of the greatest practical importance When he retired in 1954 he was appointed C B.E and elected F R C P On his return to this country he took over the medical secretaryship of B E L R A. and the editorship of the *Leprosy Review*

L E N recalls that his first association with Lowe was through a paper submitted for publication "This paper, which was on pellagra among leprosy patients in an institution in the Deccan where he was at that time working, showed him to be an astute observer and a clear thinker, this first impression was confirmed constantly throughout my association with him As an editorial colleague, he was most refreshing, his fearless criticism gave one great confidence, for one knew that one would not be allowed to get away with little unorthodoxies if he considered them beyond the pale of respectable medical writing He himself was a facile and clear writer

"Perhaps his most outstanding characteristic was that he was a great debunker, but he was always careful how he did his debunking Though a good Christian and closely associated with the missionary movement in India for many years, he never allowed his zeal to cloud his judgment In his early days he confided in me that he did not believe that the antileprotics then in use had the slightest direct effect on the course of the disease, but, though he desisted from joining the chorus of praise at that time showered on these ineffective drugs, he withheld his active criticism, he knew that faith in these drugs was the corner-stone of leprosy work throughout the world, and that to shake it publicly would do untold harm, not only to hundreds of thousands of leprous patients, but to the whole movement When he took over from me as professor of tropical medicine, he was, I know, thankful to get some respite from this work and the conflict that it must have engendered within him. Later, with the advent and development of the sul he saw new hope and readily returned to wh work on leprosy with—one should add—cons effect, it gave him further opportunity for deb into which this time he could put his whole heart."

P M-B writes "Lowe was a stocky, solid, r man holding strong convictions His rather personality was an outward mask and concealed a of great worth and determination His outstandin age was shown when once he was stricken dow paralysis during one of his periods of leave from and had for some time to live in an iron lung Fu his determination carried him through and he complete recovery He was one of those good C who devoted their lives to the study of leprosy, making any great outward show about it—and, he will long be remembered for the good original that he had done to alleviate this disease. It wa who made the assessment of the long term with D D S possible, it was he, with Dharme standardised the antigen for the Mitsuda reacti put it on a rational basis for diagnosis it was enthusiastically took up the question of B C G into the study of leprosy and indicated its prophylactic action Indeed all Lowe's writin there were many, were of a high order and much solid material"

Dr Lowe leaves a widow and two sons, both of are doctors

CLAUD FRANCIS FOTHERGILL

M A., M B Camb

Dr Fothergill, who died on May 6, at his Chorley Wood, was well known as doctor, chur and Alpine climber

He was born in 1878 at Tunbridge Wells and he st medicine at Emmanuel College, Cambridge, and Hospital After qualifying in 1906 he was acc a candidate by the Church Missionary Society, accident, while operating, led to septicæmia and ill kept him in this country In 1907 he settled in in Chorley Wood His interest in neurology and p logy was fostered by his experience in the 1914-18 and he became a consultant for shell-shock cases Ministry of Pensions For a year he was also in of the neurological department at Guy's and he was in charge of a psychological clinic of the M of Pensions and neurologist to the Ministry's appeal board He also had a private consulting

Outside his medical interests he gave much time energy to the Camps and Tours Union, and he hi led nine parties to the Holy Land He also extensive tours in this country to lecture to schoo churches on these visits He was an enthusiastic taineer, a member of the Alpine Club, and a vice-p of the Association of British Members of the Alpine Club, and he led many of the moun tours of the union, especially to Switzerland

C M-D, who will always be *grateful* to Foth for introducing him to Switzerland, writes "Foth was a *first-rate climber, so much so* that I doubt wh there is any major peak in the Alps that he has ascended When climbing he always wore a stiff even on the most severe ascents maintaining that kept him cooler and gave ventilation to his neck matter how exhausted any climber might be, Foth always forbade alcohol as a stimulant, for he found sugar was more effective and more prolonged in action My outstanding memory of him was the his practical Christian and evangelical faith. never was a more fervent or zealous preacher of gospel His message was always from the Bible like Billy Graham in this generation, whenever he at a meeting the substance of his address was Bible says' The private parties that he took to Sw land always ended each day with prayers and an ad more often than not by Fothergill himself

"The last time I met him was immediately after war, when we had been denied our annual visits Switzerland for so many years We each took a party out the moment Continental travel was perm and we shared the booking of a special train. On t on he was just the same Fothergill as I knew y five years before—a trifle older perhaps but wise exactly the same—even to the stiff collar'

1908 Dr Fothergill married Enid Annesley daughter late General John Gell She survives him with sons and a daughter

ETHEL CASSIE
O.B.E. M.D Edin. D.P.H

HOUGH an outstanding administrator Dr Ethel e did not have a bureaucratic mind, and her achieves in the Birmingham maternity and child welfare rtment were the result of an imaginative vision ined with a deep and genuine sympathy for the lems of the working-class mothers and an under ding of their needs

e was born in 1882 and graduated M.B in the ersity of Edinburgh in 1906 Her interest in social preventive medicine was early aroused and the wing year she took the D.P.H Later she became al officer of health for the county burghs of Clack annshire In 1921 she was appointed assistant ical officer of health for maternity and child welfare Birmingham.

ith the sympathy and support of her chief, Sir John rtson, she began her pioneer work. During the next ty years 25 welfare centres were opened 13 of them pecially constructed model buildings A babies ital with some 90 beds and a convalescent home for hers and babies were also opened Her book on *ernity and Child Welfare* was published in 1920 ing a visit to the United States she made a study of ature babies which led in 1930 to the opening in ingham of a ward for premature babies—now known the Sorrento unit. In 1935 she introduced the ingham foster mother scheme the first of its kind his country In the early years of the late war she ed 80 day nurseries and 6 residential nurseries for children of war-workers. For her services to maternity child welfare she was appointed O.B.E.

colleague writes 'At the time of Dr Cassie's ointment to Birmingham the health visitors were teer workers who shared her enthusiasm and wholetedly devoted themselves to carrying out her idea t the welfare centres should be places where mother child would not only receive advice and health ation but feel happy and at home. There was much the artist in her nature and she insisted that the tres should not only be useful, but beautiful, a fact ch the mothers appreciated It was a source of regret her that with the growth of her department, her ministrative work increased so much that she was iged to give up her clinical work and lose the personal tact with mothers and children which she so greatly ned But she never lost her interest in clinical medi e; it was perhaps her ability to see disease as a duct of environment which turned what might have n an outstanding physician towards preventive dicine She leaves behind a memorable record of vice to women and children'

r Cassie retired in 1948 owing to ill health, and she d on May 6 at her country home in Oxfordshire

Appointments

ITLE I R, M.A Camb, M.R.C.S., D.M.R.E consultant radiologist, Plymouth clinical area

Notes and News

SOCIAL CLUBS FOR EPILEPTICS

MANY epileptics, capable of leading normal lives are shy of mixing with people because they have for so long met with public prejudice To help them the British Epilepsy Association is starting a chain of social clubs Four clubs have already been opened in London and there are also clubs in Birmingham, Salford and Sheffield

The South London Social Club (54 Ormiston Road West combe Park, S.E 10) is open every Monday from 6 30 P.M until 10 P.M to men and women of all ages. Indoor games vary from cards to billiards refreshments are served free save for a voluntary collection and there is no entrance fee or subscription. The other clubs in London are the North London Social Club L.C.C Welfare Centre Corsica Street Highbury N the Chelsea Club King's Mead Sydney Street Chelsea; the Bethnal Green Social Club Eastbourne House Youth Centre Bullards Place E.2

The clubs are growing steadily but they need the support of epileptics and their friends. Further particulars may be had from the association 136 George Street, London, W 1

PRE-WAR DIETS

A REPORT lately published[1] records the details of the diets of 1352 families in the United Kingdom in the years 1937–39 Only those families with children were selected for study; but they were representative of the economic conditions of the time and the results are analysed for six different economic groups classified on average expenditure on food per head per week. The survey was planned by Lord Boyd Orr and it confirms and strengthens the conclusions set out in his book *Food Health and Income*, published in 1936 A preliminary report of the findings was available early in the war

In a preface, Lord Woolton our war time Minister of Food pays tribute to the work of Boyd Orr and his colleagues in providing essential information on which the food policy of the country was based The report, he says is "a unique record unique because it profoundly affected the life of a nation during a world conflagration. Fifteen years on, the report is necessarily mainly of historical interest In 45 well-set-out tables there are records of the foods consumed analyses of the diets in terms of nutrients and heights weights, cristal heights and hæmoglobin levels of the children. There are also details of the incidence of certain clinical conditions amongst the children such as chronic upper respiratory catarrh, knock knee skeletal deformities, otitis media, pyogenic infections and bronchitis.

University of Birmingham

Dr A. G W Whitfield has been appointed chairman of the board of graduate studies from Oct 1

University of Dublin

On May 12 the following degrees were conferred:

M.D—Margaret K B Knox F du P Meiring

M B B Ch B A O—P R D Black Jean R. Ellis A C A Hempel

Royal College of Physicians of London

On Tuesday June 21 at 5 P.M at the college, Pall Mall East, S W 1 Dr K M A Perry will give the Ernestine Henry lecture on Pulmonary Disease associated with Metallic Oxides.

Royal College of Surgeons of Edinburgh

At a meeting of the college held on May 11 with Prof Walter Mercer the president in the chair the following were admitted to the fellowship:

L I Burt Priya Brata Chakravarti D L Cornish Michael Dinner W G de Haas Sin Yang Fang I C Grayson A A Gunn T B Hogarth Michael Katzen Myron Lange J A MacDougall T J McNair Maung Kyaw Maung I G Nairn R L Plowman A F Richardson E H Rosenberg F J Sanders S R Shar Jack Stevens T J Thwaite J B Walker

Society for Endocrinology

On Tuesday May 24 at 5 P.M., at 1 Wimpole Street, London W 1 Dr A Lacassagne (Paris) will give a lecture on Endocrine Factors concerned in the Genesis of Experimental Mammary Carcinoma.

Royal College of Surgeons of England

At a meeting of the college on May 12, with Sir Harry Platt, the president, in the chair, the following were admitted as elected fellows Dr R D Langdale Kelham (Roehampton), Dr L S Debenham (Scarborough), Prof J McCunn (Royal Veterinary College) and Dr Gwen Hilton (University College Hospital)

Dr L C Thomson was appointed as the first Edridge Green lecturer, and Prof Geoffrey Hadfield and Dr Leslie Foulds were appointed as *Imperial Cancer Research Fund* lecturers Dr J M French was awarded a Mackenzie Mackinnon research fellowship The Begley prize was awarded to Malcolm Swann

Licences to practise were conferred on the candidates named in the report of a comitia of the Royal College of Physicians (*Lancet*, May 7, 1955, p 978) and on N A Waring, who have passed the final examination of the conjoint board A diploma in child health was awarded to the candidate named in the same report

Diplomas of fellowship in the faculty of anæsthetists were granted to the following

P J Horsey M D Mehta, France Brun, A V Jenkins William Brooks Betty R Warltier, W R Lamb P D Kempthorne B L Day G G Harrison A G MacKinnon H P Penn, D B Scott L M V Attygalle, G W Black Peter Hall A M Reid, Peter Stuart, I D Campbell, Brenda M Dempsey, Margaret M Fitzgerald, P J Roffey Rosemary A Fraser

Tribute to Professor Vining

On May 6, in the children's ward of the Dewsbury General Hospital, members of the consultant and nursing staff and local general practitioners entertained Prof C W Vining when a plaque was unveiled to commemorate his work as pædiatrician to hospitals in the district from 1930 to 1953

London Amateur Boxing Association

A meeting of the medical officers of this association is to be held at 69, Victoria Street, London, S W 1, on Tuesday, May 24, at 8 P M, when Mr A Rugg Gunn will speak on eye injuries The meeting is open to all doctors.

World Health Assembly

The eighth World Health Assembly opened in Mexico City on May 10 Dr Ignacio Morones Prieto, minister of health and welfare of the government of Mexico, was elected president, and Dr S Al Wahbi (Iraq), Dr J Gratzer (Austria), and Sir Arcot Mudaliar (India) were elected vice presidents

Grants for Research on Leukæmia

The Robert Roesler de Villiers Foundation of New York will shortly make grants in aid (maximum about £350) in support of research on leukæmia Investigators in the United Kingdom should apply to the regius professor of physic, University Department of Medicine, Tennis Court Road, Cambridge, before June 15

Secondary School for Spastics

The National Spastics Society has opened a secondary school for spastics at Dene Park, Tonbridge, Kent The school, which will be known as the Thomas Delarue School, will take 18 children this term, and it is hoped eventually to accommodate 45 handicapped boys and girls Education up to general certificate level, combined with treatment, will be provided A second school will be opened on May 11 in Cardiff The society hopes to open three more schools this year Further information may be had from Mr C Pritchard, National Spastics Society, 28, Fitzroy Square, London, W 1

Harveian Society of London

The society's Buckston Browne Gray Hill dinner at the Royal College of Surgeons on May 13 was a medicolegal occasion Sir Fred Pritchard, Q C, proposing The Society, hoped for closer ties between the two professions, and he looked forward to the time when this friendly coöperation would make a substantial contribution to improving the lot of the people for whom *laws were made* He referred especially to the rules about the law of insanity which had held good (or bad, many would say) for so long, and which would continue to do so unless the two professions got together to change them. In his reply, Mr A Dickson Wright, the society's president reinforced Sir Fred's call for a more effective liaison between Medicine and the Law, and later Mr H Edmund Davies, Q C, added his counsel in support of the case Mr Davies was replying to a warm welcome extended to The Guests by Dr D Geraint James

Mental Hospital as a Therapeutic Community

A weekend course on this subject for psychiatrists, hospital nurses, education officers, social workers, oc therapists, and mental hospital staff will be held at P Manor Residential College, Burton, Wirral, Cheshire, June 3 to 5 Further particulars may be had from Dr Frost, Deva Hospital, Liverpool Road, Chester

ORPROMAZINE (Largactil Thorazine, Mega) has been used in psychiatry since 1952 and it becoming possible to assess its position in relation er psychiatric treatments

Chemical and Pharmacological Properties

some time it has been known that the anti aine drugs have multiple pharmacological properties s their main action; for example some have ine-like properties some atropine like while yet have the actions of quinidine or pethidine All substances show in various degrees anti-adrenaline, cetylcholine, and anti histamine activity (Burn utta 1948) In addition, some of the anti histamine , such as diphenhydramine (Benadryl) and ethazine ('Phenergan') have a sedative action cing drowsiness and sleep after an initial period of ria. Chemically chlorpromazine is closely related e anti histamine drug promethazine and to the arkinsonism drug ethopropazine hydrochloride ivane')

chemical and pharmacological properties have been bed in detail by Courvoisier *et al* (1953) and eo (1954)

appears to be rapidly absorbed from the intestine the oral and intravenous doses required to produce toms of toxicity *are about equal* with *similar time* als from administration to the onset of symptoms action is maximal at one hour with appreciable s at six hours *and some activity* at twenty four . Since only 7% of the doses administered is ted in the urine in three days most of the drug is mably metabolised in the body though the route known

lorpromazine has a sedative action and under its nce the patient appears dreamy calm listless or otic and may *complain of cold* muscular weakness thirst (Dundee 1954) The blood pressure is labile ally induced vomiting is inhibited and the central n of alcohol barbiturates anæsthetic agents, and esics is potentiated (Beard 1954) The sleep activity n by electro-encephalography when these drugs used is like that of physiological sleep and quite e that seen with *barbiturate induced sleep* (Terzian)

ntal conditions reported to have been treated sfully with chlorpromazine include mania, hypo a, and psychomotor excitement (Lehmann and ahan 1954) confusional states (Delay et al. 1952a b Martin 1954) acute and chronic alcoholism rt et al 1954 Cummins and Friend 1954) *agitated* ssion, melancholia chronic hallucinatory psychosis etable in omnia and intractable pain and neuralgia ald and Bouttier 1953) and various neuroses kelman 1951 Sigwald and Bouttier 1953 Azima Ogle 1954 Garmany et al 1954)

6874

The clinical effect, which apparently enables the drug to benefit so many different conditions seems to consist in a reduction of tension, a loss of preoccupation and a reduction in psychomotor activity (Elkes and Elkes 1954) Manic states have been said to be particularly susceptible to the action of chlorpromazine (Lehmann and Hanrahan 1954 Martin 1954 Cossa et al 1953) Elkes and Elkes (1954) in a small controlled series found it of particular benefit in reducing the overactivity and *agitation of chronic psychotic patients* Several workers have applied this with benefit to similarly excited and overactive schizophrenics (Staehelin and Kielholtz 1953 Arnold et al 1953) This beneficial effect is especially evident in chronic cases considered incurable but only where the underlying personality has not been damaged (Sal y Rosas et al. 1954) Chlorpromazine influences particular groups of symptoms and cuts across diagnostic categories, an effect seen in other forms of physical therapy used in psychiatry—e g., prefrontal leucotomy

We *report here the effect of the drug on 224 female* patients in Bexley Mental Hospital. They formed a consecutive series and include 24 cases with controls A small group of 23 male patients was similarly observed and the results (not presented) differed in no way from those obtained in the females.

Material and Methods

Group A comprised 200 patients placed consecutively on treatment with chlorpromazine This group contained psychotic and some neurotic *patients and* was *typical* of the patients under treatment in the hospital Treatment was initiated by the doctor concerned with each case, but subsequent assessment was made by the *investigators in the following* manner Patients who showed a favourable response were placed on placebo tablets identical in appearance with the chlorpromazine *tablets, for a month* and the effect was noted Then either the active tablets were administered again or if improvement was still *maintained* the treatment was discontinued

Group B comprised 48 patients selected for treatment largely because they were restless agitated and showed psychomotor excitement In this respect they *formed* a sample of the most chronic and *intractable* the hospital patients and were unpromising from the therapeutic point of view By random selection 24 of these were started on chlorpromazine and 24 *on* the placebo the hospital pharmacist alone knowing which patients were receiving chlorpromazine and which the placebo

Methods of Administration

Chlorpromazine was given either by intramuscular injection followed by oral administration of tablets or by the oral route alone With the former method up to 150 mg daily usually in three *doses, was injected for* four days. No special precautions about rest in bed were taken, but the nurses were made aware *of the* possibility of faintness after *injections* and told to rest the patients if this appeared necessary Owing to the low pH the solution is irritant to the tissues (*Cloutier* 1953) but in practice if the chlorpromazine is given by deep intramuscular injection few patients complain of soreness, though indurated areas are produced in some and may persist In 1 case out of 33 thus treated a cold abscess formed

Many workers have commented on the more potent effect of parenteral administration—e g *Martin (1954)* and Charatan (1954) In the present series of 33 patients started on injections and then treated by oral *administra*tion 13 were either symptom free or much improved *The corresponding figure for purely oral* administration is 43 symptom free or *much improved* out of 167 treated This is no more than suggestive that the parenteral route may be the more potent

In some patients the curious phenomenon was observed that, though they did not respond to initial oral administration, an effect produced by parenteral administration could be maintained by an oral dose

The dosage by mouth was started at 75 or 150 mg daily in three doses, and varied, according to the response, up to 450 mg daily. Most of the patients received 150–200 mg of the drug daily

Results

GROUP A

This group consisted of 200 female inpatients selected only because they were consecutively placed on treatment with chlorpromazine This was instituted by a number of different doctors for a variety of conditions

Table I shows that of the 200 cases 124 (62%) improved, 56 (28%) becoming much improved or symptom-free, and 76 (38%) remained unimproved This assessment was made on the most stringent grounds and is of more value when it is appreciated that the majority of these patients were chronic hospital patients (Affective states mean age 53, mean duration of stay in hospital 3 8 years Miscellaneous states mean age 45, mean duration of stay 1 6 years Schizophrenic states mean age 42, mean duration of stay 10 3 years)

TABLE I—RESULTS OF CHLORPROMAZINE IN 200 CONSECUTIVE CASES

Diagnosis	Changes in symptoms				Total
	No change	Improved	Much improved	Symptom free	
Schizophrenic states	31	44	26	2	103
Affective states	36	19	18	7	80
Miscellaneous states	9	5	3	0	17
	76	68	47	9	200

Schizophrenic Group

Although examples of all types of schizophrenia were included, the great majority of the patients in this group were catatonic or paranoid schizophrenics showing some of the symptoms of excitement, aggressiveness, overactivity, noisiness, and hallucinations 72 (70%) showed some improvement, and 26 of these were greatly improved, 2 being rendered symptom-free Apart from certain cases of mania (mentioned below) the most dramatic responses to chlorpromazine were in this group

To obtain a clearer picture of the nature of the response 25 of this group were selected for closer examination These patients had shown the greatest degree of improvement and were rated as regards their main before and after treatment (table II)

TABLE III—EFFECT OF CHLORPROMAZINE IN 80 CASES AFFECTIVE DISORDER

Diagnosis	Changes in symptoms			
	No change	Improved	Much improved	Symptom free
Simple depression	5	7	6	3
Agitated depression	2	4	2	3
Depression with hypochondriasis	7	1	0	0
Neurotic depression	13	5	3	1
Depression with major organic disease	2	1	1	0
Mania	7	1	6	0

The symptoms most often improved were ness 17/17, noisiness 15/15, overactivity 13/13, ag 6/6, tension 5/5, depression 4/4, incontinence, incapability of occupation 15/16, disturbed sleep and disturbed appetite 9/10 The mean age was 43 the average duration of stay in hospital 12 8 Generally speaking chlorpromazine controlled p motor excitement and agitation, aggressiveness, tension, and allowed better rapport, enabling the to become occupied and resocialised On the hand, the basic schizophrenic symptoms—thought turbance, delusions, and hallucinations—appeared much less influenced, and continued, though fre reduced in intensity, even though the general and other individual symptoms had much im Other authors have commented on the use of promazine for insomnia, either alone or as a of other sedatives, and in our group of disturbed ch patients less night sedation was necessary while were on chlorpromazine therapy

In this group all the patients relapsed sooner or usually in from one to three weeks after the su of a placebo, and none maintained their improvement more than three months after chlorpromazine had withheld

The most important feature in the action of promazine on the chronic schizophrenic is the ment in his ability to enter into activities p impossible This is of immense benefit and can rap lead to a complete change in the character of a chr ward It is comparable to the remarkable effects duced in suitable cases by maintenance electroconv therapy (E C T) (Moore 1943, Shoor and Adams 195

Some chronic schizophrenic patients had been rece chlorpromazine for more than a year but relapsed w a few weeks of discontinuing treatment How great their improvement, with 2 possible excep

X̲ symptom much improved O new and unwanted symptom S, symptom present but unchanged ioned below, careful examination always revealed the patient still had disordered thought processes ugh able to ignore them No basic qualitative go took place in the underlying schizophrenic ess.

e 2 schizophrenic patients classed as clinically tom free are of particular interest in this connection following case typifies both.

woman aged 32, was admitted to hospital in 1949 led manneristic, and hallucinated; but there was a uating affective element in her illness, and when at her she was able to leave the hospital to visit relations for ends. During the last four years she had become increas deluded, hallucinated, and aggressive; much of her h was crudely sexual and there were phases of catatonic ement. She improved temporarily with courses of E C T, over the years there was a steady deterioration in her viour On chlorpromazine 200 mg daily by mouth for months she made an apparently complete recovery admitted to having been deluded saying that her thoughts eemed outside her control. Yet she gave the impression all was not quite well. Occasionally there was a suggestion her thoughts were oblique and her mood inappropriate remained well for ten weeks without chlorpromazine ng the hospital whenever she wished for shopping and to her home She was then sent home on trial but sed acutely within a few weeks. On further chlorpro ine by mouth she showed no improvement, but she onded to intramuscular chlorpromazine given for three

dive Group

his group consisted of 80 patients of whom 44 showed lominantly depressive symptoms and 14 manic

LE IV—RESULTS OF CHLORPROMAZINE IN 39 PATIENTS HAD NOT IMPROVED OR HAD RELAPSED AFTER E.C.T

ponded but peatedly re psed	4	2	9	5	20

atement 22 were considered to be predominantly rotic, and the affective disturbance was secondary environmental and other social difficulties

Table III shows that chlorpromazine was moderately cessful in controlling symptoms in simple retarded in agitated depression but had very little effect in ochondriacal depressive states and gave no very ouraging results with neurotic depressions This also our experience in treating neurotic depression outpatient clinics In contrast to Garmany et al 54) we have not found chlorpromazine of any nificant value in states of anxiety or neurotic tension in phobic or obsessional states For example of 11 s of acute anxiety states 8 showed no improvement 3 very little Nearly all our evidence however derived from outpatients not reported here in detail 0 of whom were given chlorpromazine parenterally s finding is supported by Martin (1954) and Sigwald 53) Martin (1954) comments also that patients with e conditions are often alarmed by the sensations duced by the chlorpromazine some even becoming siderably worse In view of these observations the iscriminate use of chlorpromazine in neurotic states contra indicated

Manic symptoms either responded very well or were npletely refractory and all good reactions occurred early as the first week or so A similar situation has en been observed on treating manic states with E C T., treatment being useless or even aggravating the ndition on some occasions, though producing dramatic issions on others

TABLE V—RESULTS OF CHLORPROMAZINE IN 17 MISCELLANEOUS CONDITIONS

Diagnosis	Changes in symptoms				Total
	No change	Improved	Much improved	Symptom free	
Aggressive psychopaths defectives, epileptics	4	2	0	0	6
Carcinoma pain	1	0	0	0	1
Mastectomy with mania	0	1	0	0	1
Overactive senile and presenile dementias	2	1	2	0	5
Huntington's chorea (3) undiagnosed dyskinesia (1)	[illegible]	1	1	0	4

The response to chlorpromazine by depressed patients who had not improved with E C T or had repeatedly relapsed is of considerable interest (table IV)

It will be seen that patients who had failed to respond to E C T did equally badly when treated with chlorpromazine but those who had responded to E C.T and had pursued a relapsing course did on the whole remarkably well

How long to continue the administration of chlorpromazine in depressive states is not easy to answer Some patients appear to be kept going by its use until a natural remission occurs, but most of them relapse when it is discontinued, and this particularly applied to those who relapsed on the discontinuation of E C T and were maintained by the administration of chlorpromazine

Depressed patients in whom agitation was predominant and who received chlorpromazine alone showed only a partial response similar to that seen in schizophrenic states, suggesting that the agitation and restlessness had merely been masked. In depressive or manic illness the drug is clearly no substitute for convulsion therapy but it is a useful adjunct in the initial stages when the patient is overactive and unmanageable

Miscellaneous Group

This group contains the least successful of the patients treated. The numbers in each section are, however, too small for statistical assessment (table V)

The poor effect of chlorpromazine on aggressive psychopaths, defectives, and epileptics is as might be expected, more akin to our results in neurotic tension states than in psychotic aggressiveness and tension

Benefit from chlorpromazine has been reported in a case of Huntington's chorea (Azima and Ogle 1954) Only 1 of our patients with this condition showed a slight diminution in the intensity of her movements and her mental state remained unchanged; but the patient with undiagnosed dyskinesia, possibly a case of torsion dystonia was much improved The movements were well controlled by chlorpromazine and reappeared on the substitution of a placebo

GROUP B

As already mentioned this group comprised 48 female inpatients showing motor restlessness, psychomotor agitation and excitement who were by random selection

TABLE VI—RESULTS OF TREATING 24 OVERACTIVE PATIENTS WITH CHLORPROMAZINE TABLETS AND 24 SIMILAR PATIENTS WITH PLACEBO TABLETS

—	Changes in symptoms				Total
	No change	Improved	Much improved	Symptom-free	
24 patients given chlorpromazine	8	13	1	0	24
24 patients given placebo	19	5	0	0	24

given either chlorpromazine or placebo tablets Most of them were chronic patients of poor prognosis (mean duration of stay 9 6 years, mean age 43) The aim of this investigation was to determine whether chlorpromazine was effective enough to warrant continued assessment of the larger group, and, though the results obtained from this series of chronic cases might not be applicable to the group as a whole, we felt that a positive result would warrant a bigger investigation Table VI indicates that chlorpromazine proved highly effective in the control of agitation and excitement

These results show in the patients given chlorpromazine 8 failures and 16 improvements, and in the patients given a placebo 19 failures and 5 improvements These results are significant at the better than 1% level ($\chi^2 = 11$ 5, $P<0$ 01) indicating that the drug was responsible for the benefit, because the other conditions were standardised

Complications

Previous workers have commented on the high incidence of minor fainting attacks, headaches, vague cramps, dryness of the mouth, and transient pyrexia This was our experience also, these symptoms being so common that eventually they were not recorded After a few days' treatment the patient usually made no further complaint and treatment was continued satisfactorily

Of the 224 patients 22% developed sufficiently severe complications to stop treatment, but in 10 it was subsequently restarted without further complications Major symptoms occurring either alone or in combination were severe collapse (9), persistent pyrexia (8), persistent pains in the legs or in the abdomen (7), persistent rashes (4), gross confusion (4), severe headache (4), jaundice (3), vomiting (3), severe nausea (3), persistent tachycardia (3), constipation (3), convulsions (2), facial œdema (2), parotitis (2), severe cyanosis of the legs and trophic ulcers (2), marked depression (2), cardiac failure and œdema of the ankles (2), auricular fibrillation (1), diarrhœa (1) and hæmatemesis (1)

Some of these complications require a few words of comment The convulsions occurred in 2 epileptics who had not experienced seizures for several years and were not taking anticonvulsants regularly The mechanism of the effects on the periperal circulation and the heart is not clear and would repay further investigation No case of blood dyscrasia was noted in this series, in which the longest time of administration has been over fourteen months

2 patients developed cardiac enlargement with œdema of the ankles One had shown no clinical signs of heart-disease before treatment, and the condition returned to normal when chlorpromazine therapy was discontinued The other had had previous, though less severe, attacks of congestive failure Cardiac failure and enlargement occurred after eighteen and three weeks of treatment respectively, the drug being given by the oral route in both cases

Deaths have been reported (*British Medical Journal* 1954) in 2 cases of liver damage and jaundice, and Lehmann and Hanrahan (1954) found slight changes in the cephalin-cholesterol tests in about 50%, and jaundice in 4%, of their cases

In our series the jaundice (3 cases) disappeared within forty-eight hours of discontinuing chlorpromazine therapy, and no evidence of liver damage was found with standard liver-function tests, including flocculation tests

Martin (1954) reported troublesome constipation and diarrhœa In our series one case of persistent constipation occurred after sixteen weeks, and the case of severe diarrhœa after three weeks' treatment

The incidence of complications (22%) in this series leads us to conclude that chlorpromazine requires careful supervision, particularly when given to outpatients Complications do not usually occur with high dosage in patients who have been having the drug for some but they most commonly arise between the first third weeks of treatment in those who have just with doses of 75–150 mg a day Complications no more frequent in patients who had started intramuscular injections

Discussion and Conclusions

Whenever a new drug is introduced into medical ment, enthusiasm or scepticism tend to obscure merits, unless its benefits are decisively clear, as i case of penicillin therapy, It is usually some time its true merits can be assessed and it can be giv rightful place in the armamentarium of treatment

Chlorpromazine is clearly not a curative drug schizophrenia its benefits are purely sympto the underlying thought disorder and other symp being masked This failure to provide a cure in sc detracts from its value as a special "sedative" resocialising agent We already have precedent this in the benefits from standard leucotomy, and masking action of phenobarbitone and other convulsants in epilepsy Whether a patient who had his major symptoms masked in this way for a time will eventually be able to maintain his improve after chlorpromazine therapy has been disconti still remains to be seen We are tempted to suggest if the patient's disturbed mental state can be "re sufficiently, he may remain well

The precise mode of action of chlorpromazine is obscure pharmacologically, but clinical observ suggests that cortical function is little affected, excitatory states are diminished and inhibitory s increased Some observers have used the term "ch leucotomy" to describe these effects, but in our exper such a term is misleading In no case have we obs *Witzelsucht*, euphoria, or loss of spontaneity or inhi such as may be observed after leucotomy, nor hav seen the peculiar quality of post-leucotomy indiffere nor personality changes, a point of some import Those patients who have done well have shown rapport and some insight into their condition, in our view tends to distinguish them from some leucotomy patients

Chlorpromazine is of considerable value with ch patients in the large mental hospital ward Pat who are a continual source of disturbance may be quiet, cooperative, occupied, and able to leave the pital for short periods of leave Their relatives new interest in their welfare, and this is a further help in their social recovery With the most distu elements of the community judiciously elim in this way, the ward atmosphere improves, and patients also become settled, socially improved, and responsive in the quieter environment Since the duction of chlorpromazine for selected cases less has been required, and there has been a reductio just over half in the quantity of sedatives issued by night staff Improved patients have shown inc in weight of up to 2 st, and, as suggested by Elk Elkes (1954), this appears to be related to their imp appetite and eating habits

In summary, chlorpromazine is of limited use a adjunct to other forms of therapy, or where the contra-indicated, and should be considered in following clinical conditions

(1) All types of psychomotor overactivity or excit with or without confusion

(2) Aggressive, noisy, restless, chronically over behaviour, to effect some social restoration with hospital environment

(3) Acute mania or catatonic states of excitement, E C T or insulin coma therapy can be started. patients in this group will probably need no f treatment

he proviso must be made, however that the drug is ensive compared with the usual sedatives, and luces a fairly large proportion of toxic effects which render it unsuitable for lengthy *administration*. It ld be wise to supervise carefully its use in outpatient rtments and in general practice It is of use only in nited group of patients and even when they appear ble for treatment not all will respond for reasons h are not clear at present When they are responsive ever it provides a form of assistance which is ualled by any other drug in our possession

Summary

he effects of chlorpromazine in 224 recent and chronic otic and psychotic patients were studied.

lorpromazine effectively controls the symptoms of homotor overactivity aggressiveness, agitation and hotic tension and is particularly valuable in the ment of chronic overactive deteriorated schizo nics, mania, schizophrenic excitement and patients are unsuited for electroconvulsion therapy or relapse an initial improvement after it.

lorpromazine is not a substitute for electroconvulsion py or other forms of physical treatment where are indicated Judiciously applied it can entirely the atmosphere in wards where aggressive and ted patients are treated.

considerable number of toxic reactions are ntered during its administration.

lorpromazine is a valuable though limited addition e therapeutic armamentarium of the psychiatrist

r thanks are due to Dr W R Thrower of Messrs. May aker for supplying the placebo tablets the nurses doctors of Bexley Hospital for their assistance and B F Heap the pharmacist of the hospital for his ible help

Owing to modern conditions—lack of funds lack of and not least lack of suitable paid help—most mothers reed to look after their young children themselves. If hildren are born into an intelligent family the mother robably expect too much of them too soon—and where modern home will they find their childish refuge? by highly-strung super-sensitive difficult children he fashion while sleeping draughts and aspirin are a nonplace in the nursery Nannies are fast dying out but this is seemingly inevitable let us not therefore assume or our children are better off without these simple but people Self-expression sensible toys and lots of grated are all very well but there is more childish comfort to hand in a hand-dressed teddy and a milk pudding —LA M. L. CHANCE, *Observer*, May 22 1955 p 13

FOR many years the term "cœliac disease" was used to describe a disorder of childhood in which chronic diarrhœa steatorrhœa and malnutrition were presenting symptoms Until recently no precise definition of this disease was made and it was generally described by various signs and symptoms Steatorrhœa was recognised as one of the most constant findings but the steatorrhœa of cœliac disease was not clearly differentiated from that of pancreatic insufficiency until Andersen (1938) separated fibrocystic disease of the pancreas as a separate entity and showed that the steatorrhœa in fibrocystic disease resulted from deficiency of pancreatic lipase. This work led to subdivision of the cœliac syndrome into *cœliac disease and fibrocystic disease of the pancreas* Further progress in the ætiology of cœliac disease was achieved when Dicke (1950) and Weijers and van de Kamer (1950) demonstrated that children with cœliac disease recovered when wheat and rye flours were excluded from their diets Subsequently it was shown that the gluten fraction of wheat and of rye contained the harmful substance and that the starch fraction was harmless to these children (Anderson, Frazer French Gerrard Sammons and Smellie 1952 van de Kamer et al 1953) The fact that not every patient with chronic steatorrhœa and normal pancreatic function responds to a wheat gluten free diet has been stressed in previous reports—in children and adolescents who received treatment late in their illness (Gerrard Ross and Smellie 1955), and in adults with idiopathic steatorrhœa (Anderson Frazer French Hawkins Ross and Sammons 1954)

The purpose of the present study was to determine what proportion of children presenting with active cœliac disease responded to a diet free from wheat gluten (rye is not a common food in this country) and to examine the ætiology of the disorder in those children who did not respond

Materials and Methods

As steatorrhœa is generally accepted as the most constant finding in cœliac disease, the main criterion for inclusion in the present series was the presence of chronic steatorrhœa with normal pancreatic function Moreover it was thought that an assessment of steatorrhœa by fat balance studies afforded the most reliable single test of gastro intestinal function Steatorrhœa was defined as a mean daily fæcal fat of over 5·0 g this was found in 30 children with normal pancreatic function aged from 6 months to 10 years, who were admitted to Birmingham Children's Hospital during the years 1951 to 1954 A marked improvement in fat absorption was the main criterion of response to the diet.

The following investigations were carried out (*a*) before treatment with a wheat gluten free diet and (*b*) after a period of from three to twenty four months on the diet:

Fæcal fat—A fat balance was carried out on each child for ten days. The child received a known dietary fat intake and the fat content of the stools was estimated daily by the fatty acid method of van de Kamer et al (1949) The mean daily fæcal fat output by each child was then calculated

Systemic lipæmia was studied by means of the chylomicrograph technique (Frazer and Stewart 1939) after a meal containing 10–20 g of fat, depending on the age of the child The actual procedure used has been previously described (Ross 1955) The maximum chylomicron increment—i e, the greatest increase in fat particles per standard high-power field above the fasting level—was obtained for each patient In this study the counts were made by two of us whose counts roughly tallied three counts were made on each blood specimen and the average count obtained As there was considerable subjective deviation in any one count, we have placed the results of the maximum increments in four broad groups—under 50, 50–100, 101–150, and 150 and over To serve as controls, chylomicrographs were carried out in 24 children, between 6 months and 11 years of age, who were not suffering from any intestinal disorder

Weights were compared with the normal standards of Engelbach (1932) as adapted by Wilkins (1950), and for each child the percentage of the standard weight for age was calculated

Glucose tolerance—Oral glucose tests were carried out in some patients, the test was omitted in children who were apprehensive or nervous The dosage of glucose was 0 5 g per lb body weight, and the blood-levels were estimated by the method of Hagedorn-Jensen

Hæmatology—In all the children, the number of red cells, the hæmoglobin value, the packed-cell volume, the mean corpuscular volume, and the mean corpuscular hæmoglobin concentration were estimated

Radiography of small intestine—The presence of dilatation of the small intestine had previously been demonstrated by means of a non flocculating preparation of barium sulphate, both in active cœliac disease (Anderson, Astley, French, and Gerrard 1952) and in the later stages of the disease (Astley and Gerrard 1954) In the present study, therefore, particular attention was paid to the degree of dilatation of the small intestine, which was classified in four groups—gross, considerable, slight, and borderline

Pancreatic enzymes—The amylase, lipase, and trypsin activities of duodenal juice were estimated (before treatment only) by the methods described by Anderson, Frazer, et al (1952)

Results

Of the 30 children 28 responded to the diet, as evide by a considerable decrease in fæcal fat (table I). Be treatment with the diet, the mean daily fæcal fat ex by each child was 6 0 g or over, the mean value for 28 children was 9 3 g (S D ±2 97) After treatment periods ranging from four to twenty four months (7 1 months) the daily fæcal fat output by each chil fallen below 5 0 g, the mean value for the 28 chi was now 3 3 g (S D ±0 97)

In order to prove that wheat gluten was inde causative factor in the children who responded to diet, wheat gluten in a dosage of 10 g daily was give the recovery stage to 12 of these 28 children, developed steatorrhœa in two to four weeks, accomp by other signs and symptoms of deterioration deterioration was as great in the children who had on the gluten free diet for many months (longest p forty eight months) as in those who had received gluten-free diet for only a few months

CHILDREN RESPONDING TO THE DIET

Chylomicrograph—It will be seen from table II th maximum chylomicron increment above 100 par was found in 10 of the 28 children before treat compared with 20 out of 24 children after treat This difference is statistically significant (P=0·001) is in agreement with the previous chylomicro findings of Anderson, Frazer, et al (1952) Althoug chylomicrograph, before treatment, was depressed majority of the children in the present series, som counts similar to those obtained in the 24 "norma 22 of the "normals" had maximum increments ove

Weight—Before treatment, all the children below standard weight for age, the figures r between 48% and 99%, with a mean of 75% Trea resulted in a substantial increase in weight, the fi at the time of reassessment ranging from 68% to 1 with a mean of 92% 8 children were then over st

TABLE I—DETAILS OF INVESTIGATIONS (A) BEFORE AND (B) AFTER TREATMENT

Patient	Age (yr and month)		Period on wheat-gluten free diet (mos)	Mean fæcal fat (g per day)		Maximum chylomicron increment		Percentage weight for age		Glucose tolerance (maximum increment in mg per 100 ml)		Hæmoglobin (g per 100 ml)		Dilatation of small intestine

30	1 7	1 8	1	8 0	8·0	36	59	115 0	115 0	47		10 7	10 7	–

• + + + +, gross + + +, considerable + +, slight +, borderline –, nil ght for age The difference in the figures before and r treatment is highly significant (P<0·001)—a ing in keeping with that obtained in a series of dren treated late in the course of the disease (Gerrard, s and Smellie 1955)

lucose tolerance.—Table II shows that, of the 20 dren who had glucose tolerance tests before treat t only 2 showed an increment above 40 mg per ml (40 mg is the minimum increment usually pted as normal) compared with 8 out of 14 tests r treatment This difference is not statistically ficant, but the number of cases in this investigation small

ematology.—As we wished to find out if the anæmia ld improve with the diet alone the majority of the dren did not receive oral iron between the two assess its. Before treatment, the mean hæmoglobin value was per 100 ml the values were below 10 g in 13 of the hildren and the anæmia was always hypochromic. reassessment the mean hæmoglobin was 11 9 g and e of the children then had a value below 10 g hough the difference between the figures before and r treatment is statistically significant (P=0 001) the oglobin even after treatment was still below 13 g 0 of the children This suggests that treatment with diet alone was often insufficient to restore the hæmo in to normal—probably because body stores of iron e low Subsequent administration of oral iron lted in a rapid increase in hæmoglobin to normal es

adiography of small intestine.—Before treatment 26 ents received a barium meal examination, with a non ulating suspension of barium sulphate 24 of these wed slight considerable or gross dilatation of the ll intestine compared with 10 out of 22 examined r treatment This difference is statistically significant 0 001) These radiographic findings agree with those rted by Anderson et al (1952) and Astley and ard (1954)

onclusion.—In this group of 28 children who responded wheat gluten free diet as shown by a decrease in l fat the results of most of the other investigations wed a concomitant return to normal values Thus, e was a highly significant increase in standard weight age, and a significant rise in the maximum chylo ron increment and in the hæmoglobin level There also a significant diminution in dilatation of the ll intestine The increase in the maximum increment he glucose tolerance test was not however statistically ificant

CHILDREN NOT RESPONDING TO THE DIET

n 2 cases there was no decrease in fæcal fat

e of Bile-salt Deficiency

ase 29.—This girl was admitted for investigation when 3 s old Her mother stated that she had passed bulky ish stools since the age of 2 months and had had several cks of bronchitis. She was an active child with a good etite Table I shows that at this time she had a fæcal fat put of 17 5 g per day a flat chylomicrograph a percentage ght for age of 85 5 a normal glucose-tolerance test, a noglobin level of 12 5 g per 100 ml and considerable tation of the small intestine The duodenal juice contained pancreatic enzymes, amylase lipase and trypsin in mal amounts

he was treated with a wheat gluten free diet, but after teen months there was still no improvement in the torrhœa. She was then placed on a fat free diet and the content of her stools immediately fell to 3–4 g per day hich is within normal limits. This indicated that the fæcal was largely of dietary origin and that the steatorrhœa was related to the ingestion of wheat gluten

t 3½ years old her general condition was good, but the torrhœa was unchanged; the chylomicrograph was still even after an oral feed of emulsified olive oil buffered in n milk. Serum-cholesterol 105 mg per 100 ml (free 48 mg) serum bilirubin 0·2 mg per 100 ml bromsulphalein and thymol turbidity tests normal serum alkaline phosphatase 20 King Armstrong units

In view of the finding of steatorrhœa with normal pancreatic lipase and lack of response to a wheat-gluten free diet it was thought that this child might have a deficiency of bile salts. She was therefore given a preparation of bile Desibyl capsules gr 10 thrice daily half an hour before meals. Within a week her fæcal fat had fallen below 10 g per day and it remained between 4 g and 12 g daily while she received bile After six weeks the bile was discontinued and her fæcal fat output rose immediately to the original levels (see figure) Bile was recommenced and the child was discharged home. At the end of eleven months the bile was discontinued and she was given a low fat diet.

At the age of 7 she was readmitted to hospital for review having been six months on this low fat diet Her general condition remained good the chylomicrograph was still flat, even after emulsified olive oil. A barium meal with a non flocculating preparation of barium sulphate showed slight dilatation of the small intestine; when the examination was repeated with the same barium preparation with the addition of 10% butter there was no difference in the transit time. Serum-cholesterol 281 mg per 100 ml (free 185 mg)

TABLE II—RESULTS OF INVESTIGATIONS IN CHILDREN RESPONDING TO A WHEAT-GLUTEN FREE DIET (A) BEFORE AND (B) AFTER TREATMENT

FÆCAL FAT

Continuous fat balance in case 29, on 50 g fat daily, showing fall in fæcal fat on bile-salt therapy, followed by deterioration on withdrawal of bile salts.

On her last admission, in February, 1955, at 7½ years of age, an analysis of duodenal fluid gave the following findings alkaline phosphatase 54 K A units, cholesterol 6 5 mg per 100 ml (free 4 9 mg), Pettenkofer's reaction faintly positive The lipase activity of the fluid was determined by the method used by Anderson, Frazer, et al (1952), but two estimations were made, one with additional bile salts, as described, and one without additional bile salts The lipase activity was 2 6 units in the sample with additional bile salts compared with 1 3 units in the sample without additional bile salts, that is to say, the ratio of lipase activity in the estimations with and without bile salts was 2 1—approximately the same as that found in the duodenal juice of children without steatorrhœa

Two samples of duodenal juice were examined for cholic acid content by an adaptation of the method of Chabrole et al (1934) Table III shows that the cholic acid in these samples was respectively 0 21 mg per ml and 0 1 mg per ml—values were considerably below those obtained in specimens of duodenal fluid from 5 other children suffering from various disorders Blood serum analysis showed that cholesterol was still rather high (total 271 mg per 100 ml, free, 93 mg) The bilirubin content was 0 36 mg per 100 ml and the hæmoglobin 14 8 g

The disappearance of this child's steatorrhœa when she was on bile therapy, and the finding of a low cholic-acid content in her duodenal juice, suggest that her steatorrhœa was due to a deficiency of bile salts Despite the severe steatorrhœa, her nutrition was good, although a nitrogen balance was not carried out, it would seem that the defect in absorption mainly affected fat

Case of Fat Intolerance

Case 30.—This boy's birth-weight was 9 lb 6 oz, he was breast fed for five weeks and was then given National dried milk (half cream), and he was well until 2½ months old, when he had an attack of vomiting and diarrhœa which was diagnosed as gastro-enteritis Vomiting and diarrhœa persisted intermittently up to the time of his admission to Birmingham Children's Hospital at 4 months of age

At this time, he was marasmic (weight 8 lb 7 oz.) and so dehydrated that he required intravenous therapy No pathogens were isolated from his fæces When
valescent, he could tolerate only oral feeds
skim milk, he would vomit within half an
of receiving a feed of breast-milk, or Nat
dried milk, and subsequently had diarrhœa
could tolerate no more than 15 g. fat da
either as milk fat, margarine, or olive oil
on this dosage he had steatorrhœa his fæcal
ranging between 5 g and 9 g daily Bil
orally did not decrease the fæcal fat Estim
of amylase, lipase, and trypsin in duodenal
gave normal values He was discharged
hospital at the age of 14 months on Cow &
separated milk and a fat-free diet

TABLE III—CHOLIC ACID CONTENT OF DUODENAL JUICE

Patient	Age	Cholic acid (mg per ml)
Case 29	7 yr	(1) 0 21 (2) 0 1
Bronchitis	4 mos	2 4
Salmonella carrier	6 mos	3 1
Pancreatic fibrosis	6 mos	4 68
Bronchitis	2 yr	(1) 1 75 (2) 1 45
Cœliac disease	5 yr	(1) 1 4 (2) 1 3

When he was readmitted at 19 months of
his general condition was good (weight 2
4 oz) and he was able to tolerate 20 g fat d
but more than this provoked vomiting
diarrhœa Table I shows the results of inves
tions at this time In addition to the
micrograph after a standard fat meal,
micrographs were also carried out after
unemulsified and (*b*) emulsified olive oil,
rise in particle count was equally low in b
The serum-cholesterol was 657 mg
100 ml (free 44 2 mg)

On his last admission, at 2 years 9 months, his weight
30 lb He still had steatorrhœa and was still only ab
tolerate 20 g fat daily The serum cholesterol was 1
per 100 ml (free 81 5 mg) A barium meal was now ca
out (*a*) with fat and (*b*) without fat, using a non flocc
type of barium sulphate The examination with fat (
butter in the suspension) showed considerable gastric
with a residue in the stomach at seven hours, but no
twenty four hours, the barium in the small intestine
clumped into small aggregations, barium had reached
colon by four hours after the meal In the same examin
without fat, the stomach emptied normally, at one a
half hours, it contained only a little residue, the patt
the small intestine appeared normal The main diffe
between the examinations with and without fat was, the
the gastric inactivity in the examination with fat In a co
subject (a girl of 3 years in whom there was no reason
suspect gastric abnormality), the same amount of barium
mixture had left the stomach in two to three hours.

This child's symptoms seem to have originated from
attack of gastro enteritis in infancy The occurrence
vomiting after a meal containing a moderate amount
fat, together with radiological evidence of gastric st
in the barium meal containing fat, suggested that
administration of fat resulted in pylorospasm The c
of the steatorrhœa remains obscure

Discussion

28 out of 30 children with signs and symptoms of ac
cœliac disease recovered on a diet free from wheat glu
As they had all been ill for several months before tr
ment, their recovery on the diet is strong evidence
favour of the ætiological relationship of wheat gl
to their illness More precise evidence of this relation
was obtained by the reappearance of steatorrhœa
reintroduction of wheat gluten into the diet of 12 of th
28 children

2 of the children in the present series failed to resp
to the diet In their reinvestigation of 34 children
cœliac disease Gerrard et al (1955) likewise found 2
did not respond It therefore seems that, in a few ca
factors other than wheat gluten may be responsible
signs and symptoms of cœliac disease

In 1 of our 2 children the cause appeared to
deficiency of bile salts, and it is of interest that this
been proposed in the past as a possible cause of cœl
disease (Cheadle 1903, Miller 1920, Macrae and Mo
1931) Macrae and Morris demonstrated that in some ca
oral administration of bile salts improved fat absorption
either (they thought) because it made good a deficie
or because bile salts aided absorption of soaps. Th
present study suggests that a specific deficiency of b
salts may occasionally be responsible for steatorrhœa

n the other child who did not respond to the diet the ptoms of 'fat intolerance' dated from an attack gastro-enteritis A similar case also originating in tro-enteritis in infancy, is included in the series of rard et al. (1955) When last seen at 7 years old their d was still unable to tolerate fat if given 30 g fat y she had frequent vomiting with steatorrhœa In connection it is worth noting that after gastroentis the reintroduction of fat into an infant's feeds n needs to be gradual It would appear that these hildren had not regained their ability to assimilate

hough our findings show that various factors can give to the clinical picture of cœliac disease the vast nty of the children in our series—who had chronic torrhœa with normal pancreatic function—responded diet free from wheat gluten It now seems appro te to consider this disorder as a separate entity for h the term gluten induced cœliac disease' is gested.

Summary

f 30 children with active cœliac disease all but 2 onded to diets free from wheat gluten The main nostic criterion was chronic steatorrhœa with normal creatic function; and the main therapeutic criterion disappearance of the steatorrhœa

n the children who recovered on a wheat-gluten free improvement in fat absorption coincided with rovement in chylomicrograph standard weight for and hæmoglobin level, and with diminution in the dation of the small intestine but not with any ificant improvement in the glucose tolerance test

f the 2 children who did not respond to the diet 1 eared to have a deficiency of bile salts and the other d showed fat intolerance.

he term ' gluten induced cœliac disease is suggested the disorder in those children who recover on diets from wheat gluten

e wish to thank the consultant staff of the Children's pital Birmingham, for permission to study their patients, Sister N Howells and Sister J Woodward for invaluable with the metabolic studies. We are grateful to Dr otte Anderson for the results with earlier cases, to Dr R ky for the radiographic assessments and to Dr J A H. terhouse for the statistical analyses. We are indebted to J Kemp and Miss M Cutler for technical assistance ally we gratefully acknowledge financial assistance from United Birmingham Hospitals Research Fund and the ical Research Council.

ST THOMAS'S HOSPITAL, LONDON

A PRELIMINARY investigation has been made into the effects of irradiating carcinomata in patients breathing oxygen at a pressure of three atmospheres absolute (30 lb per square inch gauge pressure) This was suggested by the findings of Gray et al (1953) who showed that the sensitivity of tumour cells to irradiation was increased in mice breathing oxygen

It appears to be a general principle that the sensitivity of all cells to irradiation is related to the oxygen concentration in their environment This sensitivity increases rapidly as the oxygen concentration increases to a critical level above which there is little further change

Evidence has been obtained from the structure of neoplasms that they contain cells which in relation to those of normal tissues are in a poor state of oxygenation (Thomlinson and Gray 1954, 1955) An increase in the concentration of oxygen around these cells would therefore cause a relatively greater increase in their sensitivity to irradiation

This encouraged us to investigate the possibility of improving the treatment of patients Firstly we considered the physiological and technical problems involved To reach a pressure of three atmospheres a pressure chamber is required Exposure to oxygen at high pressure for more than short periods is liable to cause convulsions (Bert 1878 Thomson 1935 Donald 1947 Lambertsen et al 1953) In animals, however the onset of convulsions can be retarded by barbiturate anæsthesia (Marks 1944 Taylor 1954 Churchill Davidson 1954) We have therefore anæsthetised our patients before the administration of oxygen They were thus not susceptible to alarm at being enclosed in the chamber or to the severe pain which is sometimes felt in the paranasal sinuses in atmospheres of high pressure

Because of the possibility of extensive rupture of the tympanic membrane or hæmorrhage in the middle ear bilateral myringotomy was done Small polyethylene tubes such as have been used in the treatment of chronic secretory otitis media (Armstrong 1954) kept the perforations patent during treatment

It is impossible to remain in the same room as the pressure chamber during irradiation but contact with the patient can be maintained electrically We have used an electrocardiograph an electromyograph from the upper lip to detect the possible onset of convulsions and a thermistor mounted on the outlet of a carbon dioxide absorbing canister to obtain a tracing of the respiratory rate Special precautions were necessary to avoid static or other sparking because of the risk of fire or explosion

We used a modified naval diving recompression chamber (fig 1) This consists of a steel cylinder measuring internally 7 ft 6 in × 2 ft 6 in with a door at the head and secured by swing bolts It is mounted on four swivel wheels and can be moved by two people although it weighs two tons There are two observation ports in the door and on top of the chamber is a recessed window 25 cm sq of 1 in Perspex through which the patient is irradiated At the foot end of the chamber is an inlet manifold connected directly to four 120 cu ft oxygen

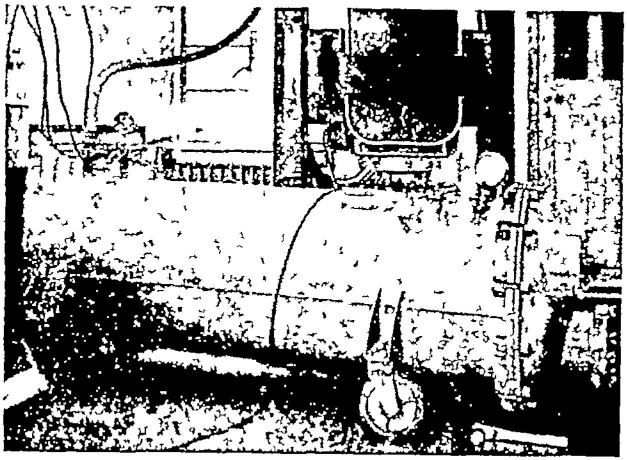

Fig 1—Pressure chamber in position under X-ray unit

cylinders without reducing valves A pressure gauge is attached to the manifold There are also a safety valve and a $1^1/_2$ in exhaust valve from which the oxygen is discharged from the building through a hose pipe At the head end of the chamber are a gauge measuring the pressure within the chamber, a fine needle exhaust valve, and a second safety valve Inside the chamber is staging on to which slides a metal trolley carrying the patient To get this easily in and out of the chamber a second trolley has been made on to which the first slides (fig 2) The electrical leads pass out of the chamber through a pressure gland and are connected via twin amplifiers to a double-beam cathode ray tube One beam is used to make the tracing from the thermistor and the other to make a combined tracing from the electrocardiograph and electromyograph A second cathode ray tube and camera enable these tracings to be photographed (fig 3)

The radiotherapy apparatus is a standard 250 kV unit filtered to give a half-value layer of 1 70 mm of copper (in treating one of the breast tumours—case 6—this was reduced to 1 15 mm to get a higher dosage rate)

To obtain results quickly we tried to determine whether the expected increase in radiosensitivity was demonstrable histologically To do this we treated patients with carcinomas large enough to be divided into two fields for irradiation One field was irradiated with the patient breathing air at atmospheric pressure, and the other with the patient breathing oxygen at three atmospheres in the pressure chamber Each field was irradiated once only with the same dose of X rays To compare the effect on

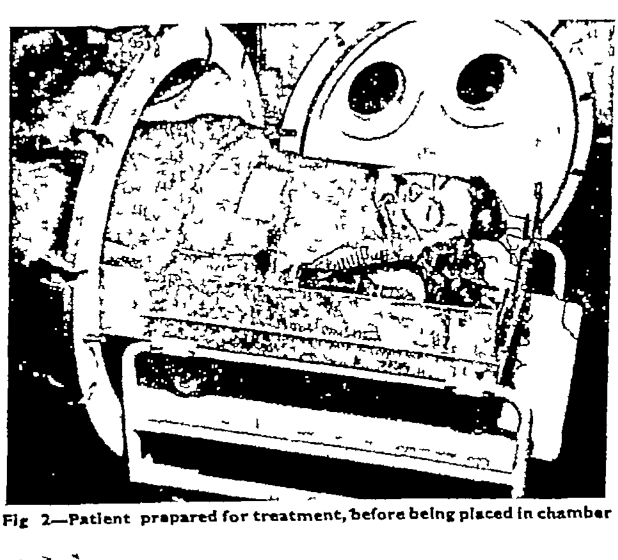

Fig 2—Patient prepared for treatment, before being placed in chamber

the two fields a dose was given (1000–1500r at the which was insufficient to kill all the cells After an a biopsy specimen was taken from each field, or growth was excised, and the pathologist was told the dividing line between the fields lay but not field had been irradiated in oxygen

Eight patients were treated four had carcino the lung, and four carcinomas of the breast (two local recurrences after mastectomy) The breast were treated in two anterior fields and were divid covering one half with lead sheets

The lung tumours were treated in directly op anterior and posterior fields To obtain an ac line of division the patients were screened in the positions in which they were to be treated With patient supine a wire mesh grid was placed on the an chest wall and adjusted so that the central wire directly over the proposed line of division The grid then outlined on the skin surface with a dye so th could be replaced in the same position With the tube centred over it an anteroposterior picture was (fig 4) The whole procedure was then repeated with patient prone and the grid on the posterior chest wall, a postero anterior film was taken When the films been developed, the grids were replaced and the marked with any small adjustments necessary

Procedure

Premedication —Phenobarbitone gr 1 was given hours before treatment, and atropine gr $^1/_{\rm 0}$ 'Omnopon' gr $^1/_6$ one hour before treatment In 7 and 8 chlorpromazine 50 mg and pethidine 100 were given intramuscularly instead of omnopon

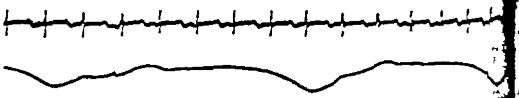

Fig 3—Electrocardiograph and breathing traces Any mov the patient s upper lip will cause an electromyograph tra superimposed on the electrocardiogram The notches in the ing trace are caused by closure of the valves

Anæsthesia and Myringotomy —Pentobarbitone in 5% solution was injected intravenously thro Gordh needle at the rate of 1 ml a minute until cons ness was lost, 0 25 g usually sufficed, but in one 0 75 g was needed Pethidine 100 mg was then slowly through the same needle, followed by choline 50 mg In cases 7 and 8 only chlorpr 50 mg was given with the pethidine The patient's were next inflated with oxygen and, after the trach vocal cords had been sprayed with 4% lignocaine, largest convenient endotracheal tube was passed direct vision The tube was secured, and a metal of sufficient size to prevent biting of the tube was Controlled respiration was applied until sp breathing returned, this was done with 75% oxide and 25% oxygen while the myringotomies performed The anæsthetic machine was then nected and the patient allowed to breathe air

Preparation for Treatment —At this stage the was transferred to the pressure-chamber trolley, carbon-dioxide absorber was connected, and the trodes were applied to the left leg, upper lip, and arm To confine the irradiation to one of the fields time the other field and the surrounding skin covered with lead sheets 2 mm thick (or thickness of lead rubber), and the tube was placed its central ray passed through the middle of the di line When the patient had been correctly placed chamber, the height of the X ray tube was adju that the anode skin distance was 60 cm, and the ele connections were completed

Compression —Before the door was closed the ch was flushed with oxygen to wash out the air The es were closed oxygen allowed ow into hamber ll the uired ure was ched pression carried fairly wly to nimise bon di le reten n (Bean 5) and perature anges bout 10 nutes ally be allowed Treatment l Decom- ssion — eatment bk on average 40 minutes for each field After this the ent was slowly decompressed In the patients with ast tumours this took about 7 minutes. It could bably be done in less time because bends' (caisson ase) rarely occur with oxygen, but excessive cooling the patient might occur Decompression of patients h lung tumours was done more slowly taking about minutes This was because of the risk of damage to lung beyond a partially blocked bronchus by oxygen aining at a higher pressure

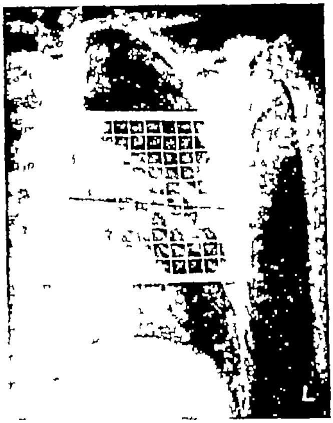

Fig 4—Anteroposterior radiograph showing wire-mesh localising grid in position. The dark line across the grid is that about which the tumour was divided into two irradiation fields.

Case reports

ase 1 —A woman aged 40 had an extensive carcinoma he left breast, which was swollen hard and fixed There e multiple nodules in the overlying skin and erysipeloid ltration extending wide of the breast in all directions. arged fixed glands were present in the left axilla and supra vicular region. The left arm was dusky and swollen and re were engorged veins around the shoulder

reatment —The breast region was divided transversely t above the nipple into two irradiation fields. The upper d was the larger having an area of 330 sq cm. and included cervico-axillary lymph chain The lower field was 120 sq A single dose of 1000r was given to each area, the upper d being irradiated with the patient breathing oxygen at e atmospheres and the lower field four days later with patient breathing air at atmospheric pressure

esult —The skin reaction in the field irradiated during the alation of oxygen was slightly more than that in the field diated in air There was dramatic regression of the tumour both fields but clinically there was little difference between m. As swelling diminished the primary tumour was nd to be in the upper and outer quadrant of the breast— wholly in the field irradiated in oxygen.

iopsy of each field 14 days after treatment showed skin a little subcutaneous tissue There was lymphatic ation of the dermis but few tumour cells were present in er specimen In the tissue irradiated in air there were e undamaged tumour cells than in the tissue irradiated oxygen, in which there was also more inflammatory ponse

ase 2 —A man, aged 61 developed a recurrence of carcin a of the left breast beside the scar of a radical mastectomy e two years previously It measured 73 × 67 mm was d to the chest wall and was fungating through the n. Lying lateral to it separated by about 20 mm of appar ly healthy skin was a nodular skin recurrence 10 mm. diameter In addition there were another skin nodule 7 5 mm in diameter in the medial infraclavicular region and small fixed glands in the left axilla and supraclavicular region

Treatment —The main mass was divided diagonally into two irradiation fields, and each was given a single dose of 1000r One was irradiated with the patient breathing oxygen at three atmospheres, and the other two days later, with the patient breathing air at atmospheric pressure The skin nodule lateral to the main mass was treated in oxygen simultaneously with the first field.

Result —Striking regression of the main mass resulted but there was little difference in the flattening of the two halves or in the skin reactions

Biopsy specimens were taken from apparently comparable areas of each field 16 days after treatment These consisted of skin and subcutaneous tissue with large numbers of tumour cells in the dermis. In the tissue treated in oxygen a higher percentage of tumour cells had been damaged and there was a greater inflammatory response In the tissue treated in air there were undamaged cells and a few in mitosis.

Skin Nodules —The skin nodule treated in oxygen had completely disappeared 14 days later For comparison the nodule in the infraclavicular region which had not been treated was allowed to reach a diameter of 10 mm and then given a single dose of 1000r in air Three weeks later it had shown only slight regression, then being 8 mm in diameter

Case 3 —A man aged 48 had a large mass in the hilar region of the left lung The left upper lobe bronchus on tomography appeared to be completely blocked and the lower lobe bronchus narrowed This was confirmed by bronchoscopy

Treatment —The growth was treated in one session each half receiving a minimal tumour dose of 1000r from opposing 8 × 15 cm. fields. The lower half was treated with the patient breathing air and one hour later the upper half with the patient breathing oxygen at three atmospheres.

Result —On radiography one and two weeks after treatment there appeared to be a dramatic regression of the tumour. The skin reaction was more marked in the field treated in oxygen but the difference was not great Three weeks after irradiation a left pneumonectomy was done No difficulty which might be considered due to irradiation was experienced.

Operation Specimen —The tumour was an oat-cell carcinoma arising in the upper lobe bronchus With the exception of a few tumour cells in a lymph node in the hilum all the cells in both fields appeared to be necrotic

Case 4 —A woman aged 53 had had a radical mastectomy for carcinoma of the right breast No postoperative irradiation was given. For nine years she remained clinically free from recurrence but then began to develop multiple local skin nodules and later glandular metastases These were treated as they arose some surgically and others by irradiation Thirteen years after the mastectomy she developed two skin nodules, each 7 mm in diameter 20 mm. apart in previously unirradiated skin

Treatment —A single dose of 1500r was given to each nodule one with the patient breathing air and the other about half an hour later with the patient breathing oxygen at three atmospheres.

Result.—Three weeks later there appeared to be slightly more regression of the nodule treated in oxygen, but the difference was not sufficient to be conclusive There was no difference in the skin reaction in the two areas. The nodules were then excised

Histology —In each nodule there were areas of tubular cuboidal and columnar cell carcinoma and no damaged tumour tissue was present It appeared from serial sections that active growth was taking place in each nodule but to a lesser extent in the one treated in oxygen in which there were also more chronic inflammation and fibrosis

Case 5 —A man aged 59 had a large mass in the lower lobe of his right lung It was found on bronchoscopy that the basal branches of the lower lobe bronchus were completely obstructed by a tumour This was a poorly differentiated squamous carcinoma.

Treatment —The growth was divided diagonally into two irradiation fields of equal size The lower and inner area was treated with the patient breathing air about an hour later the upper and outer area was treated with the patient breathing oxygen at three atmospheres Each area received a minimal tumour dose of 1000r from opposing triangular fields 15 × 15 × 21 cm

Result —Radiography 12 days after treatment showed no regression Sixteen days after treatment a right pneumonectomy was done

Histology —The tumour was approximately spherical and 8 cm in diameter It occupied most of the lower lobe of the lung and infiltrated the diaphragm and pericardium But for an incomplete rim of carcinoma 1–3 mm wide the whole mass was necrotic In this rim there appeared to be more irradiation damage in the upper and outer area

Case 6 —A woman, aged 57, had a firm tumour measuring 7 5 × 6 cm in the lower outer quadrant of the right breast This was fixed to the overlying skin, in which there was a small ulcerated area, and to the underlying muscle There was also extensive infiltration of the surrounding skin

Treatment —The tumour was divided into two fields for irradiation in a sagittal plane The lateral field, which measured 10 × 15 cm , was irradiated with the patient breathing air About an hour later the medial field, which measured 12 5 × 15 cm , was treated with the patient breathing oxygen at three atmospheres A single dose of 1500r was given to each area Owing to the rounded contour it was impossible to avoid a small area in the centre of the main mass receiving irradiation from both fields, but this was minimised by leaving a gap of 1 cm between the adjacent edges of the two fields

Result —A local mastectomy was done 10 days after irradiation At this time there was no obvious regression in either half of the tumour, and the skin reaction, a mild erythema, was similar in each irradiation field

Histology —The main tumour mass measured about 3 × 3 cm , and 1 5 cm between the retracted skin and muscle It was an acinar polygonal cell carcinoma in which a few tubules lined by columnar cells had been formed There was extensive infiltration of the dermis beyond the main mass The most severe damage caused by irradiation had occurred in the primary tumour close to the dividing line between the irradiation fields Tumour cells in the dermis in the field treated in oxygen had been damaged by irradiation There was some damage, probably less, to tumour in the region thought to have been treated in air only, but this was too near the line of division for us to be sure that it was not affected by the overlapping of the fields

Case 7 —A man, aged 48, had in the hilar region of his left lung a large mass which had obstructed the origin of the upper lobe bronchus

Treatment —The tumour was divided transversely for irradiation, each half receiving a minimal tumour dose of 1000r from opposing fields measuring 7 5 × 15 cm. The lower half was treated with the patient breathing air, and then about an hour later the upper half with the patient breathing oxygen at three atmospheres

Result —Radiographs, including tomograms, taken 11 days after treatment showed much regression of the growth but no demonstrable difference between the amounts in the two areas Thirteen days after irradiation a left pneumonectomy was done

Histology —The tumour arose in the lingular branch of the upper-lobe bronchus and measured about 25 × 15 × 15 mm There was extensive infiltration of the hilar lymph nodes, the walls of the upper lobe and lower lobe bronchi, and the adjacent lung tissue The tumour was a poorly differentiated round cell and polygonal cell carcinoma In the central portion, about the dividing line, was much necrosis In comparable fields near the upper and lower limits of irradiation was much more damage to the tumour cells in the upper part, which was irradiated in oxygen

Case 8 —A man, aged 62, had a mass in the hilum of his left lung with consolidation of much of the lung distal to it The mass was found to be a poorly differentiated squamous carcinoma

Treatment —The tumour was divided transversely for irradiation, each half receiving a minimal tumour dose of 1000r from opposing fields measuring 10 × 12 cm The lower half was treated with the patient breathing air, and the upper half about an hour later with the patient breathing oxygen at three atmospheres

Result —Radiography a week after treatment showed no mat [illegible] Ten days after treatment thoracotomy was done A large growth at the hilum was found to be ir because of extensive involvement of the aorta

Biopsy specimens were taken from the upper and halves of the growth These contained small amounts of and trabecular squamous carcinoma There appeared to more irradiation damage in the specimen from the upper

Results

Satisfactory, though experimental, apparatus and nique have been developed for the irradiation breathing oxygen at high pressures

Eight patients were treated without mishap or com cation attributable to the treatment

The pathologist was not told which part of the had been irradiated in air and which in oxygen cases (1, 2 4, 5, 7, and 8) the tissue which he to be the more damaged was that irradiated in ox This was also probably true of case 6, but the of the experiment were not fulfilled, the pathologist been told, because of some misunderstanding about dividing line, which tissue was which In case 3 distinction was made because none of the tumour either field had survived

Discussion

Empirically oxygen is known to enhance the da caused by irradiation, and, although the mechanism understood, some possibilities have been discussed (G 1953) The relation between the tension of ox dissolved in the environment of the cells and the d of damage which occurs follows a common patt plants and animals, both in vivo and in vitro G this relationship is represented by a curve rising ste from zero and then flattening out suddenly as the s tivity to irradiation almost ceases to be affected by further increase in oxygen tension During the ris sensitivity of the cells is increased by three times T this it would be expected that tissues with poor b supply would be much more affected by irradiation oxygen than would normally oxygenated tissues

Since there are areas in almost every malignant where there is necrosis caused by poor circulation, are likely to be areas of living cells in various deg oxygen deficiency It is postulated that the res of oxygen will increase the sensitivity of these cells irradiation damage and so produce a relative increase the amount of damage to the tumour as a whole compa with normal tissues As a corollary it is also postula that, if poorly oxygenated cells survive the ma doses of X rays tolerable in normal practice, they ma because of the inflammation following death of the be oxygenated tumour cells, receive a blood supply for them to continue to multiply

The work done by Gray et al (1953) on irradi during respiration of high pressure oxygen was con to plants and laboratory animals Their results sufficiently encouraging to warrant an early trial in Many investigations are being conducted with oxyge one atmosphere, and at least one encouraging rep been published (Hultborn and Forssberg 1954) We that information was urgently required about the ef of irradiation in patients breathing oxygen at atmospheres

This pressure has been used experimentally, but t is as yet no definite evidence that it is ideal in particular tumour It seems likely that different p will be required to produce the optimal results in tum with different circulatory conditions

In the treatment of our patients we have assumed Gray that, to be effective, oxygen and irradiation be administered simultaneously We are aware that it been suggested (Gerschman et al 1954) that oxygen po ing and the effects of irradiation have a mechan common, which may be cumulative even if the is breathed within a few hours after irradiation

We have explained as fully as possible the experimental ature of the treatment to each of our patients and have tained from each specific permission to do all that we tended In selecting patients for treatment care was ken to choose only those with advanced disease In es 3 5 6 7 and 8 the surgeon considered the growth be of doubtful operability, and in these the irradiation s given as a preoperative measure In cases 1, 2, and the presence of metastases made palliative irradiation only possible treatment

The apparatus we have used is experimental and has limitations for instance it is only possible to treat mours in the upper half of the body and only one field a time can be treated without decompressing and ving the patient Although the procedure has been e, it has been tedious and time-consuming, taking up six hours for a single patient This however, was tly due to our treating the tumours in two separate rations, and partly to the low output of our X ray it.

As regards anæsthesia, the main problem has been to p the patient safely anæsthetised for a long period ing which he was inaccessible to the administration of ther drugs. Pentobarbitone sodium was suitable for purpose as well as for delaying convulsions, but the essity for using an endotracheal tube to guarantee an way caused difficulty due to coughing This could not overcome by local anæsthetic or cough-depressant gs Therefore in later patients chlorpromazine has n added although it is known that this may alter ulation rates in the tissues this factor however, probably not important Chlorpromazine has the antage of being itself a protection against oxygen vulsions (Paton 1955)

The prevention of carbon dioxide accumulation in the mber is of great importance because the inhalation even small percentages of this gas accelerates the onset oxygen convulsions It is essential that all expirations passed through an absorber To avoid inspiratory istance two one way valves were used which enable patient to breathe in directly from the surrounding osphere and out through the absorber Since the nistor only gives the respiratory rate we hope in ure to get additional information by incorporating a rophone in the endotracheal tube The anæsthetic blems and technique are discussed in detail elsewhere nger et al 1955)

The anæsthetic was completely effective in preventing vulsions and no late complications were experienced patients were warned of possible slight temporary s of hearing after treatment In practice this was nimal and did not usually last more than twenty four rs. Since each patient was only treated in the pressure mber once the polythene tubes used to keep the ringotomy perforations patent were removed imme- tely afterwards If it were intended to give serial atments they could, however be left in situ for several eks without ill effect

Because of the dose given and the area treated radiation kness was anticipated Therefore dimenhydrinate mg and pyridoxine 20 mg were given three times ly for five days, and no radiation sickness developed case 7 to ascertain whether oxygen was protecting inst sickness we omitted these drugs and moderate iation sickness resulted

The difficulty of obtaining a sharp dividing line ween the two irradiation fields in lung tumours has ited us to treating comparatively large growths In te of the precautions taken we have assumed when ing biopsy specimens or examining the whole speci n that there was an area of overlap and confined our ention to areas of the tumour farthest from the ding line The whole object of the histological exam tion was to see if there was a recognisable difference between tumour tissues treated in the two different ways The main difficulty was to ensure that the areas examined were as far as possible comparable In some cases the pathologist selected the tissue irradiated in oxygen from the appearance of the tumour cells alone but in others indirect evidence such as the degree of inflammatory reaction was taken into account Because of this the reasons for the selection in any single case are open to criticism but the total result of the selections sufficiently suggests an increased effect of irradiation in oxygen to warrant a more extensive trial

It will be noted that the interval between treatment and either biopsy or excision of the tumours varied between one and three weeks. We are now of the opinion that when using doses designed to leave some viable cells, the best time to assess the damage is from seven to ten days after treatment Assessment later than this may be more difficult because surviving cells will have had time to produce fresh islets of growth—e g , case 4

We do not think that more conclusive evidence can be obtained from proceeding along these lines, and therefore we have planned a controlled trial using potentially curative doses to the whole tumour In this we also hope to ascertain the optimal pressure of oxygen though this is likely to vary for different tumours The work of Howard Flanders and Wright (1955) suggests that with irradiation to high dosage the addition of oxygen may bring an increased liability to bone necrosis owing to its normally poor oxygenation This difficulty is likely to be overcome when higher-energy irradiation becomes available because this is less absorbed by bone

Summary

A preliminary investigation was made in which eight patients with carcinomata were given radiotherapy while breathing oxygen at three atmospheres absolute

Satisfactory, though experimental, apparatus and technique are described

The results sufficiently suggest an increase in the radiosensitivity of tumours so treated as to warrant a more extensive trial

We express our gratitude to Sir Robert Davis without whose generosity in providing the pressure chamber this investigation would not have been possible; Dr L. H. Gray Dr O C A Scott Dr J A C Fleming Mr G H Bateman, Dr H J Taylor the surgeons and diving officers of H.M.S. *Vernon* and H M S *Reclaim* Dr A Glucksmann Dr F G Spear Dr P Bauwens, Dr G L Gryspeerdt Dr A. THE pH AND BUFFERING POWER OF HUMAN BILE

UNIVERSITY OF BIRMINGHAM

Much time has been spent in investigating the relation of acid secreted in the stomach to ulceration in the duodenum, but little on determining the factors that may neutralise the acid The pH and buffering power of bile have been thoroughly investigated in animals, but scarcely at all in man and we describe here the results of such an investigation

Bile is commonly regarded as alkaline in reaction Okada (1916) stated that the pH varied between 7 7 and 8 6, but the specimens which he examined were pathological Most workers have obtained their material from biliary fistulæ, and loss of carbon dioxide may have affected their results The investigations of Barry and Levine (1924), Carnot and Gruzewska (1925), Stern (1926, 1928), and Reinhold and Ferguson (1929) reveal a pH range of 5 4 to 7 8 As regards buffering power, Jones (1930) found in dogs that hepatic bile was not as effective as pancreatic juice , Schultz Brauns (1927, 1929) showed, also in animals, that bile was weakly buffered when its acid content was low Neubauer (1923) investigated the buffering power of human bile , but since the indicators he used were phenol phthalein and methyl-red, the range investigated was pH 9 1 to 5 2—which is far removed from the pH of chyme as it enters the duodenum

Nature of Specimens

Bile was obtained from the gall-bladder at laparotomy 20 samples (classified as "normal") were taken from patients with no disease of the liver or biliary apparatus (laparotomy was done in 10 for duodenal ulcer, in 4 for gastric ulcer, in 2 for appendicectomy, and in 4 for diagnostic purposes) 10 samples of "abnormal" bile were obtained from patients with disease of the liver or ducts (7 with gall stones, and 3 with malignant dep in the liver)

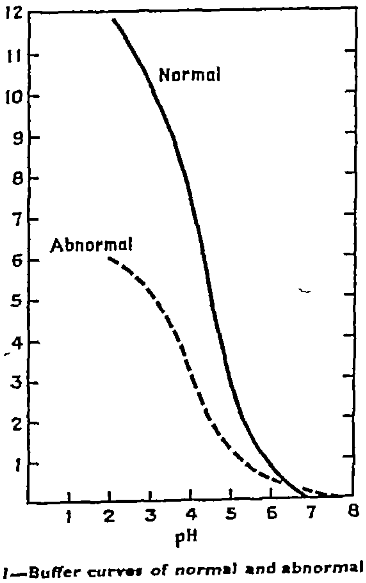

Fig 1—Buffer curves of normal and abnormal bile

7–10 ml of bile was aspirated through an 18-gauge into a sterile syringe lined with neutral paraffin. At first contents were discharged into a test tube under liquid which served as a seal against loss of carbon dioxide, this step was abandoned, and if storage was necessary analysis the bile was sealed in the syringe (a small of mercury being introduced for ease of subsequent and the whole placed in a refrigerator

Methods

The pH of each sample was determined by means direct reading meter, with glass electrode and calomel capable of recording to within 0 05 unit For buffering capacity, *titrations were made on 5 ml.* using 0 1*N* hydrochloric acid, since this reproduces the of gastric juice To determine the buffer value the quantity of acid added should, theoretically, be so as not to disturb the buffer acid/salt ratio , but a *approximation can be made by adding just sufficient to* a measurable change within the limit of accuracy meter For these titrations, therefore, 0 2 ml. of acid *added for each reading , titrations* ceased when the had been brought to pH 2 0 Thorough mixing was *at each addition of acid until a stable reading* was since surface acting agents such as bile salts prevent adjustment of potential Pilot experiments showed that bile suffered no alteration in buffer capacity, though the pH might alter within 0 5 of a unit, on exposure to periods of up *to 4 days Accordingly, no precautions* taken to avoid atmospheric contact during titration total solids in each sample were measured by drying oven at 110°C until a constant weight was reached

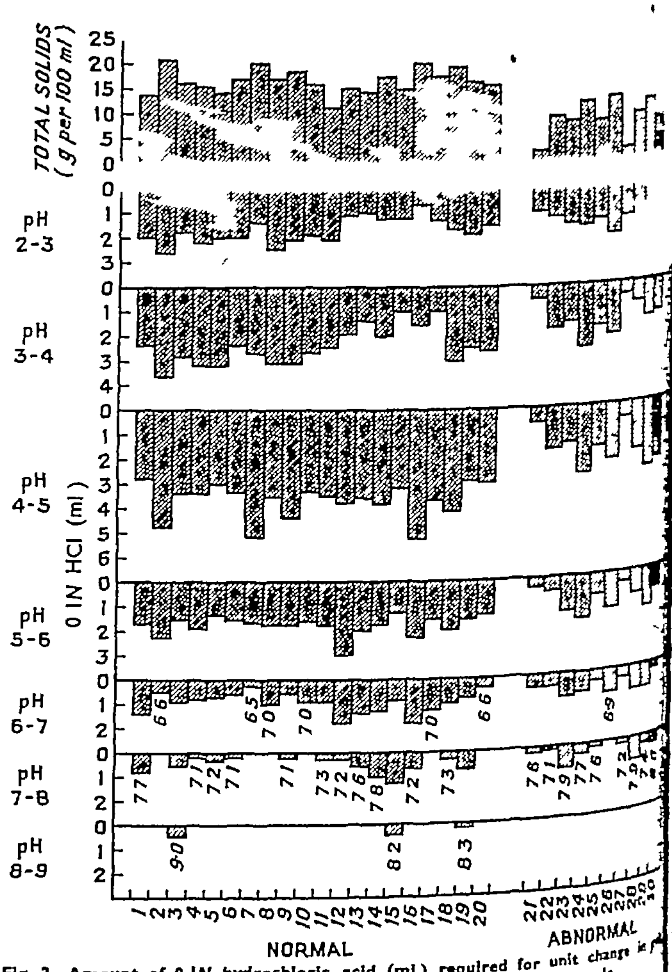

Fig 2—Amount of 0 1N hydrochloric acid (ml) required for unit change in pH of the sample
Figures under each column indicate original pH of the sample

Results

The pH of bile from 3 patients was acid (pH about
) in the 27 others it was either neutral or alkaline
e accompanying table) There was little difference
tween the 20 normal and the 10 abnormal samples
e ranges being 6 5–9·0 (mean 7 3) and 6 9–8 0 (mean 7 6)
pectively There was no apparent relationship between
e pH of each sample and its weight of total solids

Buffer curves were prepared by plotting pH readings
ainst the volumes of 0·1*N* hydrochloric acid added
g 1) For ease of comparison and better understanding
diagram has been constructed showing the amount of
d required for each unit change in pH (fig 2) In 28
mples it was found that the maximum buffering
pacity lay in the range pH 5–4 In no sample of normal
le was less than 2 9 ml 0 1*N* hydrochloric acid required
carry the pH from 5 to 4 (range 2 9–5 3 mean 3 7)
hereas none of the abnormal bile samples required
ore than 2 8 ml (range 0 7–2 8 mean 1 9) The total
lids were found to be related to the buffering capacity
d this was further reflected in the fact that the weight

solids for normal bile samples was 11 0–21 0 g per
0 ml compared with 3 8–12 8 g per 100 ml for
normal bile The initial pH of a sample was no indica
n of the total buffering capacity to pH 2 0 for
ample sample 3 (see accompanying table) was alkaline
pH 9·0 but absorbed no more 0 1*N* hydrochloric
id than did sample 7 which was originally acid at
H 6·5

Summary

The pH of human bile obtained from the gall bladder is
ally neutral or alkaline but may occasionally be acid

The pH range of bile in patients without liver or biliary
ease does not differ from that in patients with such
ease but the buffering capacity is greater

Bile acts best as a buffer between pH 5 and pH 4.

The pH of bile does not vary with the proportion of
tal solids but the buffering capacity is apparently
ectly related to the weight of total solids In disease
the liver or biliary tract the total solids are decreased
d the buffering capacity is correspondingly diminished

By injecting tracer doses of ^{42}K intravenously, we can make manifest the transfer of potassium from the blood stream to the tissues

In any given capillary bed the amount of potassium exchanged will depend on the speed of perfusion, and on the speed of exchange of potassium across the capillary wall At one extreme the circulatory transit time of a potassium ion will be infinitely less than the time of exchange of K ions across the capillary wall which we may call exchange time , at the other extreme the exchange time will be infinitely less than the transit time.

The consequences of these two possibilities are predictable (fig 1) When the transit time is much shorter than the exchange time most of the entering K will leave in the venous blood there having been insufficient time for exchange the plasma ^{42}K level will fall only slowly and the organs will take up ^{42}K in proportion to their exchange rate for K On the other hand when the exchange time is much shorter than the transit time most of the entering K will go into the tissues the plasma ^{42}K level will fall very rapidly indeed and most of the injected ^{42}K will initially be found in those organs which have a high blood flow

This distribution of ^{42}K in proportion to blood flow will of course be transient for the same organs which rapidly take up ^{42}K when the plasma ^{42}K level is high will also discharge it when they are again perfused with K of low specific activity (S A)* and ultimately the various tissues contain ^{42}K in proportion to their content of chemical K

We summarise here the results of experiments which suggest that the initial uptake of ^{42}K by organs is a function of their blood flow rather than of their K content This suggests that for potassium, the rate of exchange in tissues is very high the exchange time being much less even than the short time taken for circulatory transit

Observations

Disappearance from Plasma

After rapid intravenous injection of a tracer dose (50–100 μC) of ^{42}K successive samples of arterial blood show a peak of activity about 50% of the dose per litre

---

* The specific activity is the ratio of radioactive potassium (^{42}K) to total chemical potassium. In this work the amount of ^{42}K is expressed as a percentage of the dose—i e., the amount injected less the amount excreted—and chemical K is expressed as m eq Hence the S A is , dose/m.eq K.

of plasma at 20–30 seconds after the injection Thereafter the injected dose disappears very rapidly from the plasma at 2 minutes 5% of the dose per litre, or less, remains in the plasma, and at 5 minutes less than 1% These results in man are consistent with those obtained by Walker and Wilde (1952) in the rabbit, and by MacIntyre and Leonards (1955) in the dog

Renal Uptake of ^{42}K

The kidneys receive about 20% of the resting cardiac output, but their K content represents only 1–2% of the total body K Experiments on rabbits have shown that 2 minutes after the injection up to 10% of the injected dose can be demonstrated in each kidney (Emery et al 1955) The renal share of injected ^{42}K is clearly much more closely related to blood flow than to K content Kidneys taken out 30 minutes after the injection of ^{42}K contained only 2% of the dose, this disappearance of ^{42}K from the kidneys between 2 and 30 minutes could not be accounted for to any great extent by loss of ^{42}K in the urine, because this was only 1% or less of the injected dose It seemed likely that most of the ^{42}K was returned to the renal venous plasma, but we could not examine this point adequately in rabbits Two experiments in volunteers have shown that during the first half-hour after injection the K of renal venous plasma is of a specific activity higher than that of systemic plasma, and comparable to that of urine—i e, 2–5 times the systemic S A

The unique disproportion between blood-flow and K content in the kidneys makes the dependence of renal ^{42}K uptake on blood flow rather easy to demonstrate, our evidence on other tissues is less conclusive but in no way conflicts with the view that blood-flow is more important than K content in deciding the *early* uptake of ^{42}K

Uptake by Gut and Liver

After oral administration of ^{42}K the S A in the plasma increases slowly, but after 20 minutes it is maintained at a higher level than after intravenous injection (fig 2) Some of this "delay" must be due to the time needed for intestinal absorption, but we believe that the subsequent maintenance of plasma S A is largely due to the discharge of a pool of K of high S A in the gut and liver It is known that 2 minutes after intravenous injection of ^{42}K in the rabbit about 35% of the injected dose can be found in the gut and liver (Walker and Wilde 1952) One minute after intrasplenic injection of small amounts of ^{42}K in the rat more than 50% of the injected dose is commonly found in the liver (G A Lumb, R F Mahler, and S W Stanbury, personal communication), whereas the amount found in the liver after intravenous injection is about 5% (Ginsburg and Wilde 1954) These various observations suggest that gut and liver can take up a high proportion of the K in the blood supplied to them, exchanging cellular K for it

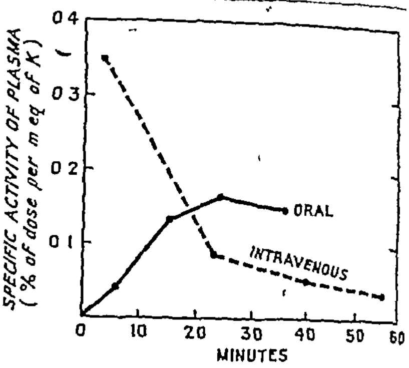

Fig 2—Time-course of specific activity of plasma-K after intravenous and oral administration of ^{42}K.

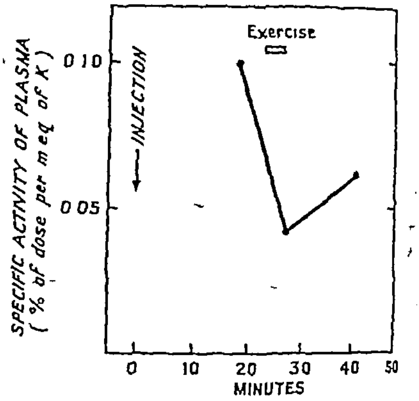

Fig 3—Depression of specific activity of plasma-K by exercise. (Normally, plasma S.A. is steadily falling at this time—cf fig 2.)

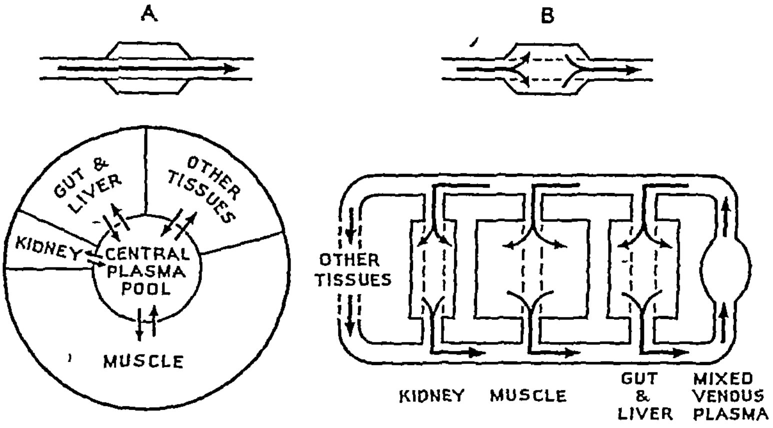

Fig 1—Mechanism of distribution of K among tissues Two limiting cases are shown:

(A) Only a small fraction of plasma K is exchanged during each transit, with the result that the K leaving an organ is essentially that which entered it In these circumstances individual tissues compete for intravenously injected ^{42}K and will take it up in proportion to their exchange rate The activity in the central plasma pool will fall steadily until plasma and tissues are in equilibrium

(B) Almost all the plasma K is exchanged in each transit, with the result that the K leaving the tissue is derived from tissue K rather than from arterial K Intravenously injected ^{42}K will be very quickly cleared from plasma and deposited in the various tissues according to their relative blood flow During subsequent redistribution the specific activity of mixed venous plasma may actually increase, if the circulation is increased through tissues containing K of high specific activity

Uptake by Muscle

Although more than half the body K is in muscle, the blood flow in resting muscle is only about 3 ml per minute per 100 g, in contrast to 270 ml for kidney, and 70 ml for liver (Edholm 1953) In so far as early uptake of ^{42}K is determined by blood flow, muscle will come off very badly relative to its K content, and the K in muscle soon after intravenous injection will be of low S A If blood flow through muscle is then increased by exercise, and if venous effluent from a tissue is mainly derived from tissue K, generalised exercise should produce a "dip" in the curve of plasma S A Such a "dip," induced by weight lifting, is shown in fig 3

It is impossible in man to determine the S A of K in various tissues at intervals after injection of ^{42}K Our own data on rabbits are very limited but Ginsburg and Wilde (1954) have published extensive observations of this type on rats Fig 4 is constructed from their results and shows rather clearly how the initial distribution of ^{42}K depends very largely on blood flow, whereas subsequently redistribution occurs, with an approach to the uniform distribution of ^{42}K which permits the measurement of exchangeable potassium

Conclusions

These findings strongly suggest that the exchange of K between plasma and tissues takes place so rapidly that the K of arterial plasma is largely, if not wholly superseded in venous plasma by K derived from the tissue during transit If this is correct certain consequences follow A tracer dose of ^{42}K given intravenously is almost at once distributed among the organs of the body in proportion to their relative blood supply This initial disposal of injected ^{42}K is followed without pause by a redistribution of ^{42}K whose end result is that the various organs contain ^{42}K in proportion to their potassium content The speed with which the S.A in each organ approaches the final equilibrium value (or more strictly, the S.A in current arterial plasma) will be directly proportional to the blood flow through it and inversely proportional to its K content Since the K in the venous drainage from a tissue is derived from the K content of the tissue the S.A of the mixed venous blood can be raised (or lowered) by altering the circulation so that organs which at the time contain K of high (or low) S.A make a greater contribution to the total venous flow

Even if this theoretically derived pattern of K distribution is only partially correct (and some organs, such as brain are exceptional in their behaviour) our actual results show that tissue and plasma S.A can be greatly influenced by blood flow This makes it unlikely that observations on the amount of ^{42}K in plasma or in individual organs can give any definite information on alterations in the rate of exchange of K across the cell membrane during the phase of initial disposal and subsequent redistribution This type of approach is therefore unlikely to yield useful conclusions on the state of the potassium household

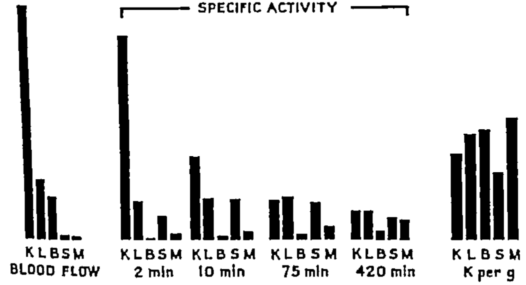

Fig 4—Comparison of time-course of intravenously injected ^{42}K with relative blood flow and relative tissue-K content in kidney (K) liver+gut (L) brain (B) skin (S) and muscle (M) The early distribution of ^{42}K resembles relative blood-flow the later distribution tends towards relative K content; brain tissue is anomalous in its slow rate of uptake of ^{42}K relative to its blood-flow Constructed from results of Ginsburg and Wilde (1954) with the estimates of Edholm (1953) of relative blood-flow

It seems likely that this pattern of distribution is characteristic not of potassium as such but of any substance which leaves the blood stream rapidly in relation to circulatory transit time. In hind limb perfusion experiments Pappenheimer et al (1951) demonstrated a disappearance rate from plasma of this order of rapidity for substances as diverse as chloride deuterium oxide inulin and glucose There are of course substances such as plasma albumin which leave the circulation only slowly and Elgee et al (1954) have shown that the early uptake of ^{131}I tagged albumin is very much less in both liver and kidney than we have described for ^{42}K These two types of behaviour may correspond in a general way to cases A and B in fig 1 A high immediate uptake of a tracer tagged substance by organs with a high blood flow—e g liver and kidney—may be taken as presumptive evidence of rapid transcapillary exchange of that substance

PRESSURE AND DURATION OF INSPIRATION DURING ARTIFICIAL RESPIRATION BY INTERMITTENT POSITIVE PRESSURE

J M K. SPALDING
M.A D M Oxfd M R C P
ASSISTANT DEPARTMENT OF NEUROLOGY RADCLIFFE INFIRMARY OXFORD

ARTIFICIAL respiration by intermittent positive pressure through a tracheostome was introduced in Denmark for the treatment of poliomyelitis (Lassen 1953) and has since been used for that disease for polyneuritis (Crampton Smith et al 1954 Macrae et al 1954 Harries and Lawes 1955), and for severe tetanus treated with relaxants (Bjorneboe et al 1953 Shackleton 1954 Honey et al 1954 Lassen et al 1954)

There is plenty of evidence to indicate that such patients can be kept in reasonably good condition by intermittent positive pressure respiration for many months An acute respiration unit however has to deal with patients in a critical state either from pulmonary complications or from circulatory failure and if such patients are to be saved the factors affecting ventilation provided by intermittent positive pressure must be investigated and considered in connection with the effect of such pressure on the circulation To ascertain the factors at work it is necessary to analyse the effects of changes of inspiratory pressure duration of inspiration and respiratory rate

Method

Measurements have been taken on adults with severe respiratory paralysis who were receiving artificial respiration by intermittent positive pressure through a tracheostome Patients who are not paralysed are not suitable for this type of investigation because muscle tone varies and tends to keep the respiratory minute volume constant (Yandell Henderson 1938) A Stott expiratory valve (Crampton Smith et al 1954) was used and tidal air was measured either by collecting expired air in a spirometer or by passing it through a dry gasmeter * The tidal air recorded is the mean of ten or more respirations Pressure was recorded close to the external end of the tracheal tube and the duration of inspiration was determined by measurement from the pressure records examples of which are shown in fig 5

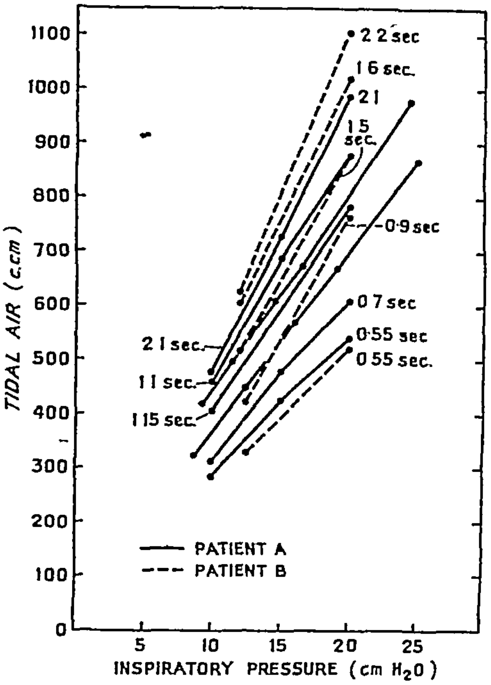

Fig 1—Relationship of tidal air to inspiratory pressure in patients with healthy lungs Duration of inspiration is given in seconds. The pressure record obtained was similar to curves a and b in fig 5

Influence of Inspiratory Pressure on Tidal Air

Fig 1 indicates the changes in tidal-air that result from alterations in the inspiratory pressure The measurements were taken from two patients Patient A had a vital capacity of only 400 c cm, and patient B had complete paralysis of primary and secondary respiratory muscles The lungs of both were healthy Pressures from 9 to 25 cm water, and tidal air from 275 to 1100 c cm, were investigated Fig 1 shows that the tidal air increased in almost direct proportion to inspiratory pressure Fig 2 shows curves taken from patient C, whose bronchial tree contained much secretion When curve *a* was obtained, air entry was generally poor, especially on the left side, and altogether absent over the left lower lobe The curve *c* shows that an increase of pressure of 5 cm water increased the tidal air by only 15 c cm instead of the 100 c cm that would be expected from fig 1 After vibration and percussion of the chest, a gobbet of secretion was aspirated, and air entry on the left side of the chest was considerably improved, though not normal Curve *b* was then obtained about 30 minutes after curve *a*. The situation was improved in that at an inspiratory pressure of 17 5 cm water 120 c cm was added to the tidal air, and at lower pressures the direct relationship between pressure and tidal air was re established At higher pressure, however, the well marked flattening of the curve returned Curve *c* taken a few weeks later, when the chest was clinically and radiologically normal, shows that the pressure/tidal-air relationship was practically normal

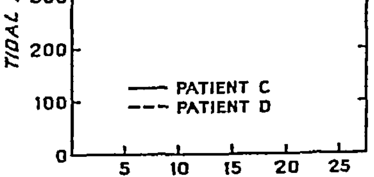

Fig 2—Relationship of tidal air to inspiratory pressure in two patients with abnormal lungs *a*, from patient C with major bronchial obstruction, *b*, after partial clearance *c*, after complete clearance of obstruction *d* from patient D with tetanus when partially curarised, *e*, when fully curarised Gravity operated pump, giving pressure records of type fig 5c was used in plotting curves

Curves *d* and *e* were taken from a patient with severe tetanus treated with paralysing doses of curare (Honey et al 1954) When curve *d* was obtained, the patient was minimally curarised, and owing to muscular rigidity the tidal air was small and was not increased by a rise in pressure Tubocurarine 15 mg was given intravenously, and curve *e* was obtained shortly after The normal relationship of pressure to tidal air was re-established by relaxing the muscles

Conclusion — In the paralysed patient with healthy lungs the tidal air is proportional to the inspiratory pressure within the limits of 275–1100 c cm of tidal air and a peak pressure of 9–25 cm water If, however, there is major bronchial obstruction or much muscular rigidity, as in tetanus, an increase in pressure may produce virtually no increase in tidal air

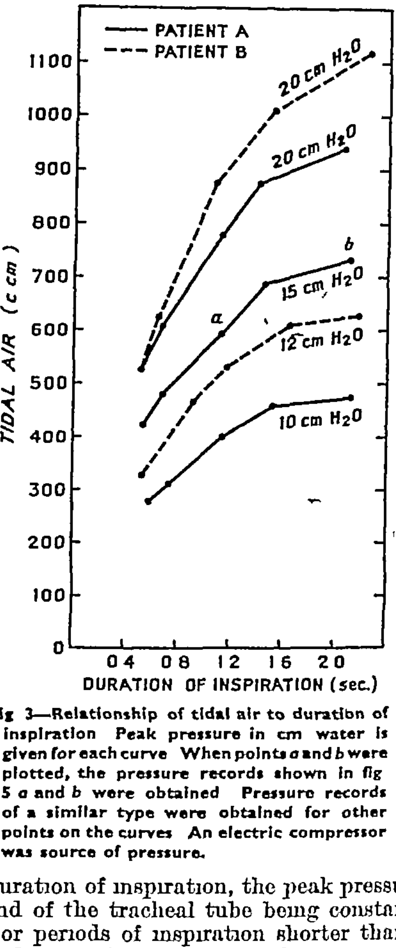

Fig 3—Relationship of tidal air to duration of inspiration Peak pressure in cm water is given for each curve When points *a* and *b* were plotted, the pressure records shown in fig 5 *a* and *b* were obtained Pressure records of a similar type were obtained for other points on the curves An electric compressor was source of pressure.

Influence of Duration of Inspiration on Tidal Air

Fig 3 shows the effect on tidal air of varying the duration of inspiration, the peak pressure at the external end of the tracheal tube being constant for each curve For periods of inspiration shorter than 1 5 sec. there is a distinct decrease in tidal air as inspiration becomes shorter, but the reduction in tidal air is by no means directly proportional to the shortening of inspiration When inspiration exceeds 1 5 sec in duration, the increase in tidal air is only slight The flattening of the gradient in the curves in fig 3 when inspiration is prolonged indicates that, though air continues to enter the patient's lungs even after inspiration has continued for 1 5 sec., its rate of flow is much slower at the end than at the beginning For instance, at a peak pressure of 15 cm water, in the first 0 7 sec 480 c cm of air enters the lungs, in the next 0 7 sec only 190 c cm does so, and in a further 0 7 sec only 55 c cm enters

RELATION OF TOTAL TO EFFECTIVE MINUTE VOLUME

Rate per min	Tidal air (c cm)		Minute volume (c cm.)	
	Total	Effective	Total	Effective
15	600	500	9000	7 5
25	400	300	10,000	7 5

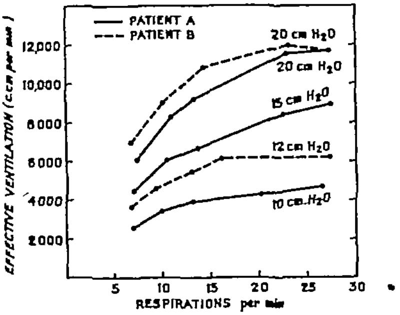

Fig 4—Effective minute volume at different respiratory rates in patients with healthy lungs. Peak inspiratory pressure for each curve is given in cm. of water.

Conclusion.—Within the range of duration of inspiration 0·6–2·2 sec. although the amount of tidal air decreases as inspiration is shortened the relationship is not directly proportional. Inspiration longer than 1·5 sec. provides little useful increase in tidal air.

Influence of Respiratory Rate on Effective Ventilation

Where efficiency of ventilation is concerned it is not total tidal air but effective tidal air (total tidal air minus dead space) that is important. In the presence of a tracheostome the dead space is decreased by by passing the larynx and upper respiratory tract and by introducing a tube into almost the whole length of the trachea. This is partially offset by the volume of the tubing between the patient and the expiratory valve, which is about 15 c cm. For the present purpose the dead space in a patient receiving artificial respiration by intermittent positive pressure is taken to be 100 c.cm. In comparing ventilation at different rates therefore, 100 c.cm. per breath must be deducted from the actual minute volume to give the effective volume. An example is given in the accompanying table which shows that to provide an effective minute volume of 7500 c cm. a total minute volume of 9000 c.cm is required at a rate of 15 respirations per minute and of 10 000 c.cm. at 25 respirations per minute. An extra 1000 c cm. per minute has therefore to be provided at the faster rate to achieve the same ventilation.

There is a further factor to be considered when the respiratory rate is raised—namely that an increase in the respiratory rate reduces the duration of inspiration proportionately. Fig 4 shows the relationship of effective minute volume (i e of actual ventilation) to actual respiratory rate at various pressures making allowance for the shortening of inspiration as the respiratory rate rises. In deriving fig 4 from fig 3 the duration of inspiration has been taken as a quarter of the respiratory cycle. The shape of the curves, however, is not materially altered if another proportion is chosen though they are shifted to the right or the left. At no point does an increase in respiratory rate produce a proportionate increase in ventilation and at rates above 16–20 per minute a considerable rise in rate is necessary to produce an appreciable rise in effective minute volume. Thus by doubling the respiratory rate from 13 to 26 per minute the effective minute volume is increased on the average by little more than 20%.

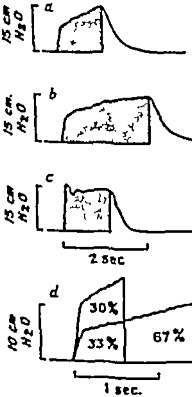

Fig. 5—Pressure at external end of tracheal tube with inspiratory period stippled. Records of type a and b were used in figs. 1, 3 and 4; and of type c in fig 2; d shows two pressure records providing the same amount of tidal air.

Conclusion.—Increase in respiratory rate is a relatively unsatisfactory way of increasing ventilation. Ventilation of the dead space and shortening of the inspiratory period make the increase in actual ventilation slight. This is more particularly the case when the respiratory rate exceeds 16–20 per minute.

Discussion

The observations given above have implications both for the management of patients and for the design of apparatus. They indicate that for the patient without pulmonary complications an increase in ventilation is most readily obtained by increasing the inspiratory pressure. Where complications are present, it may be necessary to increase the respiratory rate, but a considerable increase in rate is required to increase the actual ventilation appreciably. In all cases therefore, it is essential to measure the tidal air directly when the setting of the apparatus is changed and not to rely on deductions from pressure readings. Moreover, in assessing ventilation the effective not the gross minute volume must be considered.

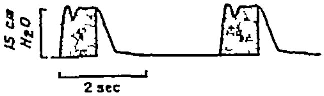

Fig. 6—Pressure record shewing how small the proportion of inspiration can be to the whole respiratory cycle.

One of the dangers of artificial respiration either in a tank respirator or by intermittent positive pressure lies in the strain it places on the circulation by impeding blood flow into the right side of the heart (Werkö 1947, Cournand et al. 1948, Motley et al 1948, Hubay et al 1954). Compensatory mechanisms normally enable a satisfactory cardiac output to be maintained; but if the circulatory mechanisms have been damaged, satisfactory compensation may not be possible. Circulatory mechanisms may be damaged in poliomyelitis by involvement of the circulatory centre and in polyneuritis (Clarke et al 1954). A *similar state of affairs* has been observed in a patient with severe head injury whose respiration had to be maintained by intermittent positive pressure and whose blood pressure became unrecordable during inspiration, recovering to 90/50 mm. Hg during expiration. It is therefore necessary when treating acute cases of any type to allow the circulation every facility for compensation particularly by keeping the inspiratory period as short as possible and so providing the maximum period during which intrathoracic pressure is atmospheric.

Though the *most important factor in* easing the strain on the circulation is probably that inspiration should form a small proportion of the respiratory cycle the circulatory changes have also been correlated with the mean pressure in the face mask or in the type of patient considered here at the external end of the tracheal tube (Werkö 1947, Cournand et al 1948, Motley et al 1948). From fig 3 it can be seen that for example, a tidal air of 400 c cm. could be provided for patient A by an inspiration lasting either 1·5 sec. at a pressure of 10 cm water or 0 64 sec at a pressure of 15 cm water The mean pressure with the shorter inspiration is 30% less than with the longer (fig 5) though the amount of tidal air is the same It is therefore evident that, for a severely ill patient, a short period of inspiration can be used with benefit to the circulation without imperilling the ventilation If inspiration occupies a quarter of the respiratory cycle, there is an inspiratory period of 1 25 sec at 12 respirations per minute, and 1 0 sec at 15 respirations per minute A pressure curve of this type (fig 6) is also suitable for long term treatment and has been used routinely on patient A for ten weeks

Summary

Factors have been investigated which influence the artificial ventilation of paralysed patients by intermittent positive pressure

When the patient's lungs are healthy, the amount of tidal air is almost directly proportional to the inspiratory pressure When, however, there is major bronchial obstruction or (as in tetanus) rigidity of the respiratory muscles, an increase in pressure may produce little or no increase in tidal air

A large proportion of tidal air enters during the early part of inspiration, with the result that adequate tidal air may be obtainable by an inspiratory phase lasting only 0 6 sec Little is gained by prolonging it beyond 1 5 sec, and to do so embarrasses the circulation without providing any compensatory advantage. For the benefit of the circulation in acutely ill patients, inspiration may be reduced to a quarter of the respiratory cycle without prejudice to ventilation

This work has been done in the respiration unit at the Radcliffe Infirmary directed by Dr W Ritchie Russell I wish to thank him and Dr Crampton Smith for much assistance and advice

REGISTRAR IN CLINICAL PATHOLOGY

J A Weaver
M D Belf, M R C P
REGISTRAR IN MEDICINE

From the Royal Victoria Hospital, Belfast, and the Department of Medicine, Queen's University of Belfast

Tetracycline ('Achromycin') is a recently developed antibiotic whose structure and antimicrobial spectrum are very similar to those of chlortetracycline ('Aureomycin') and oxytetracycline ('Terramycin') All three substances have the same chemical nucleus, chlortetracycline differs from tetracycline by the addition of a chlorine atom, and oxytetracycline by the addition of a hydroxyl group, thus tetracycline is the basic structure of the series

Clinical reports by Finland et al (1954) and Wood et al (1954) suggest that tetracycline is as effective therapeutically as the other two antibiotics and in fact may possess certain advantages These include a lower incidence of toxic side effects, and rapid achievement and maintenance of therapeutically effective levels in the serum

To assess its clinical usefulness we have studied the effects of oral administration on 87 patients admitted to the wards of the Royal Victoria Hospital, Belfast Particular attention was paid to the incidence of side effects and to the serum levels achieved by various oral doses The sensitivity of pathogenic organisms, isolated from patients in the hospital, to tetracycline was also studied

Antibacterial Activity

Methods and Materials

Single colonies of the strains required were picked off the routine plates, grown in nutrient broth, and stored until it was convenient to test them The minimal inhibitory concentration for each strain was estimated in the following manner

Tetracycline was incorporated in nutrient agar plates in concentrations ranging from 0 125 µg per ml to 10 µg per ml. The strains to be tested were transferred from 18 hour broth cultures to the plates In each series a plate which contained no tetracycline was included, and on each plate three strains of known sensitivity were streaked *Bacillus cereus* NCTC 8035 sensitive to less than 0 125 µg per ml of tetracycline, *B cereus* NCTC 7464 resistant to more than 2 5 µg per ml. but sensitive to less than 5 0 µg per ml, and a strain of *Pseudomonas pyocyanea* resistant to more than 10 µg per ml

TABLE I—MINIMAL INHIBITORY CONCENTRATION OF TETRACYCLINE FOR 71 STRAINS OF COMMON PATHOGENS

Organism	No of strains	Minimal inhibitory concentration (µg per ml)								
		0 125	0 25	0 5	0 75	1 0	1 5	2 5	5 0	Resistant to >10
B cereus 8035	1	1								
B cereus 7464	1								1	
Ps pyocyanea	3									3
Staph aureus	16	12								4
Strep pneumoniæ	2		2							
Strep hæmolyticus	5	1	4							
Strep viridans	11		2	5	2			1	1	
Strep fæcalis	8		3		3					2
Esch coli	19				12	4	1			2
Bact aerogenes	2					2				
Friedländer's bacillus	3				1	2				

Numerals indicate number of strains inhibited by that concentration and not by any lower concentration

No difficulty was experienced in assessing results, organisms either grew or did not grow

Results

It will be seen from table I that tetracycline is effective against both gram-positive and gram-negative organisms. Gram-negative organisms tended to have higher minimal inhibitory concentrations than did gram positive organisms Organisms may be divided into four main groups

(1) *Those inhibited by 0 25 µg per ml or less*—Among these are the sensitive strains of staphylococci, the pneumococci, the β hæmolytic streptococci, some of the α hæmolytic streptococci, and some enterococci All these organisms are gram positive

(2) *Those inhibited by concentrations greater than 0 25 µg but less than 0 75 µg per ml*—In this group are most of the strains of *Escherichia coli*, one strain of Friedländer's bacillus, many of the α hæmolytic streptococci, and some strains of *Streptococcus fæcalis*

(3) *Those inhibited by concentrations between 0 75 µg per ml and 1 5 µg per ml*—In this group are the strains of *Bacterium aerogenes*, two strains of Friedländer's bacillus, and several strains of *Esch coli*

(4) *Those which are resistant to more than 10 µg of tetracycline per ml*—In this group are found all the strains of *Ps pyocyanea* and some strains of *Staphylococcus pyogenes*, *Strep fæcalis*, and

Esch. coli Because the strains were drawn from hospital specimens it is impossible to be certain if these were naturally resistant strains or had acquired resistance The latter is probable in some cases. Several strains fell outside the groups but they were not considered to be important

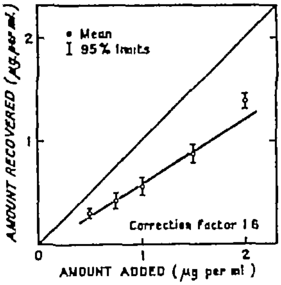

Fig 1—Four-point punch-plate assay of tetracycline: recovery curve Each point is the mean of 10 estimates; 95% confidence limits (2 S.E.M) are marked.

Blood levels

Method

The method was an adaptation of that used by Nelson et al (1954) in the assay of blood penicillin levels The pH of the media was reduced to 6·5 and the indicator organism was *B cereus* (NCTC 8035 Lederle no 5 strain) This method as used in this investigation has certain limitations recovery levels are about 60% between 0·5 µg per ml and 2·0 µg per ml with aqueous standards and accuracy is poor below 0·5 and above 2·0 µg per ml when the standards used are limited to 1·0 and 2·0 µg per ml as in this investigation This method is however simple and *economical of time and material*, and allowed triplicate plates to be used for each estimation Fig 1 shows the graph of recovery levels. Each point represents the mean of ten estimates the 95% confidence limits for each mean are marked

Results

On a dosage of 0·25 g 6 hourly blood tetracycline levels of about 0·75 µg per ml were attained on an average at the end of 16–18 hours Some patients were slow to produce therapeutic blood levels an experience shared by Putnam et al (1953) Because of this and because Transatlantic workers had noted a higher incidence of side-effects with larger doses it was decided to try the effect of a loading dose combined with the 1·0 g daily dosage Accordingly 6 patients were given 1·0 g at the start of treatment and maintained with 0·25 g 6 hourly This mode of treatment produced good blood levels (fig 2) The average level had risen to more than 1·0 µg per ml at the end of 2 hours and at the end of 4 hours the mean blood level was 1·4 µg per ml., with all the levels in the range 0·8–2·2 µg per ml At the end of 24 hours the mean blood level was about 3·0 µg per ml , and no level was below 1·5 µg per ml

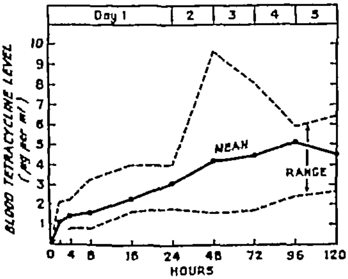

Fig 2—Blood-tetracycline levels obtained in 6 cases with an initial dose of 1 g followed by 0·25 g six-hourly

Clinical Results

Most of the 87 patients in this series were treated for acute infections of the respiratory system The clinical response (table II) was assessed on the duration of pyrexia *subjective improvement, and objective physical and* radiological findings

In *pneumococcal lobar pneumonia* the results obtained were good and in every respect equal to those following the use of chlortetracycline and oxytetracycline

In *acute bronchopneumonia* the results were variable and difficult to assess owing to many other complicating disease processes being present—e g cardiac failure Drug treatment was of necessity started before sputum results were available The organisms isolated from the sputum and considered to be pathogenic were mainly hæmolytic streptococci pneumococci staphylococci, and *Hæmophilus influenzæ* Three patients in this group had on admission been started on penicillin therapy without response and culture of the sputum showed the predominant organism to be Friedländer's bacillus in 2 of these cases and *H influenzæ* in the 3rd When the treatment was later changed to tetracycline in these cases the improvement was dramatic Generally the results in this group were again comparable to those observed with the two analogues

Of the 30 cases of pneumonia of all types it was considered that in 10 cases the response had been less than expected Of these 10 patients 4 had diarrhœa and this side effect exerted an unfavourable influence on the course of the primary illness The remaining 6 patients had other complicating features: 4 had congestive cardiac failure and 2 of these died and 2 had sinusitis.

TABLE II—RESULTS OF TREATMENT IN 87 PATIENTS

Diagnosis	No of cases	Good response	Toxic effect and complication	Poor or no response	Toxic effect and complication
Lobar pneumonia	12	11	0	1	1 diarrhœa
Broncho pneumonia	27	18	0	9	3 diarrhœa 2 sinusitis 4 congestive cardiac failure (2 died)
Chronic bronchitis	17	13	0	4	3 emphysema 1 asthma
Bronchiectasis	8	6	0	2	1 diarrhœa 1 abscess formation
Urinary infection	10	8	1 diarrhœa	2	2 proteus infection
Miscellaneous group	13	11	1 diarrhœa	2	0

Streptococcal pharyngitis (4) carbuncle (3) appendix abscess (2) parotitis (1) epididymitis (1) cholecystitis (1) and glandular fever (1)

Acute exacerbations of chronic bronchopulmonary suppuration formed the next largest group which was composed of chronic bronchitic patients who had developed frankly purulent sputum without pyrexia The *sputum contained mixed cultures of pathogens* mainly similar to those found in the patients with acute bronchopneumonia The results in this group judged by the diminution in amount and purulence of the sputum and by the subjective improvement were surprisingly good and usually better than those following inhalational therapy with either streptomycin or penicillin 4 patients in this series showed no improvement during treatment 1 had recurrent asthmatic attacks and the 3 others had associated advanced emphysematous changes The presence or absence of emphysema and asthma seems to be more important than the nature of the infecting organism in determining the response of a chronic bronchitic to antibiotics Helm et al (1954) also emphasise the importance of deciding whether the asthma is infective or non infective before treating it with antibiotics.

TABLE III—UNTOWARD EFFECTS OF TETRACYCLINE

Daily dose (g)	No of cases	Untoward effects
1	60	5 diarrhœa 12 nausea, 2 skin rash
2	11	2 diarrhœa 1 nausea
Initial loading dose 1, followed by 250 mg 6 hourly	16	1 diarrhœa

Bronchiectasis —There was a temporary improvement with lessening of the amount of sputum in 6 of the 8 patients

Miscellaneous Infections —In this group the number treated was small, but the favourable outcome in the majority of cases compares again with the results obtained with the two analogues In the urinary infections with *Esch coli* the response was particularly good

Side-effects

The side effects so far recorded with the tetracycline group have been mainly gastro-intestinal—e g , flatulence, nausea and vomiting, diarrhœa, and pruritus ani Skin reactions of an allergic type have also been noted (Putnam et al 1953) The pathogenesis of these bowel upsets is not clear , it is generally thought that the upper-intestinal symptoms of nausea and vomiting are related to the chemical structure of tetracycline, and that the diarrhœa is associated with alterations in the intestinal flora secondary to the antimicrobial effect Furthermore, the nausea and vomiting do not necessarily occur in the patients who experience diarrhœa and pruritus ani

Table III shows the incidence of the side-effects in the 87 patients on tetracycline therapy In table IV we have compared the occurrence of the gastro intestinal side-effects in the tetracycline group with comparable groups of patients receiving chlortetracycline and oxytetracycline in equivalent dosage, and in the hospital at the same time The incidence of diarrhœa was roughly similar in all three groups, being highest with oxytetracycline In the 8 cases of diarrhœa in the tetracycline series a careful search was made of the stools for pathogenic organisms Despite the use of selective media, the fæces in all the cases produced a pure growth of *Proteus vulgaris*, but in many other patients who did not experience diarrhœa the predominant organism in the fæces from the fourth day onwards was *P vulgaris*

TABLE IV—COMPARISON OF GASTRO INTESTINAL SIDE EFFECTS OF TETRACYCLINE, CHLORTETRACYCLINE, AND OXYTETRACYCLINE (1 G DAILY)

—	Tetracycline	Chlortetracycline	Oxytetracycline
No of cases	60	60	60
Diarrhœa	5 (8 %)	4 (7 %)	7 (12 %)
Nausea	2 (3 %)	10 (17 %)	7 (12 %)

The incidence of nausea is also shown in tables III and IV , when tetracycline and chlortetracycline were compared in a $2 \times 2\chi^2$ table, it was seen that tetracycline gave rise to significantly less nausea ($0\ 05 > P > 0\ 02$) The numbers were insufficient to carry out this analysis between tetracycline and oxytetracycline, but it will be seen that there is again a lower incidence in the tetracycline group The much greater freedom from gastric upset in the tetracycline group was clearly illustrated in 1 patient who was treated with oxytetracycline, chlortetracycline, and tetracycline successively

A stitcher, aged 20, underwent valvotomy for mitral stenosis in May, 1954 Postoperative pyrexia developed, and blood cultures showed a *Salmonella london* bacteræmia Treatment was begun with oxytetracycline 500 mg 6 hourly After each dose of the tablets nausea and vomiting came on A change to chlortetracycline did not relieve the gastro-intestinal symptoms , but, when tetracycline was substituted, the nausea and vomiting ceased, and therapy was continued with tetracycline for a month

One of the controls had a duodenal ulcer On therapy with oxytetracycline 1 g daily he experienced, after each dose, considerable epigastric burning discomfort which he considered to be exactly like his previous symptoms during an exacerbation of his peptic-ulcer state This suggests that the upper intestinal effects are due to direct irritation of the mucosal surfaces

Discussion

Clinical Results

The clinical outcome in the group of infections treated with tetracycline was very similar to that following the use of chlortetracycline and oxytetracycline and confirms the suggested equivalent therapeutic activity within this group The fact that there is less chance of encountering a resistant organism with the tetracyclines than with penicillin has encouraged some workers to recommend the universal use of the tetracyclines in these acute chest conditions This advantage is somewhat offset by the quicker action and lesser side-effects of penicillin in the infections with sensitive organisms, and for that reason we feel that penicillin should still remain the drug of choice in the initial treatment of pneumonia, and that tetracycline should be reserved for cases which do not respond to penicillin, or where the causal agent has been shown to be penicillin-resistant

In short-term treatment of acute exacerbations of chronic bronchitis tetracycline was extremely effective, and with judicious use the incidence of side-effects is not such as to preclude its use in this type of case. What effect the treatment of acute exacerbations will have on the long term outlook in chronic bronchitis is problematical, but such treatment seems worth trying in view of the eventual complications of this disease The only real barrier appears to be the cost of treatment. but this should probably become less with increasing production, as has happened with penicillin

Side effects

There has been considerable variation (3–30%) in the reported incidence of side effects with the tetracycline analogues, and this has rendered the comparison of results very difficult This variation has been as great with any one drug from worker to worker as the variations recorded between the three analogues A cause of this discrepancy in results is possibly due to different definitions of diarrhœa The degree of diarrhœa varies, being in some cases so mild that the patients will not spontaneously use the word "diarrhœa" to describe their symptoms They state that their motions are a little more frequent, usually to the extent of the passage of three or four large soft formed stools in 24 hours "It is not really diarrhœa, it is more like having taken a mild laxative" Putnam et al (1053) on this basis have classified the upset under the two headings of "diarrhœa" and "loose stools", such a distinction is highly desirable We recognised as diarrhœa only those cases in which frequent watery stools were passed accompanied by unpleasant subjective sensations It is important to emphasise that the mere occurrence of diarrhœa has an unfavourable effect on the course of the primary illness (table II), and that it cannot be regarded as an incidental happening even in the absence of pathogenic organisms from the stools

Finland et al (1954) found the incidence of diarrhœa following the administration of these drugs as follows oxytetracycline 19%, chlortetracycline 10%, and tetracycline 4% The incidence of diarrhœa in 108 patients treated with tetracycline by Waddington et al (1954) was 2 cases, and they thought that this was roughly comparable to that previously observed with chlortetra cycline and oxytetracycline Our experience was that the incidence of diarrhœa was roughly comparable in the three analogues, varying between 7% (chlortetracycline) and 12% (oxytetracycline) In the cases treated with tetracycline examination of the fæces in the cases of diarrhœa did not reveal any pathogenic organisms. A similar finding was reported by Reiner et al (1952) in cases of diarrhœa following the administration of chlortetracycline. These workers suggested that a disturbance of the endogenous bacterial flora of the intestine was in itself sufficient to cause diarrhœa possibly by the sheer quantity of metabolites produced by the abundant growth of an otherwise innocent but resistant organism.

Finland et al (1954) observe that the incidence of diarrhœa rises with increasing dosage as in the present series It therefore appeared essential that we should study the serum tetracycline levels achieved with various dosages and the minimum inhibitory concentrations of tetracycline for the commonly encountered organisms

The minimum inhibitory concentrations for the organisms studied were approximately similar to those found by Tunevall and Frisk (1954) but were usually slightly lower than the concentrations found by English et al (1954) From these figures it seems that the aim in treatment should be the achievement of a serum tetracycline level of at least 1·0 µg per ml as soon as possible Our observations on patients on a dosage of 250 mg 6-hourly showed that the serum tetracycline levels rose slowly and illustrated the extreme variability of absorption in different people, as previously shown by Putnam et al (1953) who found that 3 subjects out of 10 had no demonstrable blood tetracycline level up to 6 hours after the administration of a single dose of 250 mg The administration of 250 mg 6 hourly at best produced levels of 0·75–1·00 µg per ml after 10–18 hours

The dosage of 500 mg 6 hourly ensures a more rapid achievement of effective serum tetracycline levels in the first 24 hours but continued administration of this amount leads to an increased incidence of diarrhœa It appears reasonable to use a larger dosage in the first 24 hours and then to continue with the smaller dosage This could be done either as 500 mg 6-hourly for the first 24 hours or as an initial loading dose of 1 g followed by 250 mg 6 hourly the latter method is recommended because of its simplicity and efficiency Using this scheme we achieved a rapid and satisfactory rise of the blood tetracycline levels in the first 24 hours without any increase in the incidence of toxic effects (table III) probably because the increased incidence of toxic effects with the higher doses takes time to develop usually three days The total amount administered in the first 24 hours is 1·75 g., and the serum tetracycline levels at the end of this period agree very closely with those of Tunevall and Frisk (1954) who administered 1·5 g in the first 24 hours

In view of the increasing number of very effective antibiotics now available the claims of any new antibiotic agent must be very critically examined before it is admitted into general clinical usage Tetracycline has at least justified further trial in that the incidence of side-effects appears to be less than that with the other substances of tetracycline series, and it seems to be quite as effective clinically

We wish to thank Dr T H Crozier and Dr J F Pantridge for access to patients under their care Prof G M Bull and Dr M G Nelson for helpful criticism and advice; and Mr H Cox for technical assistance The drug used was 250 mg capsules of Achromycin (tetracycline hydrochloride) provided by Dr A T Mennie of the Clinical Research Department of Messrs Lederle

M B Sydney
HOUSE PHYSICIAN

PRINCESS MARGARET HOSPITAL FOR CHILDREN PERTH
WESTERN AUSTRALIA

IT has long been known that meningo-encephalitis may complicate mumps yet its incidence does not seem to be fully appreciated

Patients with meningo-encephalitis usually present with headache vomiting pyrexia and signs of meningeal irritation There may be drowsiness, irritability and focal neurological signs, but the last are extremely rare The cerebrospinal fluid (C S F) shows pleocytosis and contains a normal or a slightly increased amount of protein and an invariably normal amount of sugar and chloride Mumps meningo encephalitis may precede accompany or follow mumps in other sites Occasionally it is the sole manifestation of mumps.

Present Investigation

We have recently studied 25 cases of meningo-encephalitis in a mumps epidemic We could not determine the incidence of this complication mumps not being notifiable in Western Australia but it has been variously reported—from 1·4% (Levison and Thordarson 1942) to 66% (Bang and Bang 1943) The figure given by Bang and Bang refers to the proportion in which there were changes in the C.S F whether or not there was clinical evidence of meningo-encephalitis Candel et al (1944) found in 38 cases of mumps 10 with manifest meningo-encephalitis and a further 20 with pleocytosis of the C S F Eberlein and Lynxwiler (1947) pointed out that mumps meningo-encephalitis could occur alone and found that in 36 of 280 cases no salivary glands were involved

Dunlop (1933) reported that the urinary excretion of diastase was increased in mumps and Candel and Wheelock (1940) showed that the serum-amylase level was raised in 215 of 224 cases of uncomplicated mumps Wolman et al (1947) reported similar results and thought that the serum amylase level did not rise in submandibular and sublingual mumps in the absence of parotitis

In the early phase of the recent epidemic the serum amylase levels were estimated in an attempt to determine the ætiology of meningo-encephalitis in the absence of enlargement of salivary glands The results obtained encouraged us to continue these studies on as many cases as possible

Criteria for Diagnosis

Our criteria for diagnosis were as follows

(1) A history of close contact with a case of mumps within a month of admission

(2) The onset of enlargement of a salivary gland less than fourteen days before or after admission

(3) Mild meningeal irritation in a child who was not very ill

(4) Sterile C S F with a raised cell count, due mainly to lymphocytes, either a normal or a moderately increased amount of protein, and a normal amount of sugar and chloride

(5) A raised serum amylase level was regarded as additional evidence in favour of mumps as the cause of the meningo encephalitis

5 cases satisfied 4 of the above criteria but did not have definite enlargement of a salivary gland These 5 cases have been included in this report

No facilities were available for isolation of the virus and for serological studies

In this series only children showing signs of meningeal irritation were subjected to lumbar puncture, which was done mainly to exclude the possibility of early pyogenic or tuberculous meningitis

Analysis of Cases

The patients were aged from 14 months to 12 years (see table) There were 21 boys and 4 girls, a finding which corresponds to the sex-distribution reported by Kilham (1949) (80% males), Birnberg (1939) (78% males), and Kravis et al (1951) (83% males)

Headache developed in all except 3 children aged more than 2 years, and vomiting in all but 1 (case 2) Convulsions were present in only 2 patients, 1 of these was an infant aged 20 months (case 2), and the other (case 20) a boy aged 9 years Neither had a history of fits

A history of recent enlargement of a salivary gland was obtained in 9 cases Clinical evidence of mumps was noted for the first time on admission in 5 children, and a further 6 developed typical mumps in hospital 5 children at no stage showed obvious involvement of the salivary glands

Abdominal pain was present in 9 children, of whom 5 had epigastric tenderness

The cell count of the C S F was 130–1100 per c mm, the percentage of lymphocytes being greater than 70 in all cases, and greater than 90 in most of them In only 3 cases was the C S F protein level above 100 mg per 100 ml, average values being 40–60 mg per 100 ml.

Serum-amylase levels were estimated in 20 cases * and found to be raised in 18, 5 of these 18 at no time had *convincing enlargement of a salivary gland* This investigation was made within three days of admission A raised level was still found in 3 cases ten days later

Only 2 children presented focal neurological signs case 4 had mild ataxia, which was still present on discharge seven days after admission, but had disappeared two weeks later, and case 19 developed retention of urine with overflow incontinence which required catheterisation for two days (on leaving hospital, however, his central nervous system was clinically normal)

The raised temperature returned to normal within seven days without treatment in all cases, and no child caused undue concern in hospital

Discussion

The mumps meningo encephalitis observed by us followed the typical benign pattern in the larger series observed by previous workers

Drowsiness was often present, but the patient's active coöperation was readily obtained Vomiting, which was often severe before admission, ceased rapidly in hospital

Lumbar puncture is strongly recommended in all children with signs of meningeal irritation, to exclude early or partially treated pyogenic meningitis A child aged 7 years, who presented a fairly typical history and clinical picture of mumps meningo encephalitis was found on lumbar puncture to have influenzal meningitis which had been treated with antibiotics for twenty four hours before admission In this connection it should be noted that 7 of the 25 cases had been treated with an antibiotic before coming to hospital

---

* The method used was based on that of Somogyi (193 0 1 ml plasma or serum was incubated with Somogyi's starch solution, the proteins were precipitated with 10% ZnSO₄ and 0 5*N* NaOH, and the glucose was estimated by the Hagedorn and Jensen blood sugar method (Harrison 1930) The normal range was considered to be 70–200 units The experimental error by this method is ±5%

It is difficult to assess the significance of abdominal pain present in 9 cases; this symptom is common to many pyrexial illnesses in children The possibility of a mild pancreatitis as the cause cannot be ignored

In 18 of 20 cases a raised serum amylase level was found despite the fact that 5 of the 18 had no definite enlargement of the salivary glands either before or after admission The mother of 1 of these 5 (case 17 aged 14 months) had typical mumps three weeks before the onset of her child s illness, and two other members of the family of case 7 developed mumps five days after his admission Wolman et al (1947) stated that, in their experience the serum amylase level did not rise in the absence of parotitis. Our findings do not substantiate this unless one postulates a subclinical parotitis The fact that the serum amylase level is often raised in mumps meningo encephalitis suggests that it may be of value in diagnosing mumps in the absence of the more usual manifestations and in differentiating it from other virus meningo encephalitides, of which the most important is non paralytic poliomyelitis Serological studies with S and V antibodies seldom reach diagnostic titres sufficiently early in the disease to be of great value and only a few laboratories have facilities for isolation of the virus

Summary

25 cases of mumps meningo-encephalitis are reviewed. In 5 of them no enlargement of a salivary gland was detected.

The sex-distribution was 21 males to 4 females

Mild meningeal irritation was invariably present and headache vomiting and fever were the most common associated features

The C.S.F showed pleocytosis and contained either a normal or an increased amount of protein

The serum amylase level was estimated in 20 cases and found to be raised in 18 in 5 of these there was no clinically detectable enlargement of the salivary glands

Serum amylase estimations may be of value in the differentiation of this condition from non paralytic poliomyelitis.

There were no deaths and no sequelæ.

We wish to thank Dr W Seed Dr N Barsden Dr C Lankester and Dr J Watson for permission to publish details of their cases and Miss M McRae for the biochemical investigations.

ADDENDUM

Since submitting this article we have seen 9 additional cases of mumps meningo-encephalitis In 3 of these there was no swelling of the salivary glands and in each the serum amylase level was raised Of the remaining 6 patients 5 had raised levels

Reviews of Books

Pharmacology in Medicine

A Collaborative Textbook Editor VICTOR A DRILL, PH D M.D lecturer in pharmacology Northwestern University Medical School New York and London McGraw Hill 1954 87 sections £7 10s

THIS massive volume looks like the book to end books in the world of pharmacology Each chapter, says the editor has its own numbering of pages and illustrations This he claims, will simplify the editing of future editions and he might have added that it also foxes students and reviewers who share a morbid interest in the number of pages in a book Suffice it to say that Drill weighs 6½ lb which is fair enough for a first-delivery

The reader is introduced easily via physiological considerations, to pharmacology and later to therapeutic applications The ramifications of pharmacology are revealed by substantial contributions on water and salt balance allergic manifestations oral and intravenous feeding and lipid metabolism The text is enlivened here and there with clinical case reports and it is lavishly furnished with references which have a strong American flavour Though comprehensive the book is readable which reflects credit both on the editor and his collaborators The needs of the student and practitioner of medicine are kept constantly in mind only occasionally does the pure pharmacologist take the stage and demonstrate (as some wag has said) not rabbits out of a hat but habits out of a rat The mature student who has learnt to dip judiciously into larger books to supplement his reading will find this volume stimulating but in view of the price most will have to consult it in a library

The book is not faultless in minor matters. The definition of therapeutics— the use of drugs in the treatment or prevention of disease —disregards etymology and gives a much too limited view of the scope of medical care There are some typographical errors, and the attempt using diagrams to equate blood-alcohol levels and their medicolegal significance is an example of over-simplification of a biological problem It fails—as the contributor writing the article is well aware—because it does not take into account the varying susceptibility of the drinkers Philologists will be pained by a reference to " the English slang O.K.

Notwithstanding these small criticisms, this book represents a notable contribution to clinical pharmacology and a milestone in the art of medical editorship

Modern Trends in Blood Diseases

Editor JOHN F WILKINSON M D M.SC PH D F R C P F R.I C. director of the department of hæmatology Manchester Royal Infirmary London: Butterworth 1955 Pp 359 65s

AUTHORS in this series are actually engaged in the work written about and are encouraged to state their own views and results rather than to attempt a comprehensive review of published work Most of those contributing to this volume have produced readable essays and deadly summaries with rows of references have been avoided by almost all The editor has naturally gathered contributions from his colleagues in Manchester but he has not limited himself to Manchester or even to this country and there are three first-class transatlantic contributions

D Ll Griffiths has an original and very well illustrated chapter on bone changes in blood-diseases. M C G Israëls gives a succinct account of his ideas on the classification and treatment of reticuloses, and a well reproduced colour plate shows histological and blood changes The chapter on skin changes in blood-diseases by J H. Twiston Davies collects together a lot of scattered and much new information and the same can be said about D B H Dawson s chapter on changes in the fundus in blood diseases F Stratton has an interesting chapter on the occurrence detection, and avoidance of iso-immunisation to blood group antigens, including all the newer groups The chapter on hæmolytic anæmia by Crosby and Dameshek is a remarkably clear thoughtful and concise account of our present knowledge of this difficult group. Carl Moore and R Dubach compress into 25 pages an account of how our ideas on iron metabolism have been changed by using *radioactive iron*, and Cartwright and Wintrobe give a notable account of their researches into iron, copper, and porphyrin metabolism in the anæmias that accompany infections W F Gaisford, writing on hæmatology in childrens' diseases, C Rimington on pigments and porphyrins, and C C Ungley on vitamin B_{12} and megaloblastic anæmia, survey their respective fields Alexander Brown gives a short account of anticoagulant therapy, its indications, its control, and the drugs to use, this is the only contribution in the field of blood clotting studies, perhaps because comprehensive accounts of present researches and ideas have been published only recently Finally, the editor and his co workers deal with the treatment of chronic and acute leukæmias in two chapters which, despite the inevitable delays of book production, are notably up to date

Anyone contemplating research on any of these subjects should read the relevant chapter first, the contents list shows how much of interest there is for specialists in other fields too

Advances in Virus Research

Vol II Editors KENNETH M SMITH, virus research unit, Molteno Institute, Cambridge, MAX A LAUFFER, department of biophysics, University of Pittsburgh, Pennsylvania New York and London, Academic Press 1954 Pp 312 $7 00

THE editors point out that their second instalment needs to be taken with volume I for a proper balance Certainly volume II wears a much more physicochemical look than its predecessor, and one or two of the articles are written by the initiated for the initiated

There is, however, an extremely fine assessment of electron microscopy of viruses, by R C Williams Electron microscopy has been called the science of artefacts, and Williams's article, written with a biological slant, is a careful attempt to separate the facts from the artefacts W W Ackermann and T Francis write about viral development in tissue cultures, mainly an account of the interesting work from their own laboratory on the effects of various chemical inhibitors on different stages of viral development within cells P von Magnus's chapter on incomplete forms of influenza virus is incomplete in some respects C A Knight gives a very useful review of the chemical constitution of viruses, with pride of place to the plant viruses F O Holmes and F C Bawden discuss plant diseases and inheritance of resistance to viral diseases in plants and inhibitors E Pollard and M A Lauffer and I J Bendet deal with the action of ionising radiation on viruses and the hydration of viruses respectively

The new volume contains less about animal or bacterial viruses than some readers would like, but no doubt the balance will be restored in volume III

Die Tests in der klinischen Psychologie

Erster Halbband Editor Prof Dr ERICH STERN Zürich Rascher 1954 Pp 418 Sw Fr 28 10

DURING the last twenty years there has been a comparative dearth of original work and publications on psychological tests in the non-English-speaking countries In his introductory chapter Professor Stern, editor and chief contributor of this volume, comes to the conclusion that clinical psychology requires the use not only of tests but also of history-taking, clinical observation, and interviews

His exposition and that of several other contributors shows a medical bias which perhaps accounts for the weak technical treatment of test procedures and their validation By modern standards, many of the chapters are superficial on this point, though informative about the empirical use of the tests Other chapters are, however, sophisticated—e g, Hathaway and Meehl's brief account of the Minnesota personality inventory After a general review of history and problems, there are a number of chapters on intelligence and performance tests, the development of children, the study of motor behaviour, and statistical methods, including factorial analysis The second half of the book describes personality tests, especially the M M P I, Eysenck's attitude inventory, Jung s association tests, and the procedures of Szondi, Mira, and Tramer In a second volume (which it is promised will contain the index which the reader lacks when consulting this volume) further personality tests will be considered as well as vocational tests. The two volumes are to be the opening portion of a system of clinical psychology, edited by Professor Stern. It may be predicted that it will be to a large extent a system of psychological medicine

Surgery of the Small and Large Intestine

CHARLES W MAYO, M D, section of surgery, Mayo Clinic, Rochester, Minnesota Chicago Year Book Publishers London Interscience Publishers 1955 Pp 340 68s

"INTESTINAL surgery without tears," might be the subtitle, since this work is concerned with operative technique portrayed by line drawings facing almost every page of text It is not a profound work, being written by the practical man for the less practised man the author explains in the preface that it is no part of his task to refer to the literature

Details of technique are occasionally expanded with words of advice and general experience, not without charm "My father remarked long ago that, except for resection, one should avoid touching the intestine affected with ulcerative colitis just as one would avoid touching the roof of an old tent without a fly in a rainstorm" In general the advice is sound though some eyebrows will be raised at the statement that for intussusception, whether reducible or not at the time of operation, resection is as a rule indicated because of the tendency of the condition to recur There is a useful preliminary chapter on diets, and another on methods of intestinal anastomosis, it is good to find the author advocating not only end to-end anastomoses, even when ileocolic, but also the open technique

---

Diseases of the Nervous System (8th ed Edinburgh and London E & S Livingstone 1955 Pp 357 24s)—Sir Francis Walshe, F R S, has had the satisfaction, in the eighth edition of his widely used textbook, of shortening the chapter on neurosyphilis—once the most prominent cause of disorders of the nervous system He has always taken the opportunity offered by new editions to examine much that is new, and—of necessity—some that is ephemeral, for, as he says in his latest preface, only thus can an author fulfil his responsibility for stimulating the critical thinking of his readers

Diseases of Infancy and Childhood (7th ed London J & A Churchill 1955 Pp 804 50s)—In Dr Wilfrid Sheldon's well known book, interesting signs of the times are the omission of the section on wet nursing and the cautious but partial approval of demand feeding—contrasting with the uncompromising adherence of previous editions to rigid feeding schedules The author's strong views on the toilet training of infants will not meet with everyone's approval The omission of the section on flatulence and colic from the chapter on digestive disorders of infancy is curious, for infantile colic remains as common and troublesome as ever and it has been much discussed in recent years There are fewer prescriptions in the new edition now that many more specific remedies are available, and the appendices on dosage of drugs and on sulphonamide and antibiotic therapy have been removed. There are many new illustrations mainly of excellent quality, but one or two of the older blocks are getting just a trifle worn Despite much new material this edition is eight pages shorter than its predecessor Students will find it as good a friend as ever

Human Adrenal Cortex.—Volume VIII in the Ciba Foundation Colloquia on Endocrinology reports the proceedings of the conference on this subject held at the foundation last year in two parts The first, under the chairmanship of G Pincus, covered histological and biochemical aspects and corticomedullary relationships, the second, under the chairmanship of G W Thorn, dealt with physiological and pathological aspects and with hypothalamic and pituitary relationships The editors of the volume are Dr G E W Wolstenholme and Miss Margaret Cameron (London J & A Churchill 1955 Pp 665 55s)

Gestation—The Josiah Macy, jun., Foundation New York, has published the transactions of the conference on this subject held in March, 1954 The editor is Prof Louis B Flexner, M D (1955 Pp 238 $5)

THE LANCET

LONDON SATURDAY MAY 28, 1955

Surgical Treatment of Parkinsonism

THE search for effective measures to control parkinsonism continues The latest operation involves occlusion of the anterior choroid artery [1 2]—a measure suggested by relief of tremor and rigidity in a patient with parkinsonism after accidental tearing of this artery during the approach to cerebral pedunculotomy COOPER [2] has occluded the vessel by clips and diathermy through a subtemporal approach In 30 such operations the mortality was 13% Apparently the most constant effect is relief of rigidity which is striking Moreover in 9 of the 11 postencephalitic cases tremor has been eliminated or materially lessened for periods of, so far, up to a year In these first 30 cases there have been only 2 instances of postoperative hemiplegia due apparently to an effect on the middle cerebral artery, and there have been 3 instances of transient palsy of the oculomotor nerve The postencephalitic group did best of all Neither of the 2 arteriosclerotic cases which were operated on survived.

The introduction of this operation has given rise to a good deal of discussion about the anatomical distribution of the anterior choroid artery and the accuracy of efforts to occlude it ABBIE [3] had previously drawn attention to variations in the course and distribution of the artery and to its anastomosis with the posterior choroid vessels and CARPENTER et al [4] have now found from necropsy studies that in only just over three quarters of 60 dissections did the artery arise from the internal carotid artery They confirm that it is usually the first branch to be given off after the posterior communicating artery, but in 10% of cases other lenticulostriate vessels intervened Moreover the branches of the anterior choroid artery itself varied in their origin, and in half the cases the first branch arose 5–10 mm along the parent trunk Thus it may be difficult to ensure that the anterior choroid artery is the one that is clipped, and even when, as COOPER recommends, diathermy is applied along the artery in order to prevent collateral circulation the blood supply to the globus pallidus may remain intact COOPER has done bilateral angiography before operation in order to determine the position of the vessels, but this method is unlikely always to show these fine vessels with sufficient accuracy The anterior choroid artery may have a wide area of distribution but all the evidence suggests that it constantly supplies the globus pallidus and the presumed rationale of the operation is that it produces ischæmia or infarction of this structure In this series there was no example of a visual field defect or hemiplegia resulting from occlusion of this vessel. But in the clinical syndrome of occlusion of the artery [3] hemiplegia is constant from impairment of the blood supply to part of the posterior limb of the internal capsule, and a field defect is common from involvement of the blood supply to the optic tract or radiation or the lateral geniculate body This adds to the difficulty of accepting the explanation of the operative results, unless one assumes that the globus pallidus has a relatively poor blood-supply or that in a diseased state it is particularly vulnerable to partial ischæmia.

Nor are the uncertainties only anatomical The exact mechanism of the rigidity and the tremor is far from clear—as is shown by the variety of the surgical approaches On the one hand some assume that these disturbances result from disordered function of the globus pallidus, and this may be countered by destroying it through interference with its blood supply (COOPER's operation) by direct electrocoagulation using stereotaxic procedures,[5–7] or by division of its efferent-fibre connections with the thalamus through section of the ansa lenticularis and fasciculus lenticularis [8] and NARABAYASHI and OKUMA [9] report from Japan excellent results from injecting procaine in oil into the globus pallidus Others, on the other hand believe that the movements must originate in the motor cortex and seek to relieve tremor by excising part of this cortex or by interfering with the motor projection, at the cost of hemiparesis Excision of the motor area [10] partial division of the anterior limb of the internal capsule [11] cerebral pedunculotomy,[12] and cordotomy [13–15] are all practised, although rigidity may be little relieved and may even be accentuated There is a third approach Some patients with parkinsonism are much worse under emotional stress and OLIVER [15] has helped some of these patients by selective frontal leucotomy (undercutting areas 6 8, 9) Apparently similar results in the wider field of motor disturbances are being obtained by TAKEBAYASHI [16] BROWDER has drawn attention to frontal lobe symptoms after his capsule operation, and we do not know enough of the connections of the corpus striatum to exclude indirect frontal lobe effects from operations directed at the globus pallidus.

The usefulness of surgery in parkinsonism is necessarily limited for the results are best in the younger patients, and in those where the symptoms are predominantly unilateral and the signs more or less stationary whereas usually the disorder affects older people and is bilateral and progressive For a year or so after most of these operations the patient may benefit by having exchanged tremor for hemiparesis, but later on when the disease has progressed, the sequelæ of the operation are apt to become an added disability COOPER's operation on the anterior choroid artery is especially interesting because it apparently relieves rigidity as well as tremor, and because it may

be applicable to bilateral cases Electrocoagulation of the globus pallidus by means of stereotaxis also has these potentialities, but this method is likely to be used in only a few highly specialised centres

As long as our knowledge of the basic anatomy, physiology, and pathology remains incomplete, firm conclusions on the rôle of surgery will be difficult to make But undoubtedly many patients have been helped by one or other of these operations

Children in Hospital

For better or worse we are competitive animals, goaded to our best efforts chiefly by observing the achievements of others Thus it is an important duty, in any discipline, to see—or, failing that, to hear—how the other fellow does it Young children, admitted to hospital, are so prone to suffer a setback in their emotional development that people in many countries are now seeking to prepare them for, or protect them from, the risks of this particular experience, but attempts have been scattered and piecemeal, and it has not always been easy, or perhaps even possible, for those who minister to a child's physical needs in hospital to pay more than lip service to the requirements of his psyche A study group of the World Health Organisation have been examining the problem, and an account of their findings, by Dr Mary Capes,[1] has now appeared The group was composed of distinguished physicians, pædiatricians, and psychiatrists from the United States and fourteen European countries, and the report shows how remarkably the outlook in these various countries differs, even though they all have a common tradition

The members of the group agreed—as most others will—that a sick child is usually best off in his own home, and that many more children could be treated there if some additional services were provided to help the parents In some countries, our own among them, both parents may go out to work, and a child may be admitted to hospital for this reason alone The group suggested that firms employing women should maintain a relief staff, who could take over the work of a mother absent because of the sickness of a child They also thought that the mother should receive sickness benefit for the child equivalent to the wages lost, so that she would not be tempted to put her job before her child Sometimes a child who is making little progress as an outpatient is admitted by the pædiatrician merely because he is at a loss what to do next He should make it clear—at all events to himself—why he wants the child in and what investigations he intends to do, and he should be convinced of what the study group called "the unconditional necessity" of the step In some countries—or rather at some hospitals in some countries—thought is being given to preparing the child for admission This is not an easy thing to do, especially with children below the age of 4 or 5, for they often take what is happening to them to be a punishment, and accept with terror the idea that their parents have rejected them A young child, unless his physical condition compels it, should never be sent into hospital just before or just after the birth of his successor in the family Emergencies are a different matter then the parents as well as the child need emotional support, and they should be allowed to stay near the child and, particularly, to be with him when he comes round from an anæsthetic In some hospitals the pædiatric department has a playroom, staffed with "play nurses", and here the convalescent child can "play out" his experiences and so reduce the anxiety they have provoked In some hospitals parents are given a booklet advising them on the way to prepare their children for admission, and in others—including some in this country and in New Zealand—the mother is admitted with the child, and not only keeps him company throughout his stay, but does all her usual services for him, and even, under guidance, all his dressings The benefits obtained from this practice by Cecily M Pickerill and H P Pickerill[2] in New Zealand have not been psychological only nursing by the mother has also cut out *all* cross infection in a hospital engaged in plastic repairs of hare lip and other developmental anomalies

There are some pædiatricians—and some parents too, the group report—who believe that in a hard world children should be toughened from birth onwards Some hospitals, too, take the view that it is not much use worrying about the effects of hospital experiences on children so long as there are child psychiatrists and child-guidance clinics to look after casualties, they must just take their chance The need for prevention of such casualties is thus evaded, not merely because of the pressure of clinical work but almost as a matter of policy A wasteful policy, surely, for though no-one can live his life without experiencing difficulties and struggling to overcome them, the initial tolerance of young children to such stresses is low, and, as the study-group say, the dosage must be graded if they are to avoid permanent damage Hence they emphasise the importance of the mother's presence when the child is in hospital she is the most effective prophylactic we have against psychic trauma, because she provides the normal emotional environment of the child

Physical environment, too, deserves some thought The group pointed out the drawbacks of both old high wards and new glass cubicles ("conveying the impression of a refrigerator")—though they recognised, of course, the value of isolation. The wards, they say, should be small, with a cot like the one the child is used to at home, and "with furnishings he will appreciate", and he should not, at the moment of admission, be deprived of his toy from home or his own clothing At no stage should he be subjected to routine procedures which are not really necessary, or alarmed by syringes and preoperative enemas, or allowed to get to the anæsthetic room in a state of frightened awareness

Among unnecessary routine procedures must be classed the too rigorous limitation of visitors The group noted that in Italy, where people are traditionally warm-hearted to children, visiting has never been forbidden, and the only exceptions made are in cases where visiting seems likely to cause serious harm to the child In East Africa the child's mother, or some other relative, and indeed often his whole family, camp at his bedside day and night, and the main difficulty is to prevent the mother from taking the child out of bed to sleep beside her on the floor, or from getting into bed beside him The member

[2] *Lancet*, 1954, i, 425 see *Ibid* p 447

the study group who reported thus found it had given him food for thought, for there appeared to be less evidence among these children of psychological disturbance Though no statistics are available to show whether in fact they do have less psychological trauma as a result of the upheaval than do European children, the possibility is interesting The group note that ' there are still many children s hospitals in a number of countries where visiting is forbidden, and many others where it is grudgingly permitted once weekly or even less '—no doubt because the fear of cross infection has been magnified out of proportion to its importance The British Pædiatric Association in 1945 analysed data collected in twelve different centres and concluded that there was no positive evidence that visiting *by adults* increased infection it is the presence of other children which introduces risks Children making a long stay in hospitals or institutions are specially prone to suffer an arrest in emotional development and many of the group felt that parents should be allowed travelling expenses to visit such hospitals especially those remote from towns Children in such long stay wards who never get visited suffer bitterly and should be a special concern of the pædiatrician and nurses Where there are play nurses on the staff they can be encouraged to spend extra time with such lonely children

The group gave much thought to the training of staff for children s departments how far should the pædiatrician be a psychiatrist, or the psychiatrist a pædiatrician, and how far should the nurse be familiar with the work of both ? An extensive course offered in his university was described by one of the members Dr M J E SENN professor of pædiatrics and psychiatry at Yale

> The emphasis is on growth and development behaviour and the parent-child relationship A pædiatric residency lasts two to three years, and one method used is to introduce the young pædiatrician to life outside the hospital : each intern on starting follows the last three months of pregnancy in a woman who agrees to accept him as her pædiatrician He gets to know the family witnesses the birth sees the mother's response to labour and to the child meets both in the well baby clinic, and is called into the home if at any time the child falls ill He works under an assistant resident and if special problems arise can call in a senior member of the staff in consultation At case-conferences, attended by the whole staff patterns of growth in behaviour in the children attending the department are discussed The aim is always to bring out the mental as well as the physical aspect of each case

Similar training schemes were reported from a few other countries and the group thought the principle sound They recommended that pædiatricians should be trained in those children s hospitals where it is possible for them to work with a psychiatric team , or failing that should spend at least a year in a child guidance clinic Similarly they felt that the child psychiatrist should have carefully planned training in pædiatrics They took a serious interest, too in the training of the pædiatric nurse and here again the experience of Yale was illuminating In addition to lectures and discussion groups on pædiatrics and the physical care of children, nurses too are taught growth and development as part of their practical training Thus they spend two weeks in a nursery school and two weeks as a ' play nurse working with a full time ' play worker in the wards They join the medical rounds and are encouraged, as members of the team, to ask questions , and they attend a weekly conference of student and graduate nurses with the pædiatrician They are also warned of the stresses and pitfalls of their job—the risks of becoming too possessive, of resenting the real mother, and of becoming impatient with a child who regresses to behaviour patterns too young for his age

The W H O report is a plea for close collaboration between the pædiatric and the psychiatric teams only by working together can they arrive at a balanced diagnosis, and so plan treatment to protect and heal the whole child

Annotations

GENETIC FACTORS IN EPILEPSY

EPILEPSY is not an easy subject for genetic study fits can be caused in many different ways and it is difficult to decide which of several possible factors is at work In the last few years each of the more obvious lines of approach has been carefully explored Alström[1] divided his index cases according to whether the ætiology was known probably known or unknown He found no striking differences between the risks to the relatives in each of these three groups But as Alström says

> It is never possible to determine the causal connection other than with varying degrees of probability

Harvald[2] following Lennox[3] divided his index cases by their electro encephalograms He was fully conscious of the limitations of this method but all the same found it gave some interesting results Ounsted[4] working entirely on children, has classified his index cases purely by their clinical features and then noted the groupings suggested by the pattern of fits in the near relations

Excluding all cases of infantile convulsions alone, Harvald found, in common with earlier workers that the risk to first-degree relations of developing epilepsy was from $2^1/_2$ to $4^1/_2$% The risk was less when the electro encephalogram of the index case was normal or near normal than when it was definitely abnormal This was true whether the abnormality was of the 3 per second ' spike and wave pattern or of the 3 per second paroxysmal pattern or showed a well-defined focus He found like Lennox that the electro-encephalograms of the relations were much more often abnormal than were their clinical histories and that the abnormality tended to be of the same type as that of the index case The exception to this was that the relations of index cases with focal abnormalities in the electro-encephalogram showed no increase in abnormal electro encephalograms of any kind even though they had an increased incidence of epilepsy He also found that ' carriers who had probably transmitted epilepsy though themselves unaffected, often had normal electro-encephalograms Harvald suggests that a tendency to cerebral paroxysms and a tendency for these paroxysms to develop into fits are inherited independently and that several genes are concerned

Only a preliminary report of Ounsted s very extensive survey of children in the Oxford district has so far been published His purely clinical approach has much to commend it He included among his index cases all children who had had convulsions of any kind and divided them in the following way remittent febrile convulsions febrile convulsions continuing until death febrile convulsions associated with a brain infection, epilepsies which remit epilepsies which resist treat ment and persist, febrile convulsions which are followed by epilepsy which then remits, febrile convulsions which are followed by persistent epilepsy, and a mixed group of other convulsive disorders such as anæsthetic seizures. Any convulsions among the brothers and sisters of the index cases were classified in the same way, and so in each group there was drawn a family pattern of convulsions of the different types. In this way the group of index cases with remittent febrile convulsions, remittent epilepsy, and convulsions followed by remittent epilepsy were found to have much the same family pattern. The sibs showed a high incidence (17–25%) of convulsions of all types, most of these being remittent convulsions and about a third epilepsy. The epilepsy was most often remittent epilepsy, or convulsions followed by remittent epilepsy. The sibs of the index cases with continuing epilepsy showed about the same amount of convulsions of all kinds and of epilepsy (9%) but the epilepsy here in most instances was continuing and resistant to treatment, like that of the index case. In contrast to both these was a family pattern found with convulsions associated with brain infection, encephalitis, or meningitis. Here the sibs had an incidence of convulsions of all sorts of 6% and of epilepsy of only 2%; most of the epilepsy was of the continuing type. This pattern may well be that of any random sample of children. Thum [5] did in fact find an incidence of 6% of convulsions in a group of over three thousand children in Boston, Massachusetts. Two other groups were of special interest. First, the group of children in whom the convulsions went on continually until they died might perhaps be expected to behave like the group with brain infections; but the incidence of convulsions of all sorts in the sibs was nearly 30% and the incidence of epilepsy nearly 17%, most of this epilepsy being of the continuous type resistant to treatment. The other group of special interest were the children with temporal lobe attacks, often assumed to be purely symptomatic. Here the family pattern was very much that of groups where the index cases had remittent febrile convulsions or remittent epilepsy, with 15% of convulsions of all sorts and 6½% of epilepsy, most of which was remittent epilepsy. Genetic endowment would appear to play a part here too. This has of course no direct bearing on the value of surgery for this disease.

[2] Harvald B Heredity in Epilepsy Copenhagen 1954
[3] Lennox W G Amer J Psychiat 1947 103 457
[4] Ounsted C Eugen Rev 1955 47 33

A possible interpretation of these findings in children is that one genetic factor or group of factors predisposes to remittent febrile convulsions or remittent epilepsy, or sometimes temporal lobe epilepsy; while another factor or group of factors predisposes to persistent epilepsy resistant to treatment but sometimes results only in remittent febrile convulsions. Febrile convulsions continuing till death would then appear to be due to an intense form of the second group of factors.

NEW STEROIDS

COMPARATIVELY minor alterations in structure can profoundly change the pharmacological characteristics of a steroid hormone. Thus a halogenated derivative of hydrocortisone, 9α-fluorohydrocortisone, exerts a much greater anti-inflammatory action, weight for weight, than hydrocortisone, and in terms of mineralocorticoid activity it is proportionately even more potent. Because it readily brings about sodium retention, this compound is unsuitable for use in the treatment of rheumatoid arthritis.[6] There would be an obvious place for substances suppressing inflammation without inducing sodium retention; and it has been claimed that two new synthetic steroids—metacortandralone and metacortandracin—meet this need.

Bunim et al.[7] found from the administration of metacortandralone to seven patients with rheumatoid arthritis that it was three to four times more potent than cortisone, and two to three times more potent than hydrocortisone. Effects on the clinical picture, the erythrocyte sedimentation rate, and C-reactive protein were similar to those of cortisone. With doses which effectively suppressed the signs of active arthritis, there was no sodium retention or potassium loss. With rather higher doses a negative nitrogen balance developed. The steroid did not raise the fasting level of blood sugar, and in no case did glycosuria appear. The undesirable effects, described as minor, included manifestations of Cushing's disease seen in some patients treated with cortisone—hirsutism, facial rounding, acne—and also sleeplessness and transitory mental depression. Hypertension did not develop. The properties of metacortandracin were very similar. Bunim and his colleagues emphasise that there is still no information about the effects of long-continued administration of these new steroids.

Metacortandralone and metacortandracin may prove useful in cases where cortisone produces excessive sodium retention. But probably many of the limitations of cortisone are shared by these new derivatives—there is, for example, little reason to hope that in rheumatoid arthritis they will arrest damage to the joints any more effectively. In further trials the suppressive effect of these derivatives on the adrenal cortex will have to be assessed.

DEFORMITY OF THE PYLORIC ANTRUM

THE most important cause of persistent deformity of the pyloric antrum is carcinoma; but benign lesions of the stomach or duodenum or, occasionally, extrinsic causes can give rise to very similar radiographic appearances. Balint and Slater [1] point out that no single diagnostic measure—clinical examination, radiography, gastroscopy, or even laparotomy—can be relied on to distinguish the benign from the malignant lesion. Gastroscopy and radiography are complementary methods of examination [2]; some, such as Flood and Hennig [3] emphasise the limitations of gastroscopy but others have found it very reliable. Radiography is the simplest method of demonstrating antral deformities, but its value depends very largely on the individual radiologist. Even in expert hands, it does not always reveal clearly whether an ulcer is benign or malignant.

Allen and Welch [4] estimate that of all prepyloric ulcers 75% are malignant; but Ransom [5] found that in his series some 90% were benign. The gastric ulcer—particularly at the antrum—that shows no signs of healing despite clinical improvement should be regarded as possibly malignant. On the other hand, apparent healing does not exclude malignancy. Gastric analysis may be helpful, in that the absence of free hydrochloric acid is commoner in carcinoma than in benign lesions; but gastric carcinoma can exist in the presence of hyperchlorhydria.[6]

In some cases of antral deformity no cause can be demonstrated.[1] Flood and Hennig studied 42 cases of "benign antral disease," in 9 of which no evidence of ulcer was brought to light. Possibly the deformity is sometimes due to true antral gastritis, and in one of the cases reported by Balint and Slater there was histological evidence of "chronic gastritis"; but many radiologists hesitate to make such a diagnosis, particularly since it is commonly not easy to confirm. Possibly, as Balint and Slater suggest, in other cases the deformity is the outcome of recurrent peptic ulceration with persistent spasm or residual scarring of the antrum; and occasionally per tent spasm develops in the apparent absence of any al disease [7]

When the radiographic or gastroscopic appearances are onclusive, laparotomy is preferable to a policy of it and-see But laparotomy also has its limitations ulcer or early malignant infiltration is not always tectable and a malignant ulcer may appear benign d an inflammatory mass around the duodenum lignant[7] so sometimes the diagnosis can be ablished only by microscopic examination

ADENOSINE AND THE HEART

Drury in 1936[8] described detailed studies of the tion of adenosine derivatives on the heart in small imals The main effect was on the conducting system th sinus slowing and auriculoventricular block. Green d Stoner[9] found that these compounds also caused a nsient fall in blood pressure Honey et al[10] showed at adenosine could produce heart block in healthy n The effect of magnesium adenosine triphosphate the electrocardiogram (E.C.G.) was extensively studied Wayne Goodwin and Stoner[11] in patients who were ceiving intravenous injections of this substance as eatment for rheumatoid arthritis When the injection s made rapidly there was invariably subjective dis rbance consisting of hyperpnœa, cough, flushing and transient sensation of faintness In all cases the blood essure fell the greatest reduction being by 100 mm. Hg e changes in the E C G were remarkably constant nall doses (5–15 mg) produced brief sinus bradycardia llowed by sinus tachycardia Larger doses (15–30 mg) used pronounced sinus slowing, and in addition pressed the conducting tissues with consequent first second degree auriculoventricular block, Wenckebach riods and occasionally complete asystole for several conds The action of adenosine was similar to that of enosine triphosphate but less distinct The production auriculoventricular block by adenosine triphosphate as prevented by atropine indicating that this action as mediated through the vagus Adrenaline produced similar effect to atropine The action of adenosine iphosphate on the heart was not confined to the nducting tissues ; alteration in the ST segment and entricular ectopic contractions suggested a direct effect n the myocardium. These myocardial effects were found be decreased by the magnesium ion which potentiated e depressant action on the conducting system

Adenosine triphosphate also brings about dilatation of he coronary arteries in animals[12] and various forms of denosine have been used from time to time in the reatment of cardiac and peripheral vascular disease Vayne Goodwin and Stoner[11] considered that use of his substance for such purposes might be unwise in iew of the direct effects on the myocardium while Honey et al[10] did not regard adenosine as useful for he treatment of heart-disease In a letter on p 1125 r Somló describes the treatment of supraventricular aroxysmal tachycardia by rapid intravenous injection adenosine triphosphate 20 mg Both the subjective ffects and the E.C.G changes were essentially similar to hose described previously, except that there was nvariably ventricular asystole sometimes followed by ultifocal ventricular ectopic beats which in turn were ollowed by normal beats and then by normal sinus ythm There were no untoward side-effects

Adenosine triphosphate may prove a powerful thera utic weapon against paroxysmal tachycardia But it ould be remembered that supraventricular tachycardia is often a benign condition which is a nuisance rather than a danger and that attacks commonly terminate *spontaneously Most physicians therefore prefer first* to try simple measures such as carotid pressure or trick manœuvres to induce vagal stimulation sedation or oral administration of digitalis But not all cases respond to such treatment and long-continued paroxysmal tachycardia may constitute a real danger to the patient In such circumstances adenosine triphosphate might certainly be considered and this drug may be more effective than others such as methacholine chloride quinidine or procainamide, which are not uncommonly used Adenosine triphosphate might with advantage be given as the magnesium salt which has less direct action on the myocardium.[11] In view of its action on the myocardium, great caution is necessary in administering it to patients with organic heart disease and much cardiac enlargement but need to terminate the ectopic rhythm may justify the risks. Adenosine triphosphate should not be given without E C.G control and preferably atropine should be at hand in case prolonged asystole ensues It seems possible from Somló s observations that adenosine triphosphate might induce ventricular tachycardia but this has apparently not arisen on any of over four hundred occasions referred to by Dr Somló when the drug was administered to terminate a supraventricular paroxysm of tachycardia

Somló considers that the response of supraventricular tachycardia to adenosine triphosphate is so specific as to constitute a diagnostic criterion But of course as he would no doubt agree, the diagnosis should be established clinically and electrocardiographically before the drug is administered

A SNOW CENTENARY

EPIDEMIOLOGISTS have been accused of having a Broad Street Pump fixation which blinds them to the needs and opportunities of work on diseases of more immediate importance than cholera Quite unabashed, the section of epidemiology and preventive medicine of the Royal Society of Medicine met on May 17 at the London School of Hygiene and Tropical Medicine to celebrate the centenary of the publication of Dr John Snow s classic *On the Mode of Communication of Cholera* A group of students working for the diploma in public health had prepared an exhibition (which will be open for a month) of Snow miscellania ranging from a hitherto little-known portrait painted at the request of Queen Victoria to an account of the findings at necropsy after his tragically premature death from chronic renal disease at the age of forty five The exhibits outline the main facts of his life and the steps which led him to record his belief that cholera was spread through infection of the community s drinking water by the patients dejecta first rather tentatively in 1849 and then with forceful conviction in the more substantial edition of 1855 This book which as Wade Hampton Frost said in his introduction to the Commonwealth Fund reissue should be read once as a story of exploration and many times as a lesson in epidemiology is indeed the exemplar of the epidemiological method at its best

Prof A Bradford Hill F R.S the section s president pointed out that Snow had to wait for confirmation of his thesis until the disastrous epidemics of the 1850s when the removal of the intake of water supplied by the Lambeth Company up the Thames to Ditton produced the remarkable contrast in cholera mortality which formed the basis of Snow s experiment on the grandest scale In Southern London the pipes of both the Lambeth Company and the Southwark and Vauxhall Company (which drew the filthiest stuff ever drunk by a civilised community from the Thames in the heart of the city) went down every street supplying rich and poor clean and dirty in a manner which had all the

appearances of random allocation Yet, as Snow found out by arduous "shoe leather epidemiology," the absolute number of deaths in the houses supplied by the Southwark and Vauxhall Company was vastly greater than among the customers of the other Unfortunately, he did not then know the number of houses supplied by each company in the area, and could not give his dramatic contrast the rigorous basis which only comparable rates provide, until a year after the publication of this main work Meanwhile, the epidemic centred round the pump in what is now Broadwick Street had exploded with appalling results Within three days over three hundred people were dead from cholera The dramatic account of Snow's discovery of the focal importance of the pump and his appearance before the local vestry to recommend the removal of the pump-handle is well known But Snow himself shunned the facile argument that the epidemic was thereby halted, and indeed he pointed out that the panic stricken flight of the inhabitants had already done that by what would now be called "the exhaustion of susceptibles"

The removal of the pump handle was thus symbolic rather than effective, signalling the beginning of the end of cholera as an epidemic disease in this country That that end was not at once achieved is a sad reflection on the scientific and moral climate of the times For, as a contribution from Prof James Mackintosh reminded the meeting, much of England's prosperity in the reign of Queen Victoria was illusory and its morality superficial The local vestry dealing with the Broad Street epidemic was rebuffed by Sir Benjamin Hall, and for years after the outbreak Lankester, Snow's helper and friend, protested forcibly against the failure to close the surface water pumps in the district Snow's views were attacked in the *Times* by the secretary of the Private Enterprise Association, whose disinterested ness was clearly suspect, but even within the profession his ideas received little encouragement Men of manifest good will, such as Simon, were so overwhelmed by Chadwick's *Report on the Sanitary Condition of the Labouring Population* that they were unable to conceive of a specific agent of disease other than the vague miasmata rising from filthy environment With shame we acknowledge that *The Lancet* accused Snow of riding a scientific hobby-horse by insisting on the paramount dangers of the sewer Despite his solitary abstemious habits and his lack of eloquence, Snow, by the weight of his circumstantial evidence, eventually had his views generally accepted So today we join in honouring the work of a man who rid his country of cholera, not by technical innovation, but by courageous application, acute observation, and an inspired and logical arithmetic

HEAD INJURIES IN AMATEUR BOXING

IT has been estimated[1] that after five years' fighting as many as 60% of professional boxers have detectable mental changes, and that 5% have the slow dementia, rigidity, and tremor of punch drunkenness Less is known about the risk to our 100,000 amateur boxers[2–4], but obviously this is not so great

Electro-encephalographic (E E G) changes in boxers have been extensively studied Dow et al[5] found that such changes tended to disappear thirty minutes after the injury, but Busse and Silverman[6] reported persistent abnormalities in over a third of 24 professional boxers, compared with Gibbs's[7] figure of 15% for controls The degree of E E G abnormality could not be correlated with the length of the boxing career, but the more severe disturbances are found in men who have been knocked out and in the less efficient fighters Larsson and his associates[3] studied 75 amateur boxers, of whom 44 were examined both before and after their bouts and the remaining 31 only because they were suspected of having sustained head injuries An E E G record was taken within thirty minutes of the match In the first group 1 in 8 of apparently uninjured boxers had E.E G abnormalities—a proportion close to that found from records taken before the fights—but after knockdowns or knockouts the abnormality rate rose to about 1 in 2. Of the 31 boxers suspected of having sustained head injuries over half showed E E G abnormalities Control studies excluded effects on the E.E G of physical exertion, and it seems probable that, in the first group, recordings before the fights eliminated confusion due to maturation defects

As Blonstein and Clarke[2] point out, ideally every boxer should undergo E E G examination before taking up boxing By comparison of the initial record with subsequent records the clinical significance of E.E G changes might be made clearer Meanwhile the risks to amateurs of repeated minor cerebral damage cannot be accurately assessed, but it seems most unlikely that these ever lead *to the severe disorders sometimes found in professionals*

MECHANISM OF FEVER

THE body-temperature remains constant by a fine balance between heat production and heat loss Except for slight diurnal variations and the ovulatory rise in women, the temperature in health is remarkably constant. We are almost entirely ignorant of the mechanisms by which the body-temperature is increased in *disease*, the metabolic effects of pyrexia, and whether pyrexia is advantageous to the organism[8]

Some stages in the febrile response have been identified experimentally The administration of a pyrogenic substance is followed by a latent period, varying between species but constant for a given species, in animals it lasts for 15–30 minutes, and in man for 45–90 minutes During this interval there is a leucopenia,[9] owing to sequestration of leucocytes in small blood vessels.[10,11] Wood[12] has suggested that during this sequestration the leucocytes release a pyrogenic substance, which, according to Fair et al,[13] combines with a factor contained in the α or β globulin in the serum It is not known how this factor or other factors exert their effects but they may act directly on the thermoregulating centres

The suppression of pyrexia by cortisone[14] has been studied by Atkins et al,[15] who induced fever in rabbits by administering either pyromen or native dextran They found that such suppression was independent of the initial leucopenia, and the "serum factor" was unaffected They concluded that cortisone must produce its antipyretic effect by acting on some "later and as yet undefined" stage of the fever mechanism

As Atkins et al remark, artificially induced fever may involve mechanisms other than those which operate in man Long[16] has shown that whereas man, monkeys, and guineapigs react similarly to cortisone, rats, mice, and ferrets react differently In evaluating the effects of cortisone, differences between species may be of the utmost importance Finally, it could be equally well argued that cortisone was producing its antipyretic effect in rabbits by interfering with the liberation from leucocytes of the postulated initial pyretic substance

RESEARCH AND THE PATIENT*

L J WITTS
M D Manc., D.M Oxfd F.R C.P
UFFIELD PROFESSOR OF CLINICAL MEDICINE UNIVERSITY OF OXFORD

THE finance for this new unit has come from the free onies, which are the National Health Service's heritance from the endowments of the old voluntary stem endowments whose size reflected not only the ealth of the surrounding community but also its sense f responsibility for the prevention and treatment of isease. The need for local initiative is greater than ever nder the National Health Service where the risk is that nthusiasm may be stifled and everything reduced to one ead level. We remember how in the time of Spain's reatness, Philip II imposed a highly centralised dministration on her and the ardent spirit which had red her local democracies at home and her conquista ores overseas was quenched and died. We remember oo Albert Schweitzer's warning

> "If a comprehensive organisation is established in any epartment of social life the results are at first magnificent ut after a time they fall off. It is the already existing esources which are realised at the start but later on the structive influence of such organisation on what is living nd original is clearly seen in its natural results, and the ore consistently the organisation is enlarged the more trongly its effect is felt in the repression of creative and piritual activity

Those of us who are engaged in medical education and search fear the treason of the clerks who wish to have verything tidy and circumscribed and who forget that he oak sheds ten thousand acorns to produce another ree and the fish spawns a million eggs to maintain the ace of fishes. Research requires a spirit not of prodi ality but of magnificence using that word as it was used y the Greeks who thought that three virtues are ssential if a democracy is to remain great—proper mbition magnificence and greatness of spirit. If we re to have magnificence in our National Health Service e are more likely to get it from local pride than central uthority.

We are opening a unit in which doctors and patients re going to collaborate freely and consciously in the tudy of disease. This unit has been established not by the University which has a duty to advance knowledge nd in Birmingham has signally advanced it but by the Regional Hospital Board which is responsible for the are of the sick. The board's policy and the collaboration to which it will give rise seem to me both enlightened nd significant. As the surgeon in *The Doctor's Dilemma* aid

> "It's always the patient who has to take the chance when n experiment is necessary. And we can find out nothing ithout experiment"

Cooperation between doctor and patient in advancing ur knowledge of medicine has occurred ever since the Hippocratic school of Greek physicians started to study isease objectively. We depend on the patient for the escription of the symptoms and for much of the natural istory of disease. As in other fields of science however, he descriptive method soon exhausts itself and the alue of modern accounts of disease by patients who have uffered from them is literary and inspirational rather than cientific. Hippocratic medicine was scientific in that t endeavoured to predict the course of illness as the astronomer predicts the appearance of a comet and the chemist predicts the effect of dropping a piece of metallic sodium into a bowl of water. But the endeavour of science is to proceed from prediction to control of the future and the collection of data and the construction of hypotheses must be followed by experiments. In medicine this first takes the form of attempting to alter the course of disease by treatment and once we begin to treat patients we are embarked on the troubled sea of human experiment.

Near here at Edgbaston Hall there formerly lived the physician, William Withering who established the treatment of heart-disease with digitalis the active principle of the foxglove, and who was one of the pioneers of clinical research. This was before the establishment of a hospital in Birmingham and Dr Withering used to see poor people at his rooms without a fee, for one or two hours a day. In this way he saw from 2000 to 3000 patients a year and it was mainly from them that he collected the 163 case records which formed the substance of his monograph on digitalis. From his observations on these patients he was able to show that the foxglove was the active agent in the bunch of simples which the old woman of Shropshire had successfully used in patients with heart-disease and he went on to work out in detail the best method of preparing and administering the drug.

In Withering's work the immediate relief of the individual patient was at all times the primary objective of the physician. It is well known however that the advance in morals which, despite setbacks, we consider to be exemplified by the progress of the human race has been characterised by the postponement of immediate satisfactions for ultimate gains which will be larger and as a rule more widely distributed through society. The question now arises how far this concept is applicable to the practice of medicine if it is granted that the aim of medical science is not merely to predict but to control the future. Are there not occasions when the detailed study of the effects of disease and the deliberate reproduction of symptoms may bring rewards far greater than the immediate resort to traditional remedies?

What I have in mind is exemplified by Beaumont's studies on the young French Canadian Alexis St Martin. Alexis had sustained a gunshot wound which left him with a hole in his side through which could be seen the inside of the stomach and the workings of the digestion. Beaumont who had saved Alexis's life after this dreadful accident went on to study the digestive process through this window on her secrets which Nature had so fortuitously provided. Alexis proved a somewhat reluctant subject and Beaumont had to pay him for his pains, indeed he engaged him as his servant. Beaumont's *Experiments and Observations on the Gastric Juice and the Physiology of Digestion* published in 1833 was the foundation of modern knowledge of gastro-enterology.

Or we may think of C H Blackley of Manchester who published an account of his experimental researches on hay fever in 1873. Himself a life long sufferer from hay fever he was the first to show that hay fever is due to pollen. He produced hay fever in himself and other predisposed people by sniffing the dust of blossoms and the pollen of grass and he showed that the application of pollen to a scratch in the skin resulted within a few minutes in severe itching swelling and sometimes even hay fever. The control of malaria as of other tropical fevers has also depended on experiments with volunteers culminating in the brilliant work of Hamilton Fairley and his colleagues in the last war. Millions of lives have been saved and vast tropical territories made accessible to the human race by clinical research and experiment on malaria.

The long journey which has brought mankind from the little bands of food gatherers of the Old Stone Age

---

An address given on May 18 at the opening of the metabolic research unit set up by the Birmingham Regional Hospital Board at Little Bromwich Hospital.

whose life Hobbes described as "solitary, poor, nasty, brutish and short," to the great multitudes who dwell in conurbations like the Birmingham region and have an expectation of life of seventy years or more, has only been made possible by science, and science depends on experiment The pestilences which ravaged mankind on this onward march, the Black Death, typhus, small pox, cholera, and yellow fever, are still at the frontiers of civilisation and would lay waste our cities if we relaxed our guard New diseases, physical and mental, have appeared with the strain of civilised life, the change in human nutrition, the hazards of industry and transport, and the ageing of the population The discoveries of the energy of the atom and of the infinite extent of the universe pose medical as well as religious problems The need for experiment is not likely to diminish

The thousands of patients whom William Withering treated at Edgbaston have gone their way, and of their persons and their feelings no other record remains save his monograph on the foxglove The names which are enshrined in the nomenclature of disease are for the most part those of the doctors who wrote and not the patients who suffered Here, happily, a change is occurring A number of the rarer blood groups are called after the people in whom they were first observed—Kell, Duffy, Kidd—and the newly discovered variant of hæmophilia, Christmas disease, was so called not from the date of the original publication but from the name of the first recognised case We may yet live to see the day when it is normal practice for the patient to join with the doctor in the authorship of a publication on experimental work on his illness

There is at present a good deal of uninspired clinical research, research of which we may say, in Lord Macaulay's words, "The inquiry may amuse us but the decision leaves us no wiser" Apart from ethical problems, therefore, it is a good thing that clinical science and human experiment should recently have come under sharp scrutiny There is need to bring together in frank cooperation the people who do the experiments and those who submit to them If only those things are done which can be explained and agreed to by an intelligent patient, clinical research as a whole will greatly gain Not only what is unreasonable but what is jejune and trivial will not be tolerated A voluntary hospital used to mean a hospital in which the doctors gave their services voluntarily, it may come to mean one in which the patients voluntarily coöperate in research It will be necessary to educate the public to promote understanding of the continued need for clinical research, but it is high time the British medical profession paid more attention to the necessity for educating the public in medicine It is no longer possible to preserve medicine as a mystery, even if it was desirable, for we now have a National Health Service and the State is the major supporter of medical research and of the universities Today, therefore, we celebrate not only the active interest of organisations, such as the Regional Hospital Board, in medical research, but also the realisation by members of the community that clinical research is a joint enterprise, consciously undertaken together by physician, scientist, and patient

---

BRITISH ASSOCIATION OF PHYSICAL MEDICINE

THE annual meeting of this association was held at St Thomas's Hospital, London, on April 22 and 23

The Department of Physical Medicine

In a discussion on the rôle of the department of physical medicine, Dr W S TEGNER (London) emphasised the fact that physical medicine had been and was still undergoing changes and that fluidity in the composition and organisation of departments should be maintained Space and ease of access were important and many architects still thought in terms of a rigid design incapable of adaptation As regards staff, doctors, physiotherapists, technicians, and, in many cases, nurses worked together, and there might be difficulties in integrating their various activities to secure efficiency This also raised the question of the relationship of the physiotherapy school to the physical medicine department, and Dr Tegner deplored attempts to use students as a form of cheap labour, particularly where this practice had prompted the opening of a school of physiotherapy Beds and doctors in adequate numbers were required by a physical medicine department since attendances and waiting lists continued to grow all over the country

Dr W A FELL (Cambridge) drew attention to the problems peculiar to a physical medicine department outside London and the bigger provincial centres, where over 25% of the patients might come from more than five miles away and some from as far as twenty miles Poor public transport might mean that patients had to spend a whole day away from home or work to have one treatment, and those with even minor complaints sometimes found it impossible to travel the mile or so from home to the nearest point at which public transport was available The only alternative in these cases was to use expensive hospital transport At present it was necessary to treat patients in the central department because only there could be found the requisite medical and technical staff and equipment There was thus an overwhelming case for the provision of properly constituted peripheral clinics Dr Fell emphasised the particular problems of rehabilitation and resettlement in country districts where the only standard of fitness for work was complete fitness He called for a pooling of brains to solve these problems and an effort to educate doctors in what can and cannot be achieved by physical medicine both in diagnosis and treatment

Dr A. T RICHARDSON (London) said that the maintenance of closed physical-medicine departments was indefensible for any reason, since it wasted the time of patients, doctors throughout the hospital, and physiotherapists, and prevented the general practitioner from having direct access to the physical medicine specialist which was against one of the most important principles of the National Health Service It might be argued that the closed system permitted a filtering of patients referred to physical medicine specialists, but surely they were the very people best fitted to reject cases for which there were no indications for treatment in the department A great deal of time could be saved by a sound system of decentralisation whereby a patient could go to the department with a written prescription—e g, from the dermatologist for ultraviolet light therapy, from the chest department for breathing exercises, or from the orthopædic surgeon for postoperative exercises To achieve real efficiency, however, the physical-medicine specialist and the physiotherapy services must be used intelligently, and this in turn depended on the better training of students in this field of medicine Dr Richardson felt that practitioners in other branches of medicine must have a clear idea of the scope of physical medicine, and he restated, as the best working definition of physical medicine, the triad the diagnosis and treatment of the medical disorders of the locomotor system, the treatment of these and other disorders by physiotherapy, and medical rehabilitation It was now considered that the M R C P or its equivalent was essential for the attainment of consultant status in physical medicine in addition to considerable experience in the specialty, which should carry with it possession of the D PHYS MED There was now a sufficient number of fully qualified registrars to ensure that future consultant appointments would fulfil these criteria

Dr F S COOKSEY (London) expressed his concern at e shortage of physiotherapists, a shortage reflected in her fields such as nursing and school teaching Unless lowering of the standards of training for physiotherapists was to be accepted (a suggestion firmly jected by many later speakers) there would have to be continual economy in the prescription of treatment r Cooksey made a plea for a firm integration of the edicine practised in the physical medicine department ith other hospital services and with the local-authority rvices and general practitioners

Dr C J S O MALLEY (Watford) stressed the impor nce of the remedial gymnast in the rehabilitation team doctor physiotherapist occupational therapist and ualified social worker Dr B W WINDLE (Brighton) ated that mobile centres did not go far to meet the need the peripheral centres in the provinces envisaged by r Fell for the number of patients that could be treated as so small He and other speakers mentioned the pparent ignorance of many members of the profession nd lay committees of the proper function of the qualified hysical medicine specialist and his department Dr RANCIS BACH (London) suggested that joint consulta on clinics with the neurologist orthopædic surgeon and natrician went a long way to solve some of the prob ms involved in the efficient decentralisation of open hysical medicine departments

Hydrocortisone by Local Injection

Dr J H CYRIAX (London) drew attention to the great portance of accurate anatomical localisation of soft sue lesions for the effective use of hydrocortisone and discussed the diagnostic principles concerned

Dr P HUME KENDALL (London) discussing the results btained at Guy's Hospital said that in selected cases of heumatoid arthritis it had been confirmed that the ormone s chief value appeared to be the production of emission sufficient to permit more active physiotherapy han would previously have been possible In osteo rthritis hydrocortisone had been of use only in the early ase or where symptoms had been aggravated by recent njury In acute rotator cuff lesions of the shoulder esults had been good but the effect on the frozen houlder' was usually disappointing Various soft ssue lesions such as tennis and golfer s elbow plantar sciitis, De Quervain s syndrome and tenosynovitis had esponded well In acute traumatic articular effusions ncomplicated by serious bone or ligamentous injury he results were often dramatic even in the presence of hæmarthrosis, where hyaluronidase was combined with ydrocortisone after aspiration

Other speakers described the economic importance of ydrocortisone in terms of time saved by patients and hysiotherapists alike but they suggested that the neces ary associated methods of rehabilitation should not be rgotten

The programme included three short films. Dr Bach intro uced one called *Grip on the Nation* which had been made for he British Rheumatism Association for exhibition to the ublic and was concerned with the prevention and treat ent of rheumatism. Treatment at hospital spa and eripheral clinics, as well as at home was briefly yet clearly utlined

The second film *Neuromuscular Transmission in Myasthenia ravis* was introduced by Dr Richardson and had been made colour for presentation at the American Congress on yasthenia An animated cartoon was used to demonstrate hat happened at the neuromuscular junction during different pes of block

Infantile Cerebral Palsy introduced by Dr W F DUNHAM ondon) consisted of parts of three separate films, the result work done by Dr Dunham in conjunction with Mrs. Elaine ollis, and it demonstrated normal and abnormal reflexes in ildren

GENERAL MEDICAL COUNCIL

IN a presidential address at the opening of the council s 190th *session on May 24 Sir David Campbell referred* to the use in the *British Pharmacopœia* of the apothecaries system of measurement The Pharmacopœia Commission had recommended that a definite decision should now be taken to discontinue the use of the apothecaries system in the *British Pharmacopœia* of 1963

Nearly two and a half years had passed since it had become compulsory for every newly qualified man and woman to serve for twelve months as a house-officer before full registration Similar requirements had already been in existence in South Africa and most of the provinces of Canada while in New Zealand the introduction of such arrangements was synchronised with our own Since that time provision had also been made in Hong Kong Singapore and Malaya for the introduction of corre sponding requirements with effect from Jan 1 *1953* A start had now been made in introducing similar arrangements in Australia In New South Wales the requirements had been brought into effect as from November 1954 This would of course mean that practitioners from this country who wished to practise in New South Wales would be asked to produce evidence of their experience before they could be registered there The New South Wales authorities would not require such evidence of practitioners who were fully registered here before Nov 10 1954.

The means provided by the Medical Acts to enable the Register to be kept correct were simple but somewhat drastic The Acts authorised the registrars to write to any registered medical practitioner at his registered address to inquire whether he had ceased to practise or had changed his residence If no answer was returned to this letter within six months, it became lawful to erase the name of the practitioner from the Register Since 1951 letters had been sent to approximately 50 000 practitioners 2059 were untraced and their names were eventually erased In the past four years 309 names erased in this way had been restored to the Register The President invited each member of the profession to ensure that the registered address was correct and afforded a trustworthy means of communication with him

During the session the council would be discussing the medical curriculum Possibly the council s recom mendations had acquired the force of regulations and had thus come to have a restrictive effect on the diversity freedom and responsibilities of universities and medical schools The President hoped that the council would consider appointing a curriculum committee to consider the whole matter

CENTRAL HEALTH SERVICES COUNCIL

THE Minister of Health has appointed or reappointed the following doctors to the council and standing advisory committees for the period ending March 31 1958

Central Health Services Council

* Sir Stanford Cade Sir Henry Cohen Prof A J Lewis W P H Sheldon * S Wand

Standing Advisory Committees

Medical—* Sir Stanford Cade Sir Henry Cohen Prof A J Lewis H M C Macaulay W P H Sheldon * Stanley Thomas, S Wand

Dental—Prof M A Rushton Prof. F C Wilkinson

Pharmaceutical—P J Gibbons.

Ophthalmic—Macdonald Critchley O G Morgan

Maternity and Midwifery—* Prof W C W Nixon

Mental Health—N H M Burke * T M Cuthbert Prof A. J Lewis, * C A H Watts (until March 31 1956) Denis Williams; one vacancy

Tuberculosis—P M D Arcy Hart Peter Kerley one vacancy

Cancer and Radiotherapy—Sir Stanford Cade Sir Ernest Rock Carling Sir Henry Cohen Sir Charles Dodds F.R.S. Prof J S Mitchell F.R.S., V E Negus Sir Clement Price Thomas (until March 31 1957)

Public Health

AN OUTBREAK OF LEAD POISONING IN THE CANKLOW DISTRICT OF ROTHERHAM

J A Gillet
M B Lpool D P.H
MEDICAL OFFICER OF HEALTH FOR ROTHERHAM

Late on Monday afternoon, Dec 20, 1954, I had a telephone call from the Children's Hospital, Sheffield, saying that twin boys Keith (case 1) and Kenneth (case 2) B - y, aged 3½ years, had been admitted earlier that day and that a diagnosis of lead encephalopathy had been confirmed It was also stated that a younger brother James (death B), aged 2 years, had died on Dec 15 in the Doncaster Gate Hospital, Rotherham, having had symptoms like those from which the twins were suffering After a post-mortem examination his death had been attributed to status epilepticus due to idiopathic epilepsy

The general practitioner, who had diagnosed lead encephalopathy, informed me that case 2 had been admitted to Moorgate General Hospital, Rotherham, on Dec 12, but had been discharged home on Dec 14, at the parents' request, and had later been admitted to Sheffield Children's Hospital with his twin brother (case 1)

ACTION TAKEN

Next morning I visited the home of the children, together with the Chief Sanitary Inspector and the Area Health Visitor, but, as the mother was out, we visited the home of the grandmother, from which the twins were admitted, and where they had spent a good deal of their time

The grandmother was edentulous, anæmic, and constipated and complained of a metallic taste in her mouth (subsequent investigation showed no stippled cells or signs of lead poisoning) An adult son and a younger married daughter and her baby were also examined The daughter and her baby appeared healthy, but the son had a suspicious-looking blue line on his gums (subsequent investigation in his case also proved negative)

A thorough investigation of the house yielded no evidence of the source of lead, there was no fresh or damaged paintwork, there were no lead toys, and a recent routine analysis of the water-supply showed that it was free from lead Inquiry, however, elicited the fact that for some time car battery casings had been used as fuel for the domestic fire and a sample was taken from the ashes in the hearth and a piece of battery casing from the coal-house These battery casings seemed to be the only source of lead which could have caused the poisoning

The Area Health Visitor provided the information that it was a fairly common practice in that district of the town to burn battery casings as domestic fuel, and it was decided that immediate action must be taken to warn people of the danger of this practice Arrangements were made for the police loudspeaker van to tour the area and broadcast the following message

> Do not burn any more car batteries—they are dangerous and can poison you

All local newspapers were contacted and a short statement was given setting out the facts

The Chief Sanitary Inspector organised a house-to-house visit of the affected area by the sanitary inspectors, and the collection of names, ages, and addresses of all people living in houses where they admitted to burning the cases The main source of supply—a scrap metal dealer—was traced and the supply was stopped

Meanwhile, the Pædiatrician attached to the two Rotherham hospitals had been contacted, and from him it was learned that about a month before, on Nov 21, Leonard B h (death A), aged 5 years, had died, the cause of death, following a post mortem examination, being given as cholæmia and infective hepatitis This child's history was interesting in that he was closely related to the twins and their brother (cases 1 and 2 and death B) It seemed likely that he had in fact died from lead poisoning

At the same time the Rotherham Pædiatrician informed me that Leonard's two brothers Roy (case 4), aged 20 months, and Alan (case 5), aged 7 years, had attended the outpatient department, and I was asked to get them up to hospital urgently for investigation because, in the light of events, it was felt that their symptoms were suspicious This investigation confirmed a diagnosis of lead poisoning, and they were admitted to Moorgate General Hospital the same day (Tuesday, Dec 21) being transferred two days later to the Sheffield Children's Hospital. Later that day I was informed that a further child, Franc B w (case 3), aged 20 months, had been admitted from the same district in Rotherham to the Sheffield Children's Hospital with suspicious symptoms

On Dec 23, Ruth B - y (case 6), aged 5 years, who was sister to cases 1 and 2 and death B, was admitted to Sheffield Children's Hospital, and on Dec 24 two further cases, Kenneth P (case 7), aged 7 (a mental defective), and Kenneth S (case 8), aged 20 months, were admitted from the same district of Rotherham as the other [illegible] cases

By the evening of Tuesday, Dec 21, as children appeared to be at greater risk than adults because of the danger of encephalopathy, it was felt that efforts must be concentrated primarily on them Arrangements were therefore made with the Pathologist at Moorgate General Hospital that a shuttle service of ambulances and cars would be run between the homes and the laboratory on Thursday, Dec 23, so that all known child contacts could have a blood film and blood-count, and any doubtful cases could be referred to the Pædiatrician

By the evening of Dec 21 the survey by the sanitary inspectors had produced the information that 70 children and between 40 and 50 adults from 22 houses had been involved. As it was suspected that householders were not admitting to exposure, the press were asked to publish a warning about the seriousness of lead absorption with delayed symptoms in children This produced an increase in numbers so that by Wednesday night, Dec 22, 127 children and 123 adults from 40 houses were found to have been at risk

During Wednesday households were visited and all battery casings surrendered—together with ash, which it was felt constituted an important hazard—were transported and disposed of by a Health Department van Over three tons was collected in this way

During Wednesday, householders were informed of the arrangements for examining the children the next day and also that Health Department medical officers, accompanied by health visitors, would visit each suspected home that evening and examine the adults for clinical signs, which would decide whether a blood examination was necessary for them The medical officers were given lists of names and addresses and asked to complete the following form for each case seen

Suspected Lead Poisoning

Full name ——————————— Age —
Address ———————————————
Name of family doctor ———————————
For about how long have batteries been burned in the house? ———————————
Condition of gums and teeth (if any) ? blue line
? Anæmia ———————————
Any other symptoms (e g, anorexia constipation habits wrist drop foot drop) ———————
? Blood test required ———————————
Any other comments ———————————
Signature of Medical Officer ——————— Date —

On Wednesday the following circular was sent out by hand to all general practitioners in the area

"As you may be aware cases of lead poisoning have occurred in the Canklow district of Rotherham The cause has apparently been the burning on domestic fires of old motor car batteries. So far approximately 60 children in the area are thought to have been at risk and arrangements are being made for these to have a blood test (to examine for stippling) at Moorgate General Hospital Laboratory X ray examinations of bones may be required later depending upon the result of the blood test These procedures are necessary on account of the potential seriousness of the condition in children and the possibility of lead encephalopathy Should you become aware of any cases in your practice I should be glad to be informed. In adults the condition may not be so serious but arrangements are in hand for homes in which the batteries have been burned to be visited by members of my staff Adults showing a blue line anæmia or other suspicious symptoms will be referred for blood examination. Should I become aware of an established case of lead poisoning in your practice I will notify you as soon as possible

The Physician Superintendent of the Moorgate General Hospital was contacted on Wednesday Dec 22 with a view to making arrangements for the medical examination of suspected cases among the adults and he agreed to hold a special outpatient session if necessary for this purpose At the same time he agreed to admit to hospital immediately any cases of lead poisoning that the general practitioners felt should be admitted

During the evening of Dec 22 127 adults and children were examined in their homes by medical officers of the Health Department accompanied by health visitors and all children and all doubtful adults were referred to the Pathological Laboratory at the hospital for blood test.

During the morning and afternoon of Thursday, Dec 23 a shuttle service of ambulances and cars conveyed children and a few adults, to the laboratory escorted by health visitors Subsequently parents and children attended the laboratory unaccompanied either because of advice given by the health visitors sanitary inspectors or their own doctors, or because they had heard that their blood could be examined and they wished to be reassured that they were in no danger after being exposed to risk

The health visitors later assisted in the persuasion of defaulting members of families to attend for tests The Sanitary Inspectors continued their house to house visits and by Dec 31 had paid 1039 visits to houses

As more cases came to light a number were found to be affected by jaundice and investigations were made into the possibility of this being caused by some toxic substance present in the battery casings Antimony seemed to be the only substance of this type which was present and it was felt that the amount present was not sufficient to produce jaundice

I am satisfied that the jaundice was in fact infective jaundice partly because there were several minor epidemics in the Canklow district of Rotherham and in areas around Rotherham and partly because a sister who attended one of the first cases of encephalopathy to develop jaundice became jaundiced herself four weeks later In some cases the jaundice was responsible for producing symptoms of acute lead poisoning in children already suffering from lead absorption or chronic poisoning

By Dec 31 287 blood specimens had been taken and 240 of these had been analysed and by Jan 7 330 had been taken and examined A further 14 bloods were taken and analysed during the following week making a total of 344

Of these 122 were from adults and 222 from children and infants These were apart from the 8 children who had been admitted to Sheffield Children's Hospital 3 of whom were transferred there from Moorgate Hospital Rotherham, in order that they might have the advantage of treatment by calcium disodium versenate which was available there

Of the 122 adults 55 with suspicious signs such as anæmia were referred for clinical examination by the Physician-Superintendent of Moorgate General Hospital Only 27 of these could be persuaded to attend in spite of repeated requests and in spite of arrangements being made to hold clinics at special times convenient to them

Of the 222 children and infants 112 were referred to the Rotherham Pædiatrician for further investigation

No cases of lead poisoning have been diagnosed in adults

124 reports have been received so far on the infants and children This includes a number of children who were already attending the hospital but were called up for special review in the light of events

	Lead poisoning	Lead absorption	Negative
Inpatients	5	13	4
Outpatients	0	36	66
Total	5	49	70

All inpatients have been discharged from both hospitals The last to be discharged were cases 1 and 2 who were discharged on Feb 23 to the care of their own doctor

On Saturday Jan 8 James B y (death B), aged 2 years and Leonard B h (death A) aged 5 years were exhumed on the instructions of the Rotherham Coroner and a post mortem was performed Analysis of the organs indicated that these two children had died from inhalation of lead and at the adjourned inquest on Feb 10 the jury found accordingly, adding a recommendation that steps should be taken to prevent the burning of car battery casings

FOLLOW UP

Arrangements have been made for those cases where it is recommended by the pædiatricians and where it is felt that the parents cannot afford this that a pint of free milk is supplied daily Payment for this will be made from a voluntary fund which is at my disposal In the first instance the supply is given for a month and will be extended if necessary to meet clinical requirements The pædiatricians will continue to follow up the cases clinically but in view of the possibility of mental retardation following lead poisoning in children which has been reported by some authors it is proposed that certifying school medical officers shall conduct intelligence tests on all children diagnosed as having suffered from plumbism All tests which are made will be repeated in approximately six months time and again after a year Four of the children have already been tested in this way and the intelligence quotients (Terman and Merrill form L) are 81 73 83 and 91 The two original cases have been seen by a psychologist attached to Sheffield University Education Department and he gives the intelligence quotient (Terman and Merrill) as 72 for Keith and 63 for Kenneth

THE BATTERY CASINGS

The battery casings vary slightly in composition as between the products of one firm and another, but in the main they are made of vulcanite which is composed of a mixture of bitumen asbestos and ebonite

The essential unit of the battery is the plate containing a conductive framework or grid which holds the active lead material It is made of lead 88-93% antimony 7-12% and tin 0 3 0 4% with small quantities of arsenic and copper (0 05% in total)

The grids for the positive and negative plates are of similar construction The paste most commonly used as a filler for the grids consists of litharge (PbO) or red lead (Pb_3O_4)

or a mixture of the two The mixture is made into a stiff paste with sulphuric acid when a reaction occurs which leads to the binding together of the material on account of the formation of lead sulphate and peroxide (PbO_2) These plates after drying are alternately oxidised and reduced by electrolysis in dilute sulphuric acid The final result is that the paste of the negative plates becomes reduced to metallic lead and that of the positive oxidised to lead peroxide

Accumulators in repose contain, besides small quantities of litharge and red lead, three active substances—spongy lead on the negative plates, spongy lead peroxide on the positive plates, and dilute sulphuric acid between them. Sulphate of lead is formed on both plates during discharge and brought back to lead or lead peroxide during charge The separators between the plates are made of porous wood, or more recently of porous rubber or plastic

During use, and especially when the life of the battery is nearing its end, small particles of the various constituents of the plates including some metallic lead, lead peroxide, and lead sulphate become detached and fall to the bottom of the casing where special recesses are constructed below the plates to receive these particles so that they shall not interfere with the conductivity of the battery In time a slimy grey brown deposit of these constituents is formed which consists largely of lead sulphate

The old batteries are purchased from various sources such as Government sales, and from firms who run a part-exchange system replacing the old battery by a new one and making a small cash adjustment They are brought to the scrap yard and dumped ready for breaking up In the particular scrap-yard involved, in the present investigation a sledge hammer is used to crack the casing, the sulphuric acid is allowed to run out, and the lead plates are salvaged while the broken casing is treated as waste, being placed on a dump where members of the public came to buy or otherwise acquire them, taking them home in sacks, in wheelbarrows, or in some cases in the family perambulator There they were stored in the coalhouse or in the open until they were burnt on the fire

Many of them had been put to a variety of uses In some cases the children were allowed to use them as bricks for play, in others they had been used as ladles for conveying pig food to the trough, and they had also been burnt on bonfires both in the open and in one case in an air raid shelter

RESULTS OF BURNING

The casings burn well but with a very smoky flame and an obnoxious smell, and small hot fragments tend to become detached and to be projected from the fire into the room Several children seen had sustained small burns on exposed arms and legs from this cause

An attempt was made by the Chief Sanitary Inspector to reconstruct the circumstances in an empty council house of a similar type to the houses on the estate involved A fire was lit and car batteries were burnt throughout the day and the following analyses were made by the Sheffield Public Analyst

(1) Deposit removed from portion of battery case expressed as lead sulphate	82 %
(2) Dust and fragments from breaking up of battery cases expressed as lead sulphate	10 46 %
(3) Cinders from burning of battery cases expressed as lead sulphate	1 5 %
(4) Flue dust	12 50 %
(5) Hand washing water	0 024 %

A sample of flue gas and air in the room used for the experiment failed to reveal the presence of lead

A further test using a closed stove has been made and in samples of flue gas taken no lead fume could be detected

The temperature of the stove fire was recorded during this experiment varying between 700°C and 1000°C An unofficial report has been received from an industrial firm (not in Rotherham) who have for some years made a practice of burn battery casings on a furnace This indicates that repeated tests of flue gases have failed to reveal lead fum and that the tendency is for any lead present to melt and to fall through the bars of the furnace

These results show that considerable quantities of lead and lead salts were involved, and that very little if any of the lead salts or of lead fume escaped by the chimney In fact the temperature of an ordinary domestic fire would not be sufficiently high to produce "fuming" of the lead

The chemical changes produced by burning would depend on the temperatures reached Margaret Fishenden in her book *House Heating* quotes Darling as giving the average temperature of a brightly burning coal fire at about 1407°F (764°C) She also states that the radiating surface temperature will generally be above 1000°F (538°C) and below 2000°F (1093°C) and later on gives limits of 750°F (398°C) to 1750°F (954°C) with a mean of 1500°F (827°C) For purposes of convenience it can safely be assumed that the temperature of a domestic coal fire does not exceed 1000°C

The following pertinent figures are given in *Lange Handbook of Chemistry* (1946)

Lead

Melting point	327°C
Boiling point	1620°C

Vapour pressure in mm mercury	
808°C	0 08 mm
996°C	1 75 mm
1178°C	10 80 mm
1620°C	760 00 mm.

Other lead compounds

	Melting point
Lead sulphate	1170°C
Litharge (PbO)	888°C
Lead peroxide (PbO_2)	290°C (with decomposition)
Red lead (Pb_3O_4)	500°C (with decomposition)

Assuming a temperature of 1000°C as being that of a domestic fire, the chemical changes taking place are

(1) Red lead and lead peroxide break down to produce litharge

(2) Litharge is reduced to produce metallic lead

(3) Lead sulphate is unchanged.

(4) Metallic lead produces very little fume at that temperature and the small quantity which was produced would be carried up the chimney by draught The distance it would travel would be very short as it would rapidly cool and it would be precipitated in the flue or fall back into a fire grate

These facts rule out the possibility of poisoning, by inhalation of lead fume and explain the results of chemical analysis obtained and in particular

(1) The failure to detect lead in the flue gases

(2) The presence of lead in the flue dust

THE ASH

Two possible sources of lead are left

(1) In the fresh casings

(2) In the ash

There are also two possible portals of entry

(1) By ingestion—due to contamination of fingers and foo or in the case of smaller children by sucking pieces of batter casing

(2) By inhalation of ash

The post mortem findings in the two children who di showed

Death A	Lungs 0 24 mg	lead per 100 g tissue
	Liver 1 12 mg	" "
	Kidneys 1 39 mg	" "
Death B	Lungs 0 29 mg	" "
	Liver 1 28 mg	" "
	Kidneys 1 56 mg	" "

The fact that in death A the liver contained almost f times as much lead as the lungs and less than the kidn and in death B the liver contained almost four times much lead as the lungs and less than the kidneys stated to indicate that the poisoning was due to tion as a case of lead poisoning by mouth was quoted where the liver lead was thirty times the lung lead and more than the kidney lead But this conclusion, which was based on the findings in one case only did not take into account that both children were jaundiced for some time before death—death A severely and death B slightly This would tend to interfere with the absorption of lead taken by mouth

Although the route of entry of lead into the system must remain a matter of conjecture it is interesting to study the ages of the affected patients In 293 adults (i.e., over the age of 15 years) at risk only 1 case of lead absorption was detected and this was in a girl of 15 In the 232 children under the age of 15 at risk it is a striking fact that of a total of 55 cases of lead absorption or lead poisoning 51 were under the age of 7—i e of an age where they are likely to put things in their mouths The youngest child affected was 10 weeks old lived in a household where the standard of hygiene was not good, and is the proud owner of a dummy which is not an unlikely vehicle for conveying lead contaminated ash from the floor to his mouth

PROTECTION OF THE PUBLIC

In the outbreak under investigation the wide publicity which was given locally to the dangers associated with the burning of battery cases and the weight of local public opinion were sufficient to cause the cessation of this practice and to prevent the scrap dealer concerned from allowing the public to have access to the casings But it is a striking fact that the dealer informed me that some two weeks after the initial cases had been discovered, and while the publicity given to them and to others was at its height he was approached by several people who asked for casings to be used as fuel. He refused to supply them.

It is another striking fact that in one family where at least three of the children were known to be affected though without any gross symptoms, and where the mother herself showed some signs suggestive of lead absorption, the parents complained that a source of cheap fuel had been closed to them stating that they were prepared to continue the practice of using them as fuel and were only discouraged by the opinions of their neighbours and by the fact that no casings were available

So far as I can ascertain there is no law to prevent the scrap-dealers from disposing of this waste material as they wish, or from dumping it in such a place that the public have free access to it It is extremely doubtful whether any action could be taken by an aggrieved person against the supplier of the battery cases, even though he might be aware of the potential danger attached to them Nor do there appear to be any powers to prevent people from using the material as domestic fuel unless one could make use of section 92 of the Public Health Act 1936 which is very dubious.

Failing this it might conceivably be possible if there were children in the home to make use of section 1 of the Children and Young Persons Act, 1933 on the grounds of neglect—though the successful outcome of a prosecution under this section of the Act would also be very doubtful and in any case could only be considered after the damage to the child had already occurred and the practice was continuing

It appears that provision should be made for the registration and inspection of premises used for this purpose as well as for the safe disposal of waste

Undoubtedly the safest method of disposal would be controlled tipping and burying of the material If incineration in a destructor is to be the method of disposal cleansing of the battery casings by hosing should precede burning in the destructor to remove as much of the adherent lead salts as possible This procedure would no doubt leave a certain amount of lead salts in the cracks in the casings; but, even though the forced draught of the destructor might convey some of the dried lead salts up the chimney it is doubtful whether, providing the casings were diluted with other waste materials during burning there would be any appreciable pollution of the atmosphere

Poliomyelitis Vaccination

The number of children in the United States who have had poliomyelitis shortly after vaccination stood at 79 on May 21 [1] There have also been about 30 reported cases among people in close contact with vaccinated children who did not themselves have any illness.[2] The significance of this new development is hard to judge without more details of the present incidence of all forms of poliomyelitis in the United States, but the total of contact cases seems too large to be explained by natural infections and it is difficult to avoid the conclusion that the vaccination was in some way involved And, as we observed earlier,[3] the most likely cause is incomplete inactivation of virus in certain batches of vaccine

The future course of the vaccination programme in the United States was to be discussed at a meeting in Washington on May 23 It has been suggested that the decision may be to postpone further vaccinations until the autumn At present the clearance of vaccine has been stopped to await the results of a re-examination of manufacturing methods and safety tests. But children are still being vaccinated with previously cleared vaccine, and in New York on May 20 22 827 school-children had their first injection [4] This figure was 69% of the expected number judging from the total of parents who had originally agreed to vaccination. On the day before when New York's programme began 71 5% of the expected number had been vaccinated

The poliomyelitis advisory committee of the United States Public Health Service have been considering among other things the possibility of using smaller doses of vaccine given subcutaneously and they set out their recommendations in a statement published on May 20 [4] They believe that it would be unwise to recommend procedures which are less effective antigenically, and they recommend sticking to the three intramuscular injections of 1 ml. The second dose should be given two to six weeks after the first, and if possible before the poliomyelitis season begins although the second dose is beneficial even if given after a number of months" The third dose should be given about seven months after the first. This, the committee say, produces the best antibody response They add that, in their view, the administration of vaccine during an outbreak of poliomyelitis has its place in preventive medicine The second dose can be given during an outbreak without appreciable concern for the phenomenon of provocation since slight immunity resulting from the first dose of vaccine will most likely provide protection against any such effect.

Marriage Statistics

The Registrar General has lately published part II (the civil tables volume) of his review for 1953 [5] Among the less familiar indexes of human welfare is the marriage-rate which in 1953 was 15·6 persons married per 1000 population in England and Wales There were more marriages in the London and South Eastern Region than elsewhere—the rate being 16 7 The most popular months for marriage were March and August and the least popular November The most common age for marriage remained 2? for men and 21 for women and there was more intermarriage between men of 23 and women of 21 than between men and women of any other combination of ages

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN you take your child to the follow-up clinic the doctor says, "Well, Mrs X, and how is little Johnny's nose (or throat, or chest) now?" And you say, "Much better, doctor He's a different child since his operation" Whereupon Doctor, Sister, and you all beam at one another and at little Johnny, and a hieroglyphic on little Johnny's case sheet adds to the statistically significant successes in nose (or throat, or chest) operations

But supposing some of the Mrs Xs said some of the things left unsaid? It is perfectly true that the little Johnnies are different children since they left hospital, but if their mothers described in detail some of the differences the interview would be something like this

Mrs X "Well, Doctor, his nose (or throat, or chest) is certainly better, but he's *a different child since his operation* He's so fussy over his food now—won't eat anything with a spoon any more, just biscuits and bananas, and he used to be so good over his dinners He won't use the pot any more, Doctor, he always does it on the hearthrug now He won't go out to play alone It's 'Mummy, Mummy, where are you?' all day long And he's dreadful at night—scenes over going to bed, and he wakes up screaming with dreadful dreams about blue ladies"

This is all rather near the bone for us, as our under-3 has just spent twelve days in hospital (Excuse me while I go and sponge the hearthrug) He takes a very long time over his meals now, though he used to be the world's fastest eater, but he does get it all down eventually, and he's already back to his preoperation weight He's developed a siren scream when thwarted, so high-pitched that if only it was a little higher I should be spared from hearing it At bed-time he calls out again and again, and begs me to sit on his bed and hold his hand He keeps asking for drinks—anything, in fact, to postpone going to sleep It's usually his brother (over-5) who calms him down I hear him shouting in great irritation, "*Do* shut up! I can't hear myself sing"

Over-5 feels that too much fuss has been made of under-3, and though we try to avoid mentioning hospitals, injections, and so forth, over-5 has no such fine feelings. He opened the door to our kind and charming surgeon and at once said, "Here's Mr B come to take you back to hospital!" When I remonstrated with him (after the ensuing hubbub had died down) over-5 said, with elder-brotherly candour, "Well, I hoped he was!"

* * *

The visitor to the Principality may think that such appellations as Thomas-the-Fish, Harries-the-Hearse, or Dai-small-coal are applied frivolously But the natives are in earnest when they attempt to compensate for their ancestors' lack of imagination in the matter of surnames The flexibility and scope of the system were shown by my Welsh patient lately

After responding rapidly to my treatment of his pneumonia, he was unfortunate enough to prolapse his lowest gut, and I paid him social visits in the surgical wards Later, while I was away, he came again to the hospital, this time as a visitor to his small son, recovering from a tonsillectomy Wishing to be remembered to me, but realising that even in London his surname was about as common as the cases of fog pneumonia, he pondered some way of identifying himself Wales came to his aid "*Please tell Dr D,*" he said to the house-surgeon, "that very best wishes are sent by Evans-the-Rectum"

* * *

Driving has always been a bone of contention in our family, and I have never been allowed to forget that I failed my first driving test at the age of 17, whereas my wife passed hers, first attempt, at the same age So it was with considerable trepidation that I approached my test in the States "Well, brother," said the examiner, as he moved his gum from one corner of his mouth to the other, and brushed aside my British licence, "what is a soft shoulder?" Resisting an impulse to be facetious, I told him, for I had studied the book as intensively as if I were preparing for the membership When he had visual fields and colour vision and we had spent some ten minutes discussing the technicalities of right-of way at intersections and school bus laws, we sauntered out to the roadway Just then a little A 30 went bowling past along the road "Gee," said the examiner, "just look at that cute little English car O K in your country I guess, but not over here, no protection!" As I digested the significance of his remarks and let in the clutch, I heard him say "They tell me they drive on the left in your country" I murmured assent "Is that so," he drawled, shaking his head over this curious idea My memory of the succeeding half-hour is dim, but I know that in the heavy traffic and unfamiliar surroundings, it was a harrowing experience as we performed every conceivable manœuvre. As I clutched my newly won licence, my account at home that evening, though lurid, was given with an air of conscious superiority When my wife's turn came a few days later, she was trembling visibly As she went to face the inquisition I settled down in the car prepared for a long wait. But only a few seconds had elapsed when she and the examiner returned to the car; in a few moments more she had driven 50 yards down the road and back and her test was over We drove home in silence The demands for equal pay for women leave me cold, coming from a sex which enjoys so many other advantages

* * *

It may or may not interest the Royal College of Physicians to know how high it stands in my bank manager's estimation His branch is small enough for him to take a personal interest in the details of his clients' accounts He tends to judge one's social stature by the club to which one belongs, and the standing of the club by the size of its subscription I am high on his list, for he has long regarded the college as among the more exclusive of the Pall Mall clubs, my regular half-yearly 15-guinea "subscription" has fostered and maintained this illusion But now even the Athenæum pales into insignificance since the clearing-house informed him of my latest contribution—for more than twice the usual amount.

It will be six months before he suspects what my pride forbids me to explain to him, that there will be no more "subscriptions" At last I have passed the membership.

* * *

I have been less fortunate than my peripatetic colleague who finds "Lie down on the couch, please" an adequate instruction The keen patient asks which way up, and blow me down, even then he may get it wrong When I want to examine the back as well as the front I specify the position, but accept whichever is adopted without comment, except "Now turn over" at the appropriate stage There is, however, still the rara avis who suddenly realises he is wrong and turns over with profuse apologies in mid-palpation Against him I know of no defence except patience

* * *

It was just before a previous general election, I remember, and the patient was in a tragic state of almost complete quadriplegia due to the most severe subacute combined degeneration of the cord that I have ever seen Though he had a large intractable bed-sore, he kept up his morale well, but he could not quite stand up to the political arguments of the other patients A staunch Conservative in the past, he was fast succumbing to the ward influences and beginning to wonder whether he ought to vote Labour this time

We thought we might be able to stimulate the indolent tissues of his bed-sore by daily doses of testosterone. The effects were pronounced but unforeseen The bed sore remained much as before, but his morale and strength of will improved so much that he was now able to argue back with vigour in the ward political discussions To such effect did he do this that he actually converted several of his fellow patients to the Conservative point of view Perhaps there is a future for political endocrinology in influencing the floating vote

* * *

I was so stirred by Dr Cicely Williams's hexameters in last week's *Lancet* (p 1071) that I should like to offer this tribute to her learning *utriusque linguæ*

Letters to the Editor

THE MYSTERY OF DENTAL CARIES

SIR,—With regard to your leader of May 14 I venture to suggest that the "mystery" has been overstated. It has been shown that the exciting factor in the production of dental caries is the achievement of a high sugar concentration on the tooth surface and maintenance of this condition for comparatively long periods of time. This is associated with two factors: the frequency with which the sugars are taken into the mouth and the physical nature of the sugars. Exhaustive investigations into dental caries carried out under the auspices of the Royal Medical Board of Sweden first published in 1952 reached the following conclusions:

(1) The consumption of sugar can increase caries activity.

(2) The risk of sugar increasing caries activity is great if the sugar is consumed in a form with a strong tendency to be retained about the teeth.

(3) The risk of sugar increasing caries activity is greatest if sugar of that form is consumed between meals, thus increasing the number of times a day that sugar is taken.

These findings have been endorsed by many other investigations.

In the M.R.C. investigation both control and experimental groups received sugar with meals. Their oral sugar clearance time was probably similar, and it is therefore no surprise that the dental caries was also similar in the two groups.

G. J. PARFITT

MESTINON IN MYASTHENIA GRAVIS

SIR,—'Mestinon'[1] (pyridostigmine bromide) is the dimethyl carbamate of 3 hydroxy 1 methyl pyridinium bromide, an analogue of neostigmine. It is said to be longer acting and less toxic than neostigmine.

The clinical value of this drug has been assessed in 10 cases of myasthenia gravis. During this trial one tablet (15 mg.) of neostigmine was taken to be equivalent to one tablet (60 mg.) of mestinon.

Of these 10 patients, 7 expressed a preference for the new drug because they felt its effect was greater and lasted longer than that of neostigmine; 1 found no difference; and 2 preferred neostigmine on the ground that the side-effect of abdominal discomfort was accentuated by mestinon. In this respect the other 8 patients found this symptom, if anything, less troublesome.

Allowing for the natural reaction of most of these patients to interpret any new form of therapy as being better than their present one, the best assessment of the usefulness of the drug can probably be gained from a study of the disease in its severest state. 2 of our patients were in this condition. Both required large doses of neostigmine every two hours during the day and had to be roused for further doses every three hours during the night. Despite this heavy dosage they were extremely weak on rising in the morning. After a control period of five days during which the dosage of neostigmine was constant, mestinon was substituted. The improvement was dramatic. Both patients were able to sleep unmolested from 10 P.M. until 6 A.M., at which time their general muscle strength was slightly better than during the control period.

A survey of the results of this small clinical trial of mestinon in the treatment of myasthenia gravis suggests the following:

(1) 60 mg. of mestinon produces slightly greater improvement of muscle strength than 15 mg. of neostigmine.

(2) The onset of action of mestinon is slower than that of neostigmine. This may be partly accounted for by the delayed absorption caused by the sugar coating on these new tablets, which has since been discontinued.

(3) The effect of one tablet of mestinon lasts about half as long again as that of neostigmine. This was supported by a similar finding with intravenous injection.

(4) The incidence of abdominal colic is less with mestinon.

All these findings indicate only a minor improvement on a drug which, for the last twenty years, has played a revolutionary part in the treatment of myasthenia. The greatest usefulness of mestinon would appear to lie in the increased duration of action, which is particularly beneficial in the severely ill patient. It might also offer a satisfactory alternative treatment to neostigmine, especially if the latter produces troublesome side-effects.

Our thanks are due to Roche Products Ltd. for supplies of Mestinon.

TREATMENT OF ACTINOMYCOSIS WITH HYDROXYSTILBAMIDINE

SIR,—The report by Dr. Wolff and his colleagues (May 14) on the successful use of hydroxystilbamidine in severe infections due to *Candida albicans* prompts me to record a case of actinomycosis in which the drug was successfully used.

A married woman, aged 40, consulted me in July, 1952, on account of pain in the left hypochondrium for which no immediate cause could be found, although in the past she had suffered from anæmia and dyspepsia, and also pyelitis due to *Escherichia coli* and associated with slight one-sided hydronephrosis.

About eight weeks after she was first seen a painful swelling developed over the left ribs which had the characteristics of a cold abscess and was suspected of being tuberculous. As the swelling did not resolve it was ultimately explored, a small amount of grumous material evacuated, and the wound closed without drainage; no tubercle bacilli or other microbes could be identified in the material removed. A low-grade fever persisted and she remained generally ill. A month after the operation the wound broke down and a small amount of purulent discharge appeared which on two occasions contained the characteristic golden yellow granules of actinomycosis. Through an unfortunate hitch these granules were not cultured, but the true nature of her long illness was now obvious.

During the latter part of 1952 she was still very ill with general malaise, fever, cough, and foul sputum, with occasional hæmoptysis. X-ray examination of her chest showed some mottling of the left base with collapse, and the appearances suggested actinomycosis. She also had an indurated mass on the right side of the pelvis and a similar one in the left hypochondrium.

Once the correct diagnosis was made she was treated continuously for ten months with massive doses of penicillin and iodides, without appreciable effect. Towards the end of 1953, over a year after she was first seen, her general condition was so grave that it was considered by all concerned that no further treatment was practicable.

Because of the known in vitro action of hydroxystilbamidine on this type of organism it was decided to try the drug, so in December, 1953, she received ten daily injections of 225 mg. each intravenously dissolved in 10 ml. of distilled water, and later after a pause of three weeks in January, 1954, she had a similar course which was equally well tolerated. After this treatment began her temperature fell and her condition improved steadily until the end of the second course, by which time it was apparent that her main infection had been mastered. Unfortunately in February, 1954, a small abscess suddenly developed over the right ilium, which pointed and was opened; only *Staphylococcus aureus* was identified from the pus, and after a course of aureomycin her temperature fell and the local condition cleared up.

Following the new treatment the general improvement in her condition was astonishing and now, a year later, she has put on 3 stone in weight and can do a full day's work. No physical signs remain.

The history of this patient emphasises once again how the pleomorphic lesions of actinomycosis make precise diagnosis in its early stages so difficult; it may not be until there is a dramatic event, such as the production of the characteristic pus from a surface lesion, that the diagnosis is confirmed, however much it may have been suspected.

---

[1] See *Lancet*, 1954, ii, 800.

Some cases show a partial response to iodides and penicillin in their early stages, but abdominal infections generally relapse, unlike infections around the jaw In 1939 I treated with iodides a case in which the cervical lymph-glands on one side were chiefly involved, the patient is still alive and free from symptoms In the patient I have now described, modern conventional treatment had little or no effect on the course of the disease, so it is all the more striking how two fairly short courses of hydroxystilbamidine brought the whole disease to a standstill except for the final incident of the superficial staphylococcal abscess, not an unusual event in chronic granulomatous conditions

The original source of the infection in this case may have been a young cat with discharging sinuses round the lower jaw which refused to heal The animal was destroyed without an exact diagnosis being made

TREATMENT OF CHRONIC AMŒBIC DYSENTERY

SIR,—Although Dr Andrade (March 26) feels it is a misapprehension, destruction of cysts is an important aim in the treatment of amœbic dysentery especially if the disease is to be eradicated

It is common experience that treatment aimed at destruction of amœbæ or the cysts singly does not eradicate amœbic dysentery in all cases, but combined treatment more often does so Relapses with an amœbicidal drug like emetine are all too common, and carbarzone by itself will not satisfactorily cure amœbic dysentery It appears that unless both cysts and amœbæ are destroyed some of the cysts may develop into amœbæ before they are excreted and thus restart the infection This could be avoided by prolonging the course of the amœbicidal drug indefinitely, but in practice this is not possible because either the drug is too toxic or the amœbæ become too resistant to it Hence the necessity for combined treatment

It is hardly accurate to call the cysts harmless Their harmlessness either to the host or, through contamination, to the contacts cannot be guaranteed

NON-PROGRESSIVE BREAST CANCERS

SIR,—I beg leave to make a correction of a point in my letter of May 14 My colleagues have shown me that, in attempting to adjust for the contribution which non-progressive lesions in stage 1 make to the five year survival-rates of various series (in the third paragraph of my letter), I made a fundamental error That error accounts for what appeared to be the close approximation of the net five year survival rates to what might be found in untreated lethal breast cancers I must, therefore, withdraw unconditionally that part of my letter dealing with that fallacious adjustment I think, however, that the other evidence, in itself, is sufficient to establish the non progressive character of the majority of stage-1 cancers

It is opportune now to quote the recent summary statement, among others, of Dr George Crile, jun, of the Cleveland Clinic Foundation "All evidence points to biologic predetermination and resistance of the host as the most important factors in the survival of patients with cancer of the breast [1]" And, in commenting on Crile's criticism of some radical surgery, Dr Morris Fishbein says [1] "This view is based on honest recognition of our lack of knowledge or of certainty in distinguishing inoperable cancers from those that are operable"

HEREDITY AND RHEUMATIC FEVER

SIR,—I should like to comment on one or two points in your annotation of March 5

You say that the children in our study [1] came from families of satisfactory economic status, and were in consequence not universally exposed to hæmolytic streptococcal infection But in fact they attended public schools and were not segregated, and Epstein [2] found that the incidence of respiratory infections was the same in the susceptible as in the non susceptible families.

We have not noted a decline in rheumatic fever among our patients A comparative analysis of the recurrence-rates during the past ten years has not revealed any significant difference from that observed in the previous ten years In addition, comparison of the incidence of severity, and of the duration of active carditis, during the years 1930–55, revealed a remarkable constancy

Diagnostic criteria undoubtedly vary from place to place However, the limited value of the postero-anterior radiographic view is now widely recognised, and the additional information afforded by examination in the oblique position should make comparisons more legitimate

We certainly expect some additional cases in the years to come, but since the size of our families will also probably increase, the predictions are unlikely to be altered significantly This was found to be true in the follow-up of our first series of families [3]

MAY G WILSON.

PROFESSIONAL SECRECY

SIR,—My attention has been drawn to a communication [4] from the Ministry of Health, dated May 10, 1955, addressed to regional hospital boards and hospital management committees concerning carnal knowledge of mental defectives This memorandum describes the new procedure to be adopted when a certified mental defective is found to be pregnant, or there is reason to think that sexual intercourse has taken place

A previous memorandum on this subject advised that a report should be submitted to the Board of Control, but that the local police should not be informed The new memorandum repeats the advice of reporting the facts to the Board of Control but reverses the advice on communication with the police It states that "the Ministry is of opinion that it is desirable that in future such cases should be reported to the Police not necessarily with a view to prosecution but to enable the Police in consultation with the Medical Superintendent to decide what is the best course to take in all the circumstances" It concludes that medical superintendents should send reports to the local chief constable even where the offence has been committed in another police area

The current policy of the British Medical Association concerning professional secrecy is expressed in the following terms

> "It is a practitioner's obligation to observe strictly the rule of professional secrecy by refraining from disclosing voluntarily without the consent of the patient (save with statutory sanction) to any third party information which he has learnt in his professional relationship with the patient"

Unfortunately the advice now tendered by the Ministry of Health has apparently been prepared and issued without any prior consultation with the British Medical Association or any of the defence bodies who are materially interested in this matter for the protection of their members Furthermore reasons have not been advanced to justify the change of advice and the abroga-

4 H.M (55)46

ion of the rule of professional secrecy in the case of mental defectives.

There may well be occasions when it would be fitting and proper for the police to intervene by the institution of legal proceedings against a suspected offender and there may also be sound reasons in law for issuing the advice described above. I feel, however, that before a change of this order is sponsored by official Governmental departments relating to an important ethical tenet the least that the Association could expect would be a communication from the parties who propose an alteration setting out their reasons and any legal sanction that might be invoked for their support. I hope that opportunity will be afforded in the near future for representatives of the Association and of the Ministry to meet to discuss the situation created by the issue of the memorandum.

ESTIMATION OF BLOOD-LOSS

SIR,—Your editorial of May 14 on the difficulty of estimating accurately the amount of blood lost at operation or as a result of trauma was excellent—until its close. Having rightly stressed that blood loss is usually underestimated, you continue: "... there is still insufficient evidence to justify the very large transfusions of blood recommended by Prentice et al. Early surgical treatment should be combined with rapid transfusion of enough blood to maintain the blood-pressure within normal limits." But one of the reasons that Prentice et al. gave these very large quantities of blood was to do this very thing. And surely the fallacy of relying only on the blood-pressure as a measure of circulatory normality is the reason why blood loss is so frequently underestimated. This recurrent canard is continually being shot down, and some of the best shots are included in the references to your editorial. These references point out that a loss of blood volume of up to 2 litres can be associated with a normal blood pressure. They point out that such patients are liable to develop alarming and sometimes lethal falls of blood pressure under anæsthesia, and there is also evidence that they are liable to develop acute anuria.

The temperature and colour of the nose and extremities and the size of the subcutaneous veins are far better clinical indications of the normality of blood flow than is the blood pressure. Prentice and his colleagues were aware of these facts, which is another reason why they gave such large quantities of blood. Finally, the group which they transfused included many suffering from multiple gunshot wounds which continued to bleed until and during operation. It is unfair to criticise the quantity of blood (10–20 litres) found necessary in these cases, by contrasting them with the amounts found to be adequate for civilian casualties with closed injuries or a single open lesion.

H. E. DE WARDENER.

CORPORAL PUNISHMENT IN SCHOOL

SIR,—Dr Jackson's letter of May 14 sponsors a point of view that has been carried to absurd and dangerous extremes in the United States. Without commenting upon his *gestalt* theories I feel compelled to warn British readers that the "permissive" attitude can lead to serious lowering of intellectual and moral standards in schools.

A Californian teacher has recently been discharged not for using corporal punishment, but for teaching reading by "traditional" instead of "progressive" method. He testified that fourth grade children do not know the alphabet, and that when he attempted to teach the multiplication tables by drills he was rebuked by a superior. The teacher was not allowed to discipline a boy who called him obscene names for three months. Another teacher was not allowed to punish a child who attacked her and broke her nose. The "progressive" school authorities would not listen when these and other teachers sought disciplinary measures.

Dr Jackson's *gestalt* theories lead him to believe that punishment will render children susceptible to illness. Years of experience with "progressive education" convince me that lack of intellectual and moral discipline can be a serious danger to children, to the community, and, ultimately, to the survival of all civilised values.

RONALD W. ANGEL.

ADENOSINE TRIPHOSPHATE IN PAROXYSMAL TACHYCARDIA

SIR,—In 1929 Drury and Szent-Györgyi[1] pointed out that adenosine triphosphate (A.T.P.), adenosine monophosphate (A.M.P.), and adenosine dilated the coronary arteries and slowed atrioventricular conduction. The work of Green,[2] Bielschowsky et al.,[3] and others made it clear that these substances act by inducing a "shock" comparable to that produced under certain conditions by histamine, adrenaline, or insulin. Moreover, it was found that the adenyl root is responsible for the vasodepressor effect, while the pyrophosphate is the shock-inducing factor in A.T.P.; also that magnesium phosphate is the most active shock-inducing member of this group of substances.

Accordingly I have tried, over the past ten years, to bring about the cessation of paroxysmal tachycardia by producing a mitigated shock with intravenous adenosine triphosphate. 18–20 seconds after an intravenous injection (given as rapidly as possible) of 2 ml. (20 mg.) of A.T.P. complete asystole lasting 2–4 seconds usually ensues. This asystole is sometimes interrupted by ventricular extrasystoles originating from various foci or by isolated auricular contractions. In these circumstances the patient is asked to swallow once or twice, and subsequently he reports with relief that his galloping heart action has slowed down. The electrocardiogram (E.C.G.) shows a nodal impulse formation for 3–4 complexes or, after a few atypical auricular ventricular complexes, transitional auricle activity without ventricular stoppage. Subsequently regular sinus rhythm is established, differing from normal rhythm only in that the conduction time from auricle to ventricle is longer; but after 3–4 complexes this too returns to normal.

Judging from the E.C.G. changes during the injection there seems no doubt that the A.T.P. substances arrest the heart action and temporarily cause complete asystole. While the impulse formation is slowly recovering they inhibit impulse conduction and so prevent recurrence of the paroxysmal tachycardia.

The effective dose is 20 mg. (2 ml.), provided that the vein is sufficiently wide to allow rapid injection. If the veins are thin and weak walled, I administer 30 mg. at the outset. In no case have I observed any toxic side-effects. Since the effect is due to the high blood level, intramuscular injection is unsuitable.

In 1947 I reported 90 onsets successfully treated in this way,[4] and in 1949 an additional 118 onsets.[5] Komor and Garai[6] last year reported success in 250 episodes among 50 patients.

The response of supraventricular paroxysmal tachycardia to adenosine triphosphate is so striking that it may be taken as one of the chief criteria in the diagnosis of the condition.

FEAR OF CANCER

SIR,—I read with interest Mr Donaldson's article in your issue of May 7, and I should like to mention two aspects of the fear of cancer which add, I believe, in many instances not inconsiderably to the mental suffering of patients and to the distress of those around them These apprehensions are that cancer is contagious and, again, that it forbodes malignancy in the offspring

In the case of a man who was under my care some years ago the differential diagnosis between bronchial carcinoma and lung abscess could not be settled The patient's wife asked whether it was necessary for her to take precautions in case the illness proved to be cancer I told her that cancer was not contagious, but she was unconvinced When the patient died his wife was the first to speak about a postmortem examination, and on hearing that an abscess had been found in the lung, but no cancer, her face lit up with relief and she exclaimed "Thank God for that"

I am inclined to think the belief that cancer is infectious is a widespread and deeply rooted one It may be thought of as a modern version of man's primitive response to dangerous illness against which he used to protect himself by the system of taboo Since this system has no currency in advanced society, *tendencies* of avoidance entering into the attitudes towards the sufferer are bound to impart a sense of guilt which cannot but render the relation to him a conflicting one For his part, the sufferer who, of course, shares in the notions of the undeclared taboo senses his position as that of a fear-arousing outcast Here Mr Donaldson's personal experiences provide a telling illustration of how, in keeping with the rules of taboo, even the mention or alone the thought of cancer come under the restrictions of the ban

The notion of cancer heredity, looked at as an irrational belief, may be only an extension of the idea of its infectiousness

JOSEPH ZELMANOWITS

MEDICAL TELEVISION PROGRAMMES

SIR,—We are sorry that Mr Welsh (May 14) was revolted by the television programme of May 2 on *Mind and Body* Human physiological demonstrations can only be made on living subjects In this programme all three subjects were professional associates of the doctors taking part We fail to see how the first two simple demonstrations of physiological response to stress could appear revolting The cigarette "burn" was used to demonstrate that the physiological response to a threat can be greater than the stimulus itself The "burn" was not only suggested as a suitable stimulus by the subject (himself a doctor) but was accepted by him quite willingly on a number of occasions during rehearsals Of course the only contact made was a light touch, producing no more than erythema

Some people have reported to us that they themselves experienced a feeling of mounting tension whilst observing the threat, and it is clear that it was this communicated anxiety that they found disturbing We have yet to meet anyone to whom it had even occurred that "sadism" was a motive in presentation, and perhaps if he had not switched off at a crucial moment Mr Welsh would not have retained a distorted impression

To judge by correspondence received by the B B C, there has been no general adverse public reaction Indeed, two general practitioners have reported to us that, since viewing the programme, patients of theirs have been able to accept the emotional basis of some of their somatic symptoms and have requested psychological help

The educational value of television programmes on appropriate medical subjects has recently been referred to in your columns,[1] and we hope that the B B C will continue to present interesting and useful medical programmes The technique is still developing and we feel that much remains to be learnt about the proper balance between demonstration and explanation necessary to avoid misinterpretation

In order that, as broadcasters, we may continue to maintain our anonymity we sign ourselves,

Dr A, Dr B, and Dr C

TOXIC EFFECTS OF RESERPINE

SIR,—We read with interest the letter from Dr Stead and Dr Wing in your issue of April 16 on the toxic effects of reserpine They describe two cases of parkinsonism developing during treatment with large doses, but they suggest that toxic effects are slight with small doses

In our experience of mentally ill patients treated on dosage of 0 5–2 mg daily, side effects may be troublesome The degree of disturbance varies widely but is generally greater in the neurotic than in the psychotic Drowsiness, loss of energy, nasal stuffiness, and tremor are commonest, and are most marked at the end of the first and during the second weeks of treatment Aches in the limbs occur infrequently Unless warned of these effects, many outpatients may stop the drug before there is any chance of benefit Wilkins[1] has reported the development of agitated depression in cases of hypertension treated with reserpine

Frequently the side effects may so add to the burden of the patient with endogenous depression, that admission to hospital may be necessary We feel that in these cases the drug is contra-indicated We have noted the development of parkinsonism in some cases treated with oral dosage of 4–8 mg daily for one to three months Facial immobility and restlessness are common on this dosage Elderly patients may easily become tremulous and unsteady with consequent danger of fractures Frequency of micturition is fairly common and nocturnal incontinence of urine has been noted in some cases Increase in dreams pleasant or unpleasant sometimes occurs Kline has reported that 2% of patients treated with reserpine have epileptic convulsions for the first time, but we have not observed this in any case

Our experience with parenteral reserpine has been mostly in a series of 25 inpatients who were given 10 mg intramuscularly and 3 mg orally daily for three to seven weeks. Drowsiness, loss of energy, nasal stuffiness and restlessness occur in every patient to some degree Drowsiness may be so bad that most of the day is spent in bed. Nasal congestion may be complicated by nose bleeds or much less commonly by necrosis of nasal mucosa or sinusitis or headaches possibly due to vacuum changes in the sinuses Breathlessness and a sensation of smothering may occur Restlessness may reach a degree in which rest is unattainable without heavy sedation and may bring about impulsive behaviour Impaired mobility of facial expression and increased salivation are common Parkinsonism to the degree described by Wing and Stead has been noted in 5 of the series

Kline[2] does not consider this a contra indication to continued treatment and in this we concur Reduction of the intramuscular dosage to 5 mg daily usually provides relief when the patient is unable to get about freely or to feed himself Sometimes the patients complain of pain in the back of the neck or in the lumbar region, or of aches in the limbs Appetite is usually increased, but where side effects are marked may be greatly reduced We have noted also in individual cases postural hypotension and unexplained œdema of the feet and ankles Delay in initiating micturition and impairment of accommodation may occur to a minor degree The 10 mg injection is 4 ml in volume and is frequently painful

It is evident that parenteral reserpine therapy in this dosage can be a very unpleasant treatment We hope that modifications in the régime will make it less [illegible] Patients require frequent encouragement and explanation Adjustment of dosage is fairly often necessary

---

1 Wilkins, R. W *Ann N Y Acad Sci* 1954, 59, 36
2 Kline N S Address to American Psychiatric Association, Berkeley, California, Dec. 30, 1954

We have found barbiturates best in the control of restlessness, an 'Antistin Privine' nebuliser for nasal congestion and a belladonna mixture for excessive salivation. Despite these disadvantages our results have been such as to encourage us to continue trial of the drug.

We are indebted to Ciba Laboratories Ltd. for supplies of reserpine in the form of 'Serpasil' and for supplies of 'Antistin Privine.'

CORTISONE, CORTICOTROPHIN, AND INFECTION

SIR,—The most enlightening paper by Dr Shaper and Dr Dyson (April 30) prompts me to draw attention to the relationship of an allied drug (hydrocortisone) to infection. In view of the increasing popularity of the use of hydrocortisone in local treatment of joint and soft tissue lesions it may be timely to report a case of suppurative arthritis after an intra-articular hydrocortisone injection.

A woman of 75 was admitted to hospital with an infective arthritis of her knee. She gave a six weeks' history of general malaise followed by pain and swelling of her right knee. Two weeks before admission she attended the outpatient department of another hospital where physiotherapy was ordered and hydrocortisone was injected into the knee-joint. Following this her condition deteriorated.

On admission she had a mild pyrexia and a moderate effusion in the knee joint with restricted movements. Thick pus was obtained on aspiration of the joint, which had to be incised. The culture yielded a profuse growth of penicillin-sensitive pneumococci. The infection subsided completely with local and systemic penicillin.

There are three possible causes of the joint infection:

(1) She had a pneumococcal lung infection with secondary pneumococcal arthritis, the hydrocortisone causing the latter to flare up.

(2) The knee condition was an exacerbation of an osteo-arthritis and the pneumococci were introduced during the hydrocortisone injection (unlikely).

(3) She had a non-specific "toxic" synovitis following pneumonia. The trauma of the injection and the hydrocortisone in the joint caused a *locus minoris resistentiae* and the deposition of pneumococci in the joint.

The first is the most likely explanation, but if the last be true intra-articular hydrocortisone should be contra-indicated not only in an infective joint lesion but also in the presence of an infective focus elsewhere.

Bebington, Cheshire

E H STRACH.

STAPHYLOCOCCAL INFECTION IN THE NEWBORN

SIR,—I have followed the recent correspondence with interest and I note that Dr Forfar and his colleagues (May 21) have now referred to what are probably the most important aspects—namely, the unsuspected pathogenicity and the prevention of staphylococcal infections in the newborn. That certain staphylococci can be dangerous was realised last century when Ogston, the illustrious discoverer of the organism, suffered from a lung abscess which yielded a pure culture of staphylococci. His remark that he had hitherto regarded the staphylococcus as a "friendly little chap" is still echoed today. The unfriendly strains can now be differentiated with reasonable accuracy by phage-typing, but it must be confessed that facilities for typing are not readily available to everyone investigating staphylococcal outbreaks. This is particularly unfortunate since it makes it impossible to confirm the route of infection.

Dr Forfar and his colleagues rightly suspect that the new arrival in the household may introduce a virulent (and resistant) organism acquired in the maternity hospital. Within twenty-four hours of its residence in the hospital nursery the infant acquires the flora and fauna of its fellows, and it is capable of infecting the mother's breast with any pathogenic staphylococci present in its nasopharynx. The evidence of this has been conclusively demonstrated by Colbeck[1] and confirmed by Isbister.[2] I am indebted to these investigators for their personal communications which solved the problem of why the incidence of mastitis was infinitely higher in mothers who had been confined in the Burgh maternity hospital than in those confined at home. It is probable that a household may become tolerant of its own domestic strain of the staphylococcus without developing any resistance to others.

That is why congregation in hospitals carries such risks and why the nursery—where such still exists—is the danger spot, nullifying as it must the most rigid precautions applied to the mother alone.

While I endorse the first part of Dr Forfar's remark that "prevention, not treatment, of neonatal staphylococcal infection must be the ultimate goal," but as yet that appears to be unattainable, I think that he might be disposed to amend the latter part after he has put into practice the principle of strict cubicle isolation of the mother *with* her infant.

Health and Welfare Department,
Kirkcaldy

J R W HAY

HASHIMOTO'S STRUMA LYMPHOMATOSA AND RIEDEL'S THYROIDITIS TREATED BY RADIUM

SIR,—I was interested to read that Dr Cooke and Dr Luxton (May 7) "have studied about 25 patients, in nearly two-thirds of whom the diagnosis has been confirmed by histological section," "that not infrequently the patient first visits her doctor for symptoms not quickly ascribed to thyroid disturbance, such as lassitude, muscle and joint pains, increasing weight, and changed facial appearance," and that "the efficacy of modern treatment by oral dried thyroid emphasises the need for the diagnosis of Hashimoto's disease to be considered more readily." I was particularly interested in their remark that "one of our patients, observed for seven years, now has a liver which is greatly enlarged."

In a paper[3] in 1938 by J Mill Renton and A A Charteris I contributed to a report on 5 cases which had been treated successfully with radium (1800r–4000r) and remained well, to the time of reporting, for from two to five years. Of these 5 cases 3 were diagnosed on histological evidence and 2 on clinical and therapeutic grounds, the response to radium being so astonishingly rapid, without local or general reaction, and quite unlike that given by any other condition.

Our definition of Riedel's thyroiditis included "struma lymphomatosa" and "lymphadenoid goitre," and our cases 1 and 4 were of this state confirmed histologically. They were middle-aged women who complained of discomfort and swelling in the neck with dysphonia and dysphagia; tissue was removed from the isthmus of the gland. Following a mistaken histological diagnosis of malignancy in case 1 a radium collar was applied (2500r) and within ten days the patient was symptom-free and within thirteen days the thyroid swelling had gone. On account of such favourable and ready response 3 other cases were treated with radium; in 2 a biopsy specimen was taken, but in 1 treatment was begun after a clinical diagnosis of Riedel's thyroiditis had been made, and a like response to radium was considered *diagnostic*.

The 5th case was culled from the records, having been diagnosed clinically as thyroid carcinoma and given a palliative dose of radium estimated to be 1800r. She showed great improvement of voice, and the neck swelling subsided at the end of a week. As she was alive and well almost five years later, when we reviewed the hospital records prior to publication, she was considered to have suffered from Riedel's thyroiditis.

---

1. Colbeck, J. C. *Canad med Ass J* 1949, 61, 557
2. Isbister, C. *Med J Aust* 1954, ii, 801
3. *Brit J Surg* 1938, 26, 31

These patients all remained well for many years and none showed any signs of thyroid deficiency We considered that the radiation destroyed the lymphocytes and germ centres that form in the thyroid gland and infiltrate the overlying muscles, and that the thyroid tissue, having been overrun by these cells and become atrophic, had regenerated satisfactorily, from the absence of later pressure effects we concluded that fibrosis had not occurred

The late results of the cases have been given me by Dr Charteris, of the Western Infirmary, Glasgow, from his follow up notes, and the short series in brief is

Age	*Variety*	*Treated*	*Result*
39	Hashimoto	1933	Well for at least 18 yr
50	Riedel	1934	Well for 19 yr
49	Riedel (clinical diagnosis)	1935	Well for 15 yr
43	Hashimoto	1937	Well for 18 yr
72	Thyroid carcinoma (clinical diagnoses)	1933	Well for 20 yr (Died at 92 of senile vascular disease)

Although we were unable to contribute to an understanding of the ætiology of the condition, we reported a simple and harmless diagnostic test which is also an effective therapeutic measure

North Middlesex Hospital,
London, N 18 J F HEGGIE

HYDROCORTISONE OINTMENT

SIR,—I was most impressed by the account in your issue of May 21 by Dr Brian Russell and his co-workers of their valuation of hydrocortisone ointment in the treatment of various pruritic dermatoses. Dr Russell and his team are to be congratulated on their scientific method of approaching the problem, and for the clarity of their results, which showed in which conditions the use of hydrocortisone ointment is indicated

It is interesting to note that these appear to be mainly those classified in Sneddon's[1] group 2—"dermatoses with a large psychogenic factor"—and, as I have written elsewhere,[2] it is of the utmost importance that any underlying emotional (or psychogenic) factors be carefully sought out and discussed with the patient, in addition to local or symptomatic treatment

This does not detract from the usefulness of hydrocortisone ointment, however, and I hope that it will very soon be available for those patients remaining under the care of their general practitioners as well as for those who are referred to hospital outpatient departments

London N W 3 PHILIP HOPKINS

THE CARAVAN SITE

SIR,—May I comment briefly upon one of the points discussed in your article of April 30 (p 924)?

You refer to control of caravan sites, and state that "it is better that the site owner should run his own business in an orderly and efficient way than to make bad laws to suit hard cases" I accept this platitude, but why should new laws be "bad laws"? What happens when the site owner fails to run his business in an orderly and efficient way? The health of the community is at stake Why should owners of badly managed, unhygienic sites be unchecked? Should we wait until news of a dysentery-typhoid outbreak strikes the headlines and then, deploring this unfortunate occurrence, assure the public that every possible effort is being made to limit the spread of infection? Surely, if caravan sites can be made into healthy and attractive holiday centres, which I believe practicable, slum conditions should no longer be tolerated Taking into consideration the present high rate of caravan production, I believe the negative policy of *laissez-faire* is likely to lead to the situation getting completely out of hand

Good sites should be encouraged by every possible means They are entitled to get a reasonable financial return for their outlay and expenditure in building up and maintaining high standards and should not necessarily have their activities curtailed in the winter months. The neglected sites, if they fail to raise their standards should be subjected to slum clearance

For the reasons detailed in my article[1] I consider that amendment of the Public Health Act, 1936, is essential

Newcastle upon Tyne WILLIAM HUNTER

A VISIT TO KOLTUSHI

SIR —I should like to reassure Dr Mungo Douglas (May 21) that I do not wish to dispute the discovery to which he alludes, although I must confess I was unable to grasp its meaning Since it prevents disturbances of gastric function, bronchospasm, and schizophrenia, one awaits confirmation with interest However, the purpose of my letter was to object to vague disparaging remarks about the work of Pavlov which, in my opinion, holds promise of clinical application in such diverse fields of medicine as indicated by the three disturbances mentioned at random If Pavlov was unaware of the work of Mr Alexander it may be regrettable, but it does not invalidate Pavlov's theories or, still less, his experimental findings However notable the claimed discovery may prove to be, it does not excuse the use of disparaging remarks about the work of others unless such remarks can be substantiated by demonstration of specific errors of scientific fact

Sheffield C H FOGGITT

CLINICAL STAGING OF CARCINOMA OF THE BREAST

SIR,—I would be grateful if you would allow me to comment upon the response to my letter in your issue of March 26 and in the *British Medical Journal* of the same week A copy of the letter and a covering note were sent to a surgeon and a radiotherapist at each of the teaching hospitals in Great Britain and to a number of interested clinicians In all, 65 people were written to and I asked not only for their personal views but suggested that they might feel inclined to bring the matter forward for discussion at their hospital medical committees 43 replied, with varying degrees of enthusiasm, that they favoured the plan to establish an international staging and wished me luck, though several said it would be an uphill struggle 2 said it was hopeless trying and 1 said the attempt should not be made at all The opinions most frequently expressed were that the British Empire Cancer Campaign, the Royal College of Surgeons, and the Faculty of Radiologists were the most appropriate bodies to deal with the matter Mr Blaikley (April 16) has informed your readers (and this has also been pointed out to me by individual correspondents as well as by the reports from medical committees which are beginning to reach me) that a committee of the General Register Office under the chairmanship of Dr A H T Robb-Smith is considering this subject at the moment

It seems, therefore, that the problem is actively exercising learned opinion and it is certainly not the wish of my colleagues at the Royal Marsden Hospital, on whose behalf I first wrote, to complicate the issue further at present

I think it is generally agreed that any staging must be clinical although, as Dr Bloom and Dr Richardson point out,[2] a pathological staging of the regional lymph nodes is much more accurate But it is a fact that this information is not available in a high proportion of the cases, and their graph indicates that within each clinical stage what one loses in pathological grade 3 cases one gains in grade 1 cases My personal view is that staging should only be clinical but that in the presentation of results the histology should also be considered when this is known Dr Robert Morrison s staging[3] employing as it does eleven groups, looks complex but is in fact an application of the TNM system which will undoubtedly form the basis of any international staging not only for cancer of the breast but for other sites as well I feel confident myself that an acceptable staging will emerge in the not too distant future

REACTION TO VITAMIN B_{12}

SIR —I read with interest the account by Dr Gillhespy of a patient in whom an injection of vitamin B_{12} produced an anaphylactoid reaction with urticaria of the skin

In 1952 I reported[4] that whereas side-effects occasionally occurred following the administration of certain preparations of vitamin B_{12} derived from cultures of *Streptomyces griseus* there were no adverse reactions to a preparation of vitamin B_{12} derived from liver

It would be of interest to know the nature of the vitamin B_{12} preparation which produced the sensitivity reaction in Dr Gillhespy s patient

Cowley Road Hospital
Oxford. P D BEDFORD

INFORMATION FROM HOSPITAL

SIR,—Working in the vicinity of several of the teaching hospitals I am impressed by the frequent complaints from relatives of inpatients and from outpatients themselves that they find it almost impossible to obtain adequate information from the hospital about their progress and about the proposed investigations and treatment Whilst I always find house officers extremely cooperative when asked for information over the telephone this is a time-consuming business both for them and for me

Would it be worth appointing a general practitioner to each large hospital whose sole and very much full time function would be to act as a medical liaison and information officer and who would always be available to those patients, relatives and general practitioners in the district needing immediate clinical details rather than the usual nurse s bulletin ?

London S W 7 BENJAMIN LEE.

DRUGS IN THE TREATMENT OF DEPRESSION

SIR —Your annotation of May 21 does not mention opium I think this is still a valuable drug in the treatment of minor depressive syndromes many of them with anxiety, which are so commonly seen in psychiatric outpatient practice It may be dispensed in the form of a mixture containing 10 minims of tincture of opium (B P) to the half ounce of chloroform water (its constipating effect being offset by the addition of a few minims of liquid extract of cascara) taken thrice daily Its soothing effect is as great as that of the barbiturates though not produced so rapidly

I have been prescribing a mixture of this kind for many years. I have never seen a patient become addicted to it (it is extremely unpleasant to take) and only once to my knowledge has a patient attempted to use it for ostensible suicidal purposes. He swallowed an estimated quantity of six ounces of the mixture slept for about fourteen hours, and woke up feeling better than he had done for months.

Considering too the ease with which patients may hoard barbiturate tablets or capsules and the frequency with which they are used in suicidal attempts, I think there is still much to be said for the old fashioned opium mixture Dispensed in the strength I have mentioned the mixture is not subject to the Dangerous Drugs Regulations It can be used safely for many weeks at a time and it goes well with the amphetamine group of drugs I have generally found that it is only when insomnia is severe that it is necessary to add a nocturnal barbiturate to this régime

REGISTRARS AND REGISTRARS

SIR —If for some my letter of April 23 expressed malevolence I can only retort as did the mediocre marksman at the firing point Well Sarge it left here alright !" A Letter to the Editor may appear in various styles and if a correspondent thinks it more effective to make his point with very obvious exaggeration and a bit of fun poking surely it is in accordance with accepted practice—particularly if the subject is a political one

May I take the opportunity of repeating the previous theme that registrars at the periphery—registrars (P) if you like—deserve far more encouragement

REGISTRAR (W PLUS)

METCHNIKOFF, LISTER, AND EHRLICH

Dr Leonard Crome honorary secretary of the medic committee of the Society for Cultural Relations with th U S S R (14, K[illegible]on Square London W 8) writes

A requ[illegible]come to the Society from the Metchnikoff Museum in [illegible] U.S.S.R for information concerning the whereabouts of letters from Metchnikoff to Lord Lister and Paul Ehrlich We should be most grateful if any of yo readers could help us to trace these letters.

Medicine and the Law

Damages for Rheumatoid Arthritis

A Scottish school teacher has been awarded £20 damages against her employers the Glasgow Corporati for rheumatoid arthritis contracted through working unhealthy conditions[1]

The plaintiff a woman aged 28 averred that as a result s had become unfit for her professional duties and claim £10 000 damages. She said that the classroom in which s taught was badly ventilated and inadequately heated T corporation maintained that the room was not in an unhealt or dangerous condition and called medical evidence to t effect that conditions of damp and cold had no relevance considering the cause or aggravation of rheumatoid arthrit

The judge in summing up told the jury that there we three questions which they must decide The first w whether they held it proved on the evidence that the plaintiff teaching place was cold damp and ill ventilated throughou the whole period of two and a half years that she was ther If they were not satisfied that the room was unduly cold damp during that period then they must find for t defendants. If they were satisfied that the room was undu cold and damp then they must consider whether th conditions caused or aggravated the rheumatoid arthri from which the plaintiff suffered. The third question w whether the development of rheumatoid arthritis in t plaintiff was something that the defendants should ha anticipated from the exposure of the plaintiff to the conditio in the room. The law required that the plaintiff must pro that the defendants as ordinary reasonable people ought have anticipated and foreseen that if she was exposed to w and cold conditions rheumatoid arthritis was likely to caused or aggravated

The jury by a majority of seven to five found for t plaintiff on these three points and assessed the damages £*000

It is not yet known whether the corporation intend appeal This case is clearly of unusual interest

Obituary

DONALD YOUNG SOLANDT

M A, M D Toronto, Ph D Lond, D P H, F R.S (C)

Dr Solandt, professor and head of the department of physiological hygiene and professor of physiology in the University of Toronto, died on March 30 at the age of 48

He was born in Ottawa, Ontario, the son of the late Donald McKillop Solandt, D D He entered the University of Toronto in 1925, and after taking his M A in physiology he graduated in medicine in 1933 His keen interest in biophysical research led him to postgraduate work in the University of Pennsylvania and later in England, where he obtained a PH D degree from the University of London in 1936

On his return to the University of Toronto in 1936 he took up his duties as assistant professor of physiology, and in 1939 he was appointed associate professor and two years later to the chair of physiological hygiene He retained his appointment in physiology where he was in charge of the section of biophysics During the late war he served as surgeon commander in the medical esearch division of the Royal Canadian Navy, where he was responsible for many valuable researches on vision nd hearing and related biophysical subjects In recognition of this work, particularly on the protection of ight vision, the United States government awarded him he *Medal of Freedom* with bronze palm

Dr Solandt served on advisory committees of the épartment of National Health, the National Research ouncil of Car da, and the American Public Health ssociation e was a fellow of the Royal Society of anada and member of many scientific societies in anada, th nited States, and England He was an norary ow of the American Medical Association s boc *Highways to Health* appeared in 1933, and cor ted many papers on medical and biophysical ep scientific journals, including several to our n the early 'forties describing experimental f the anticoagulants

R N, who worked with Solandt in Toronto before e war, recalls him as "at first sight a rather shy rsonality, and quiet in speech and manner However, is reserve was superficial and anyone who worked with n soon found that underneath was a warm and veable character His leanings were essentially biolysical, though he was interested in the physiological pects of all branches of medicine, and was always lling to try out any experiment He did much of his rly work at University College Hospital and always d a soft spot for England and welcomed any opporunity to visit it again His integrity and keen sense of umour will be missed by his many friends"

C H B, to whom we are indebted for this memoir, lds "The breadth of Dr Solandt's interests was a urce of constant amazement to all who knew him is extensive knowledge of literature, music, natural ience, and photography made him an exceptionally imulating companion In his passing the university s lost a man whose professional services in science and education have been of the highest value"

Dr Solandt is survived by his widow, the former rbara Garrard of London, and three daughters

CORNELIUS ALBERT GRIFFITHS

F R.C S

THE death of Mr Cornelius Griffiths, on May 7, at the e of 90 ends the career of the oldest and one of the ost notable Welsh surgeons

He was born at Merthyr in 1865 and he studied at e medical schools of Bristol and St Bartholomew's ospital He qualified in 1880 and, after holding a use-appointment at Bristol General Hospital, he became edical tutor in the Bristol Medical School In 1893 he ok the F R C S, and the same year went to Swansea R M O at the General Hospital The following year mov o Cardiff and, in due course he was appointed of Cardiff Royal Infirmary

es "His work was of an outstanding forty years, scores of doctors were taught admired his technique. They also will remember his unfailing good manners under any circumstances, and his kindness to the students in private. In his earlier years at Cardiff he was constantly operating in all the coal areas round the city, and, as there were no motor-cars or ambulances, and only limited hospital facilities, he often operated in lonely farm houses by candle-light on the kitchen table In his retirement he found relaxation in his favourite Usk fishing, and for several years he sat on the magisterial bench. To everyone he was affectionately known as 'Corny,' and there are many who think of him not only as a great surgeon, but as the gentlest of men"

JAMES RANDAL HUTCHINSON

M D Manc, D P H

Dr Hutchinson, who retired in 1947 after nearly forty years as an epidemiologist at the Ministry of Health and the Local Government Board, died on May 6 at the age of 75

Hutchinson was a north-countryman, blunt and direct of speech After a brilliant career at Owens College, Manchester, he graduated M B with honours in 1902 Almost at once he decided to specialise in public health and in 1904 he took the D P H. Four years later he became senior assistant to Dr James Niven, medical officer of health for Manchester Under Niven he acquired great experience in the investigation of outbreaks of epidemic disease, especially those of enteric fever, and the administration of anti tuberculosis measures in which his chief was a pioneer

In 1910 Hutchinson became M O H for Wigan, but Sir Arthur Newsholme, medical officer of the Local Government Board, already had an eye on this reliable young investigator, and on his recommendation in 1911 Hutchinson was appointed a medical inspector of the board. Here he worked under the direction of Colonel R J Reece and quickly gained a reputation as an epidemiologist During the first world war his many investigations helped to safeguard the country from the dangers of epidemic outbreaks In 1919 he became a medical officer of the Ministry of Health working in the branch dealing with sanitary administration in relation to infectious disease, again with Reece as his chief and later with Macewen

In 1926 the Minister of Health, with the Medical Research Council, appointed a committee of experts to inquire into the preparation and standardisation of vaccine lymph, the methods of vaccination to be used, and the possibilities of removing any of the risks attendant on vaccination As secretary of the committee, Hutchinson was largely responsible for the two reports published in 1928 and 1930 which did much to allay public anxiety as to the risks of encephalitis after vaccination. Later Hutchinson became deputy senior medical officer of the branch concerned with tuberculosis and epidemic diseases and during the late war he served at headquarters as a specialist medical officer in epidemic diseases When he reached the retiring age he was re-employed as a temporary medical officer in the Ministry, where his experience and advice were of great value Before his final retirement, he contributed to the *Chief Medical Officer's Report for 1945* a valuable historical note on the prevention of smallpox in England and the foundation of the Government Lymph Establishment

A. S MacN writes "Hutchinson was of medium height, of fair colouring, clean-shaven, and somewhat reserved in manner, a worker of regular hours, methodical, reliable, and industrious He had his individual characteristics Towards the end of May each year he would discard his bowler hat, don an old-fashioned straw boater, and wear an alpaca jacket in the office We always said we could date the onset of summer by Hutchinson. He was a great believer in field epidemiology, and at first resented the more predominant part now played by bacteriologists in investigation of disease outbreaks. When convinced of their value, there was no more loyal worker and collaborator in the Emergency Public Health Laboratory Service. He carried the experience and thorough standards of the medical department of the Local Government Board into a more hurried and restless age He elucidated many problems in epidemiology and public-health administration and his work will not be forgotten"

Dr Hutchinson is survived by his widow

WILLIAM MORTON ROBSON

M D Lond., F R.C.P

Dr Robson consulting physician to Northampton General Hospital, died on May 10, at the age of 77, at his Northampton home.

He was born in co Durham and he studied medicine at Guy's Hospital qualifying in 1901 After holding residential appointments in London he went to St Andrew's Hospital Northampton, in 1903 as junior medical officer By 1905 he had taken the M D (with gold medal) and M.R C.P , and had been appointed to the honorary post of assistant physician in charge of the electrical department at the Northampton General Hospital.

Later he became radiologist to the hospital as well as physician It was largely thanks to him that an anonymous donor gave much of the present X ray department to the hospital "He was a first-rate clinician," R. O L. writes, "which helped him greatly in his radiological work, and for many years he covered both diagnosis and therapy with remarkably good results His diagnostic reports notable for their brevity were always written by his own hand; in X ray therapy he followed closely the technique of Coutard and though his dosage by modern standards was often low his results were good and he seldom distressed patients by his treatment.

In 1920 Robson was elected F R.C P and soon afterwards he became senior physician to the hospital In his capacity he took his share of the committee and administrative work and was a powerful figure both upon the hospital board of management and upon its medical board.

E. H. S writes: " Widely respected both by his medical colleagues and also by the thousands who had been his patients, Dr Robson will perhaps be even better remembered by his work for the nurses much of which was done in his latter years. Always a champion of the nursing profession and a sturdy advocate of better conditions, he was largely instrumental in introducing a scheme for the training as nurses of ex tuberculous patients at Creaton Sanatorium, an institution of which he was a founder member In his later years nothing gave Dr Robson greater satisfaction than the progress of the Creaton scheme whereby a number of ex tuberculous patients were able to receive their T A training and eventually hold posts at the sanatorium

Until recently a keen field sportsman he was a notable fly fisherman and had a wide knowledge of country lore. Indoors he was more than a match for most at the card table, enjoyed (and was always able to furnish) excellent port, and was an entertaining and amusing raconteur Courtly in his manner shrewd in his judgment, combining a quiet sense of humour with a natural dignity he was widely known and universally respected in Northampton and district.

Dr. Robson leaves a widow and a daughter

OTTO ROSENHEIM

Ph.D Würzburg F R.S.

The death of Otto Rosenheim at the age of 84 recalls the many notable contributions which he made to physiological chemistry or what we now call biochemistry

He was born in Germany and after taking his degree at Würzburg he worked for a time with Graebe in Geneva. About 1895 he came to this country where he worked for a time in Manchester His first official appointment was as research assistant in pharmacological chemistry to F W Tunnicliffe at King's College London in 1901 but he had been associated earlier with Tunnicliffe in an investigation on uric acid salts and the volumetric estimation of this acid They demonstrated that the so-called quadriurates of Sir William Roberts were mixtures or solid solutions of uric acid and biurates. They were also associated in an investigation (published in *The Lancet* in 1901) of the possibility that selenium might be a source of toxicity of beer the selenium arising from the sulphuric acid used in the preparation of the sugars used in fermentation At this time too they studied the influence of formaldehyde in nutrition and they showed that 1 in 5000 in milk and 1 in 9000 in food had no effect on healthy children Rosenheim used this finding in after years when on his annual trips to t Continent, North Africa, and Mediterranean islands, took with him a supply of milk to which formaldehy had been added

While working on the estimation of formaldehyde milk he came to the conclusion that the Adamkiew reaction for proteins, used by Hopkins and Cole for th isolation of tryptophan, was not due to glyoxylic acid the acetic acid used but to formaldehyde and traces other necessary substances in the sulphuric acid use When Tunnicliffe left King's College, Rosenheim join Halliburton and was appointed lecturer in 1904 and lat assistant professor of physiology With Locke he devis a new perfusion method for the mammalian heart, usi dextrose in oxygenated Ringer solution and followed th sugar metabolism. But his main interest at this time w the study of the constituents of nervous tissue In 19 he had worked out methods for the detection of choli in the breakdown of nervous tissues; he then embark on a bold undertaking with Mary Christine Tebb who he later married—the study of the chemistry of protag extracted from brain Liebreich Gamgee Blankenhor and later Cramer believed this substance to be a sing chemical entity but Thudichum had shown it to a mixture as early as 1874

Rosenheim and Miss Tebb revealed how cold aceto removed cholesterol from dried brain and how acetone then extracted protagon which, by further treatment with solvents could be separated into t substances—phosphorus-free phrenosin and kerasin, a phosphorus-containing residue containing sphin myelin Later Rosenheim improved the preparation these galactosides by extraction with pyridine and fin arrived at tentative structures for phrenosin and kera To lay the ghost of protagon had involved some extrem difficult and laborious manipulative chemistry and recognition of his contribution Rosenheim was in 1 elected F R.S

The putrefactive bases of putrid meat, a pop subject at the end of the first decade of this century, attracted his attention Dixon and Taylor claimed an extract of placenta had a pressor effect but Rosenh showed that if there was no putrefaction there wa pressor effect

He retired early giving up his readership of chemistry in the University of London in 1920 devoted himself to his rock garden But his restless of inquiry was not to be gainsaid and he intere himself in the pigments of edelweiss and young leaves

After a few years of retirement he came as a volun worker to the National Institute for Medical Rese at Hampstead and so began a second fruitful peri outstanding contributions to biochemistry With wife and Dudley and later with Dudley and Star he elucidated the distribution and constitution of natural bases of unknown function spermine spermidine present in many mammalian tissues

With Webster who had already worked out a valu technique for the testing of antirachitic materials rats, he began his important studies of vitamin Rosenheim, with Drummond and Coward had alre shown in 1925 that the precursor of the active subst found in foodstuffs on exposure to ultraviolet light known as vitamin D was in the sterol fraction He followed this up with Webster and was able to that the substance responsible for the effects the vitamin was ergosterol This culminated in hands at the Institute in the isolation of vitamin D

Rosenheim also made a notable contribution to knowledge of vitamin A With Drummond he showed the vitamin-content of cod liver oil was approxima proportional to the colour intensity produced by addi of arsenic trichloride This test, naturally unsuitabl pharmaceutical laboratories because of the arsenic modified by Carr and Price who used antimony trichl ide The commercial use of other fish-oils which Ro heim found to be richer in vitamin A than cod live began about this time

In 1932 the chemistry of the sterols and related acids had reached an impasse The structures ass to these substances looked improbable Diel obtained chrysene by selenium treatment d emphasised the X-ray findings in the study of sterol olecules Rosenheim and King then advanced a volutionary formula which has stood the test of time d has led to great advances in the chemistry of the rols, bile-acids, heart-poisons, sex hormones, and nstituents of the adrenals

Rosenheim was a remarkable man He had a phenomal memory, and having read widely and contemplaely he was a mine of reliable information on physioical chemistry He loved to get, as he said, to the ttom of things and spent hours in libraries tracing corded observations to their origin He was a meticuus worker in the laboratory and extremely methodical is sagacity, wisdom, and knowledge were available to e humblest inquirer, and no-one could wish to meet a ore helpful colleague

H K

Mr J F BALLARD, director of the Boston Medical brary, died on May 15, at the age of 76 He was conlting librarian to the Boston City Hospital, the Boston iversity School of Medicine, Tufts College Medical hool, Boston, and the Armed Forces Medical Library Washington In 1920 he visited Europe in the interest the China Board of the Rockefeller Foundation to v a medical library for the Peiping Union Medical llege in China During the sixty-two years he served librar he was active in building up its collections e med cal incunabula, which he began to assemble h the te Dr William Norton Bullard, have grown to r 800 books and medieval manuscripts In 1944 he plishe a scholarly catalogue of the collection and he wc ng on the preparation of a second volume, agin he catalogue up to 1955, at the time of his th e classification scheme which he devised has ed by many medical libraries

Notes and News

WORLD HEALTH ASSEMBLY

THE eighth World Health Assembly is now being held in Mexico City under the presidency of Dr Ignacio Morones Prieto On May 12 Dr M G Candau, director general of W H O , presenting his annual report, declared that the two greatest challenges to the Organisation are the eradication of malaria and the use of atomic energy in medicine and public health Impressive results had been achieved in the fight against malaria As a result of energetic action by national administrations, often aided by W H O and other international and bilateral agencies, more than 230 million people had been either freed or protected from malaria "The future efforts to bring safety to over 370 million people still exposed to malaria must take into consideration the fact, now apparently established, that anopheline mosquitoes which transmit malaria may become resistant to insecticides" The anti malaria drive was now at the cross roads "If we continue present campaigns not only do we face the danger of local vectors developing resistance to insecticides, but we may also expect that governments would not continue indefinitely providing the funds necessary for these campaigns" The only course open was to abandon the old line of action aiming at malaria control and to concentrate on total eradication.

At a later meeting the Assembly elected the following six States to designate members to sit on the W H O Executive Board for a three year term Argentina Pakistan Philippines, Ecuador, Portugal, and Finland Members from the following States have retired Brazil, Canada, Denmark, Iran, New Zealand, and United Kingdom

Mr Milton Siegel, assistant director general in charge of the department of administration and finance, informed the programme and budget committee that the Organisation s financial position had improved as a result of progress in collecting the arrears of governments' contributions The arrears of active members were now only $400,000

Dr Andrija Stampar, president of the Yugoslav Academy of Sciences and Arts and president of the first World Health Assembly, was awarded the Léon Bernard foundation prize, in recognition of his "outstanding contribution and practical achievements in the field of social medicine"

THE ROYAL SOCIETY

THE annual conversazione of the Royal Society was held on May 19 As the custom is, those for whom the study of flora and fauna had lost part of its freshness could contemplate some newly evolved features of the universe—the atomic billiards that goes on in a nuclear reactor, for instance But, for all the exciting things that physics and chemistry and the rest had to show, it was the flora and fauna that made the most striking exhibits

The Marine Biological Association of the United Kingdom made their usual delightful contribution to the occasion, this time with a show of invertebrate animals from the tidal zone of the sea shore There were busy sea slaters, lethargic scorpion spider crabs, looking harmless enough for paddlers (but no one tested them), glinting jewel anemones, and a great deal more Near by, Dr W H. Thorpe, F R S , presented some of the results of his remarkable work on the analysis of bird song Like most animal sounds, bird songs are hard to describe in words, and even the most musical people are often at a loss to remember minute details of songs without the aid of a suitable notation Moreover, the naked ear can seldom catch the elaborate sound patterns of high frequency high speed, and rapid modulation Most of these difficulties have been overcome by new methods of recording the song is first recorded in the usual way and then played back into an instrument which analyses the pitch and strength of the successive notes The result is something like a musical score and an expert can read it without actually playing it This method has been used to uncover the singing habits of the chaffinch If a chaffinch is kept in a sound-proof aviary and never hears other birds holding forth in springtime, it can itself manage only a very simple and imperfect song But it produces a typical song if it can hear other chaffinches, even when they are a long way off and there are other birds making quite a clamour close at hand Most of this learning can be acquired in its first spring as a fledgling, before it has tried to sing itself, and it may be that it learns something before it comes out of the egg The song, once learnt, is bred for ever. A strange finding is that if several chaffinches are kept together in a sound-proof aviary they teach each other to sing a complex song but it is very different from that of a wild chaffinch. Dr Thorpe has noticed that birds in a particular region sing in a kind of local dialect but he did not say whether the accent of the birds near his department at Cambridge was highly thought of in the chaffinch world.

Dealing with rather larger animals Mr F C Fraser and Mr P E Purves, of the British Museum set out the evidence for the belief that, contrary to earlier views, whales can hear very well (but direct proof was lacking for there were no whales in Burlington House). The sound path is essentially the same as in terrestrial mammals, with precisely the modifications of structure of the tympanic membrane and ossicles required for receiving water-borne vibrations. Elsewhere Dr A J Cain and Mr I. C J Galbraith of Oxford illustrated the effect of geographical isolation on the evolution of birds in the Solomon Islands. Most of the land birds there came originally from New Guinea, and some of them now show clearly marked division into geographical races (or subspecies) in the various islands. Some birds, however, are still very much the same throughout the islands, and they are judged to be relative newcomers.

In the study of an animal often less agreeable than all these Dr A J Buller and Dr A C Dornhorst of St Thomas's Hospital, displayed on an oscillograph screen the features of sound transmission through the normal human chest. Sounds were passed via the mouth into the respiratory tree and there was a microphone on the chest wall which amplified and recorded the sound output on the cathode-ray tube. By this means it will be possible to analyse long recognised physical signs of chest disease more precisely than Laennec or any of his successors have hitherto been able to do. A very crowded exhibit was that of Dr R A Weale of the Institute of Ophthalmology who demonstrated a stereoscopic illusion—though not everyone could make the swinging pendulum behave as it should have done. On the other hand there were no illusions about Mr John Hadland's high-speed cinematography in the film presented by Dr D A McDonald of St. Bartholomew's Hospital. The traditional falling cat was as popular as ever in slow motion and Dr McDonald then explained how the injection of gas bubbles had made possible the filming of the blood flow in the arteries of experimental animals. The film's star was a stout-hearted young man who stood up to a punch in the eye so that his reactions could be demonstrated in detail.

University of Cambridge

On May 14 the following degrees were conferred:

M.B., B.Chir.—L M Barrett.
M.B.—J S Garfield.

*By proxy

University of Leeds

Dr G R Hargreaves has been appointed Nuffield professor of psychiatry and head of the department of psychiatry from Oct. 1.

Dr Hargreaves qualified in 1932 from University College Hospital. After holding resident posts at several London hospitals he was appointed assistant physician to the Tavistock Clinic. In 1940 and 1941 he served as command psychiatrist to Northern Command and in 1941 he was appointed psychiatric adviser to the War Office Directorate of Selection of Personnel. In 1942 the Directorate of Army Psychiatry was set up in the Army Medical Department of the War Office and Dr Hargreaves served as assistant director until 1945. On demobilisation he was appointed O.B.E. From 1945 to 1948 he held the post of chief medical officer to the Unilever Company. During this period he was also lecturer in mental hygiene at the London School of Hygiene and Tropical Medicine. Since the end of 1948 he has been chief of the mental health section of the World Health Organisation.

University of Wales

Dr Scott Thomson has been appointed part-time professor of bacteriology in the university at the Welsh National School of Medicine, Cardiff.

Dr Scott Thomson is director of the regional public-health laboratory of the Medical Research Council at Cardiff and has been lecturer in bacteriology in the medical school since 1946. He is also honorary consultant bacteriologist to the Cardiff Royal Infirmary and consultant adviser in bacteriology to the Welsh Regional Hospital Board. He graduated in medicine from the University of Edinburgh in 1933 and after holding a house-appointment at the Edinburgh City Isolation Hospital he took the D.P.H. Shortly before the war he was Lewis Cameron lecturer in bacteriology at the University. In 1940 he received the gold medal for his M.D. thesis and the same year he took the M.R.C.P.E. Later with the rank of major in the R.A.M.C. he served as bacteriologist of the penicillin research team set up by the War Office in 1943.

University of London

The following have passed the final examination for the degree of M.B., B.S.:

Honours.—H B Anstall (c), Guy's; Alison M Armstrong (a), Westminster; Kathleen M Barber (b), Roy. Free; D H Beigel (c), Bart's; P S Boulter (b, d, *University Medal*), Guy's; Eileen R Busby (d), Charing Cross; J L Dawson (a), King's College; Stanley Feldman (c), Westminster; Vorna P Firth (b), Guy's; R. C Hallowes (e), St Thomas's; B A L Hurn (d), Bart's; N. R. Kemp (a), Univ. Coll.; Peter McDonald (c), Bart's; Joyce M Pallett (c), Univ. Coll.; Hazel M Price (e), Roy. Free; K. P Robinson (c), Westminster; N E. Rust (c), St Mary's; Enid H Shaw (c), Roy. Free; R. A Stroud (c, e), Bart's; Averil M Walker (e), Univ. Coll.

(a) Distinguished in pathology and bacteriology. (b) distinguished in medicine. (c) distinguished in applied pharmacology and therapeutics. (d) distinguished in surgery. (e) distinguished in obstetrics and gynæcology.

Pass.—W N Agnas, Nazir Ahmed, Ann K Alstrop, R H Anderson, B G Andrews, J C Anthony, Davies Martino, N K Armstrong, D L Arnold, M. J Atwill, Malcolm Aylett, R. D Bailey, G C W Baker, R. Sanderson Wells Lecture

Prof R A McCance F.R.S., will give the Sanderson Wells lecture on Tuesday, June 14 at 4.30 P.M. at the Middlesex Hospital, London, W 1. He is to speak on Old Thoughts and New Work on Breads White and Brown.

Royal College of Obstetricians and Gynæcologists

At a meeting of the council held on May 21, with Sir Arthur Gemmell, the president, in the chair, the following were elected to the council

As representatives of the fellows —J F Cunningham, Dublin T N A Jeffcoate Liverpool, H J Malkin, Nottingham J H Peel, London

As representatives of the members —J G Gallagher, Dublin, T L T Lewis London S D Loxton, Bristol

The following were admitted to the fellowship

D R Beaton, R K Bowes, J C Coetzee, Mary D Daley, L L Davey, Ian Donald A S Duncan, H R Duval Amy D Engineer, R Magnus Haines I MacG Jackson, D F Lawson A A Moon Roland Nattrass, J C Newbold, R. C Percival B H Shdares Hugh Stirling C W Taylor

The following were admitted to the membership

R. H O Bannerman David Barron H R C Benny D B Brown T I *Cope*, A C *Coulthard* K D *Drayton* W A W Dutton B A Gavourin, H S Gavourin, Tara Sankar Ghosh, A. R B Harston, Josephine M R Heber Beryl O Howie, P E Jeffery, Beryl M Joles, G W Korn, Wendy E Lewington J D Llywelyn Jones, Philippa M Ludlam J G Mathie Appuhandy Ariyaman Mahanama Mendis, David Methuen, Catherine H Mitchell, Nanda Gopal Mukherjee, Rathindra Nath Nag, R T Sears Harendra Bahadur Sinha, D H K Soltau A E M. Stevenson, O S Treisman, Yin Kai Tsao, J K Tully J A M V Belkum

Dr A M Sutherland was appointed William Blair Bell lecturer for 1955, and Prof Louis Hellman (New York) Green Armytage lecturer for 1956

University of Otago, New Zealand

Dr Harold Bourne has been appointed lecturer in psychiatry and junior physician at the medical school, Dunedin.

Faculty of Radiologists

The annual meeting of the faculty is to be held in Bristol on June 10 and 11 The subjects chosen for discussion are Ankylosing Spondylitis, Postgastrectomy Syndromes, Radio therapy of Rheumatic Diseases, and the Radiosensitive Bone Tumours Further details may be had from the secretary, 45, Lincoln's Inn Fields, W C 2

Medical Association for the Prevention of War

This association will hold a conference on Saturday, June 4, at 2 30 P M at 45, Russell Square, London, W C 1, on the *Medical Effects of Radioactivity* The speakers will include Dr George Discombe, Dr W R Doll, and Dr Richard Dobbs Dr Duncan Leys will be in the chair

General Practice Reform Association

The first annual general meeting of this association was held in London on May 21 with Dr Robert John, the president, in the chair Dr J J Segall, chairman of the executive committee, said that the association's purpose was to serve the real and long term interests of the profession as a whole and of the health services, with particular regard to general ctice, and consequently, because of present conditions, serve also the special interests of principals with medium small lists, assistants and other unestablished practitioners, the future generations of new doctors. The G P R.A ramme included the creation of regional health authorities ing about a unitary system of health services administra and organisation, the reduction, by stages, of the mum number of National Health Service patients per itioner from 5500 (the number at present permitted for ctitioner who employs another doctor as a full time ed assistant) eventually to 2000, the provision of health s in suitable localities, the replacement of the assistant system by a satisfactory general practitioner training e, with the trainee employed by an appropriate rity, and the restoration to N.H S patients of full freedom of change of doctor The G P.R A did not wish to rival the older medical organisations, and it was hoped that stronger relations with them would develop Dr L Russell, deputy chairman of the executive committee, speaking of the Minister of Health's committee on medical man power, expressed a hope that the estimates of the number of general practitioners required would be based on a maximum of 2000 N H S patients per practitioner A resolution was passed urging the Ministry of Health, the Medical Practices Committee, and the General Medical Services Committee (or counterparts in Scotland) to take steps to obtain consideration for unestablished practitioners of executive council practice vacancies, including on and mainte of a central register of the appointn

British Association of Pædiatric Surgeons

The association will hold its annual meeting in Glasgow from June 15 to 17, under the presidency of Mr Matthew White Further particulars may be had from Mr W M Dennison, the Royal Hospital for Sick Children Glasgow, C.3.

Hospital Pharmacists

The salaries of pharmacists working in hospitals or health centres have been increased, from April 1, by sums ranging from £50 to £125 a year according to grade and length of service

Prison Medical Service

The annual conference of prison medical officers and psychologists was held at the Home Office on May 20 Dr H K Snell, director of medical services of the Prison Commission, was in the chair The speakers included Dr J D W Pearce, Dr I A Angus, and Dr C F T Saville

Ciba Foundation

On Wednesday, June 15, at 5 P M, at 26, Portland Place, London, W 1, Dr H Olivecrona, professor of neurosurgery at the Karolinska Institute, Stockholm, will give the seventh Ciba Foundation lecture He is to speak on Hypophysectomy in Diabetes

British Orthopædic Association's Belgian Visit

On April 22 and 23 Prof Bryan McFarland the presid and some twenty members of this association attended the spring meeting of the Société Belge d'Orthopédie et de Chirurgie de l'Appareil Moteur at Brussels at the invitation of the president, Dr Robert Soeur A report on the functional results of arthroses was presented by Dr de Racker

The 48-hour Week in the N H S

A conference of the National Union of Public Employees, reported in the *Times* of May 24, instructed the union's executive council to press for a 44-hour week for ancillary staff of the National Health Service The present 48-hour week was held responsible for the serious drift of labour from the service, the failure to attract new entrants, and "widespread discontent now existing among ancillary st

Rockefeller Grants

The Rockefeller Foundation has made a five year grant of £15,000 for a new department of occupational health at the London School of Hygiene and Tropical Medicine It has also made a £12,500 grant for a three-year period to assist research in the department of physics at King's College Hospital under Prof J T Randall, on the structure of nucleic acid

Sir Harold E Whittingham
K.C.B., K.B E., LL.D Glasg F.R C.P F R C S E
DIRECTOR OF MEDICAL SERVICES BRITISH OVERSEAS AIRWAYS
CORPORATION

On the morning of Jan 10 1954 the Comet air liner ALYP took off from Rome airport en route for London with 35 people on board About twenty five minutes later a sound like an explosion was heard and the aircraft in pieces crashed into the sea near Elba There were no survivors but within about four hours 15 bodies were recovered from the sea in an area some $1^1/_4$ miles in diameter All but 1 of the bodies were floating face downwards when found 5 were naked or almost so retained only a few garments and 6 were still well clothed 11 of these people had almost certainly been in the rear part of the main cabin at the time of the disaster and those who had occupied the back seats were more [illegible] up than those from more [illegible] lies were taken to Elba and between Jan 12 and Jan 14 all but 1 were subjected to detailed necropsy by Prof A Fornari of Pisa

On the evening of April 8 another Comet air liner (G-ALYY) disappeared on a routine flight from Rome to Cairo with 21 people on board The following evening 5 bodies were found floating on the sea near Naples and picked up by H M S *Eagle* As on the previous occasion all but 1 floated face downwards. It is estimated that they were in the water for about twenty two hours including most of the daylight period of April 9 A 6th body was washed ashore ten days later at Paola Of these bodies 1 was *almost fully clothed* 1 was scantily clad, and the other 4 were practically naked All were passengers from the rear part of the main cabin the front seats had been unoccupied The bodies retaining most clothing had again occupied the rearmost seats 5 of the bodies were subjected to necropsy in England by Dr Donald Teare on April 12 and 13 and the remains found at Paola were examined by the Italian authorities

Many intricate investigations spread over about nine months were undertaken at the Royal Aircraft Establishment and elsewhere to find out the exact nature and basic cause of the disasters and hence to devise measures to prevent their recurrence In this work the medical evidence assumed immediate importance owing to the absence, for some considerable time of wreckage which would facilitate reconstruction of the Elba accident Owing to the depth of the sea off Naples salvage operations were impossible and no significant wreckage was forthcoming consequently the medical evidence in this instance was of particular importance in so far as it showed that both accidents had essentially the same effects on the passengers.

The necropsy findings are of interest quite apart from their place in the inquiry owing to their somewhat unusual nature and the unique circumstances in which the injuries were sustained In modern air liners it is necessary to pressurise the cabin to protect passengers from the hazards of anoxia and decompression sickness at high altitude At the time of the disasters both Comets had reached an altitude of about 30 000 ft during the initial climb At this height the air pressure inside the cabin is about 7 5 lb per sq inch (388 mm Hg) above that prevailing outside In recent years there has been much speculation about the possible consequences of a sudden structural failure causing very rapid ("explosive") decompression In particular damage to the lungs has been feared owing to the rapid expansion of intrapulmonary gas (Armstrong 1936 Lovelace and Gagge 1946 Fulton 1948) Clearly such a possibility had to be considered in the Comet victims for break up of the fuselage at 30 000 ft, whatever the cause would be accompanied by rapid decompression Nevertheless any lesions due directly to decompression would be associated almost inevitably with others due to violent impact with parts of the aircraft or its furnishings Another possibility was blast injury due to some kind of explosion Moreover all injuries inflicted in the aircraft might well have been complicated by the effects of a free fall from high altitude by impact with the sea and by effects of exposure while floating on the sea in the vicinity of the crash

The medical inquiry had three *main* objectives (1) to record all lesions found at necropsy (2) to identify the cause of death, and (3) to ascertain in accordance with these facts the probable nature and sequence of traumatic events We do not give a full description of the necropsy findings because a brief summary of the outstanding features will serve as adequate introduction to the description of the necessary research with which we were primarily concerned

The major injuries in all the bodies from both accidents were remarkably uniform All but 5 of the 19 bodies examined had ante mortem fractures of the skull and 15 had similar injuries to the thoracic cage mostly of exceptional severity Spinal fractures and costo-vertebral dislocations were common Limb fractures found in 13 cases, were identified as predominantly post mortem Grave internal injuries were present in all the bodies even in those with little external injury Thus, hæmothorax *of* 0 3–2 0 litres was present in 10 *cases* and the lungs were severely damaged in all 19 In no case however was there evidence of drowning The heart was ruptured in 4 bodies and the great vessels were torn in 13 *Intra abdominal injuries were rather less common* but hæmoperitoneum (up to 1 litre) was present in 14 cases and hepatic laceration or pulping was invariable Only 5 cases had tears of the spleen In addition areas of altered skin were observed in 14 of the Elba victims and in 4 from Naples in the former they were likened to burns or scalds whereas in the latter the change was apparently in pigmentation

Analysis of these findings led to the conclusion that three aspects of the problem needed special investigation if the medical evidence was to be of positive value in reconstruction of the accidents (1) the *ætiology of the pulmonary lesions* (2) *the cause of the skin lesions* and (3) the feasibility of distinguishing between ante mortem and immediately post mortem injuries with special reference to the effects of violent contusive trauma The last point is important in any attempt [illegible] time sequence

Pulmonary Lesions

PATHOLOGY

Severe injury to the lungs was an invariable finding The predominant *naked-eye lesions* were [illegible] bruising laceration pulping and areas of [illegible] with subpleural bullæ

Irregular *lacerations of various depths were* [illegible] the lungs *in most cases* They were [illegible] the lower lobes, chiefly on the diaphragmatic surfaces, and sometimes extended into areas of complete pulping Only occasionally could the lacerations be attributed to penetration by fractured ribs, they were prominent in the 2 cases in which the thoracic cage was intact The margins of the tears were clearly hæmorrhagic in all but 2 cases These 2 bodies (numbers 14 and 15 from Elba) also differed from the others in showing no hæmothorax It seems likely that the pulmonary splits in these 2 cases occurred after the circulation had ceased

Subpleural hæmorrhages and congestion were present to some extent in all instances, giving a mottled appearance to the surface Slices showed that the hæmorrhagic zones often extended deeply into the lung, and that hæmorrhages were scattered throughout the pulmonary parenchyma In no case did the subpleural hæmorrhages present a definite linear pattern of "rib-markings" In contrast with the dark areas of congestion and bruising, other parts of the lungs seemed unusually pallid, bloodless, and expanded Tense subpleural bullæ occurred in these areas, especially in the upper lobes

Portions of the lungs from 18 bodies were examined microscopically at Farnborough The Elba specimens had been fixed in 10% *formalin, and those from Naples in* Zenker-formalin Paraffin sections were stained for general histology with Ehrlich's hæmatoxylin and eosin, and by the Masson trichrome method Wilder's silver chnique was used for the demonstration of reticular res, and mucus was identified by the periodic acid-iff reaction Other pieces of lung tissue from each y were embedded in gelatin by the procedure des-d by Baker (1946), frozen sections 15–25 μ thick stained for neutral fat with alcoholic solutions of n III and IV, or Fettrot 7B (Pearse 1954)

tensive disorganisation of the finer structure of the was found in every case The outstanding lesions traumatic emphysema, hæmorrhage, vascular gement, and fat embolism

most striking feature in the sections was the ce of adjacent large areas of emphysema and rhagic consolidation So far as could be deduced he samples taken for histology, these features were but not uniformly distributed throughout the in places the emphysema was massive, notably parts of the upper lobes where macroscopic bullæ en observed at necropsy The emphysema was traumatic (figs 1 and 2) In the affected parts lls of alveoli, alveolar ducts, and respiratory and al bronchioles were torn, with consequent formation of irregular spaces varying greatly in size, the largest being about $^{1}/_{4}$ inch in diameter Remnants of the torn alveolar walls projected into the spaces, and in sections stained by Wilder's method reticular fibres were seen protruding from the torn edges As might be expected, such changes were not restricted to the pre-existing air spaces of the lung but were accompanied by interstitial emphysema due to the formation of direct communication between the air spaces and the connective tissues of the bronchovascular planes and interlobular septa The subpleural bullæ were of this type, evidently *caused by escape of air into the deeper layers* of the visceral pleura (fig 1) The severity and distribution of traumatic emphysema bore some relation to the normal anatomical pattern of pulmonary lobules Thus, distended areas with great destruction of lung parenchyma were commonly adjacent to areas of collapse or of relatively normal lung and separated from them only by interlobular septa Nevertheless collapse, hæmorrhage consolidation, and emphysema could, in places, be seen side by side in the same lobule In some cases the bronchi and bronchioles contained plugs of material including epithelial cell debris, a few red blood cells, and matter, presumably mucus, which stained with periodic acid Schiff reagent (fig 3)

In all but 2 bodies the blood vessels and lymphatics of the lungs were congested There was gross intra-

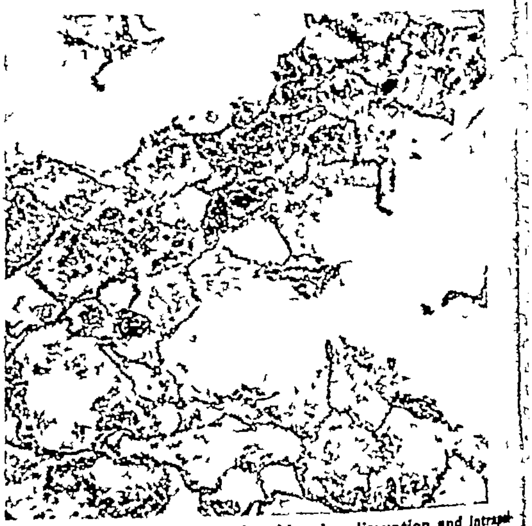

Fig 2—Naples accident body C. Alveolar disruption and intrapulmonary hæmorrhage in upper lobe of right lung (Hæmatoxylin and eosin ×52.)

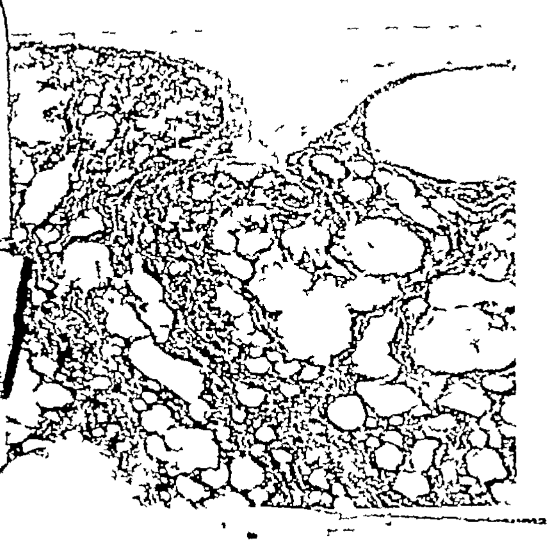
pulmonary hæmorrhage, but this varied considerably from one part of the lung to another Much of the blood seemed to have come from the innumerable disrupted capillaries, but arterioles and even small arteries were occasionally found opening directly into the air spaces Over large areas the alveoli were completely packed with blood, giving a condition of hæmorrhagic consolidation or hepatisation, and in places the pleura was separated from the underlying parenchyma by extravasated blood Some of the alveoli and emphysematous spaces also contained what appeared to be œdema fluid and amorphous debris Bodies 14 and 15 from Elba, however, showed little evidence of intrapulmonary exudation or bleeding, although there were severe traumatic emphysema

In several specimens there were early signs of post-mortem autolysis and putrefaction due to bacteria which could be seen in the sections, particularly in regions of gross hæmorrhage In these cases it was not difficult to distinguish between smooth walled spherical spaces produced by the action of gas forming organisms the irregular cavities of traumatic emphysema



matic

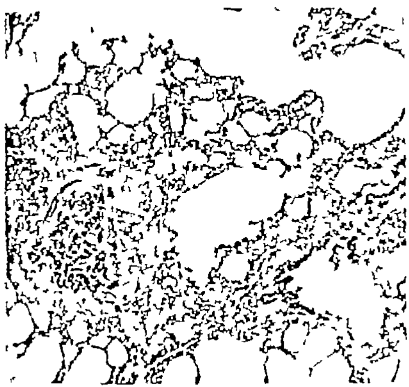


Fig. 3—Elba accident: body 4. Bronchiole occluded by cell debris and mucus, and another partially denuded of epithelium. (Hæmatoxylin and eosin. ×52.)

The frozen sections revealed pulmonary fat embolism (fig 4) in 12 bodies. The amount was small in most cases but in 3 (2 from Elba and 1 from Naples) it was considerable. The quantity of intravascular fat observed in the few frozen sections examined from each case does not, of course, necessarily indicate the total embolic fat-content of the lungs and must therefore be interpreted with due reserve. However, the mere presence of fat-embolism is of interest in so far as it might help to determine the sequence of injuries. It is unlikely that the fat originated within the lungs. Ante-mortem fractures are usually assumed to be the source of pulmonary fat-embolism but this is not always so (Robb-Smith 1941). All 12 cases with which we are now concerned had fractures with local ante-mortem characteristics, but 1 case showing considerable fat-embolism was also 1 of the only 2 bodies with an intact thoracic cage, having ante-mortem fractures only of the skull.
